ENCYCLOPÆDIA BRITANNICA.

GRANVILLE, the ancient *Grannonum*, a fortified seaport town of France, department of La Manche, at the foot of a steep, rocky promontory projecting into the English Channel, 30 miles S.W. of St Lô. It is surrounded by strong walls, and the streets are narrow and steep. The only remarkable building is the parish church, a venerable Gothic edifice. The harbour is spacious and secure, but dry at low water. Works, however, are now in progress for the improvement of the harbour generally, and for the construction of wet docks. The inhabitants are chiefly engaged in the coasting trade, or in the cod and oyster fisheries. Ship-building is also carried on. It has a tribunal of commerce, an hospital, public baths, and a naval school. Granville was bombarded and burned by the English in 1695, and partly destroyed by the Vendean troops in 1793. Pop. 8347.

GRAO, a seaport town of Spain, prov. of Valencia, and four miles E. of that town. It is situated at the mouth of the Guadalviar or Turia; and it has a town-house, prison, parish church, and two schools. Pop. about 3000, chiefly fishermen.

GRAPE, the fruit of the vine. See HORTICULTURE, and WINE-MAKING.

GRAPE-SHOT, in *Artillery*, consists of a quantity of shot piled round an iron spike which is placed in a strong canvas bag, the whole being firmly corded together so as to form a cylinder adapted to the calibre of the cannon. It differs from canister or case-shot in that the latter kind is composed of balls packed into a tin canister with a wooden bottom.

GRAPHITE (γράφω, I write), otherwise called *plumbago*, and often improperly *black lead*, is a mineral carbon with a slight admixture of iron. It may be made artificially by exposing iron with excess of carbon to a violent heat for a considerable length of time, when a real carburet of iron will be formed; whereas in the native specimens the iron and charcoal are only mechanically combined. The finest graphite occurs at Borrodale in Cumberland, and is appropriated exclusively to the manufacture of pencils. The coarser varieties are used for making crucibles and portable furnaces, for which purposes this substance is peculiarly fitted from its infusibility; and it is also much used for giving a gloss to the surface of cast-iron goods, as well as to diminish friction between rubbing surfaces of metal or wood in machinery. The properties and geographical distribution of graphite are more particularly noticed under MINERALOGY.

GRAPHOMETER, a mathematical instrument, otherwise called a *semicircle*, used in land-surveying to observe any angle the vertex of which is at the centre of the instrument in any plane, and to find how many degrees it contains.

GRAPNEL, or GRAPLING, a kind of small anchor with four or five flukes or claws, chiefly used to secure small boats.

GRASMERE, a village of England, county of Westmoreland, picturesquely situated at the head of the lake of the same name, 4 miles N.W. of Ambleside. In the burial ground adjoining the parish church are interred the remains of the poet Wordsworth. The lake of Grasmere is about a mile in length by half a mile in breadth, and is surrounded by mountains presenting beautiful scenery.

GRASS. See *Gramineæ* in index to BOTANY, and AGRICULTURE.

GRASSE, LA, a town of France, capital of a cognominal arrondissement in the department of Var, 23 miles E.N.E. of Draguignan. It occupies a highly picturesque situation on the southern declivity of a hill, facing the Mediterranean, from which it is about seven miles distant. The streets are narrow, steep, and winding, but the houses are generally well built. The climate is salubrious, and the town is well supplied with water from a rivulet which rises above it. It has a large Gothic church of ungainly appearance, three hospitals, town-hall, exchange, theatre, communal college, and public library. Next to Paris it carries on the largest manufactures of perfumery in France. The vicinity abounds in citrons, oranges, lemons, figs, and pomegranates, and in flowers used by the perfumers. Fine marble and alabaster are also found in the vicinity. Pop. (1851) 11,540.

GRASSHOPPER. See index to ENTOMOLOGY.

GRATIANUS, AUGUSTUS, son of Valentinian I., succeeded to a share of the Western Empire on the death of his father in A.D. 375. After a reign of eight years he was murdered by the partizans of a rebel aspirant to the imperial throne. Though only twenty-four at the time of his death, he had given proof of possessing many excellent qualities. He was just and gentle, zealous for the public good, and a true friend of Christianity.

GRATIANUS, a Benedictine of the twelfth century, is said to have been born at Chiusi in Tuscany, and to have resided at Bologna. His name has been preserved by his collection of the canons or decretals of the church, published at Mainz in 1472, under the title of *Decretum Gratiani*. This work was a great improvement upon its predecessors; but from the want of standard authorities and a sound principle of criticism many of the canons in it are quite apocryphal, and the text in many places very corrupt. Gratian, however, was himself well aware of the defects of his work, and warns his readers not to put too much faith either in his statements or his conclusions. He is often guilty of the most absurd self-contradictions in his endeavour to reconcile incongruous canons; and is accused by the Abbé Fleury of unwittingly extending the authority of the Pope, by his doctrine that the Pope was not himself subject to the canons. As Gratian's errors were leading to awkward results, an edition of his *Decretals* was published in 1582 by order of Gregory XIII.; in which the more flagrant mistakes were corrected. A treatise, *De Emendatione Gratiani*, by Antonius Augustinus, is an indispensable supplement to Gratian's own work.

GRATIUS, a Roman poet, whose real name has been almost supplanted by the epithet FALISCUS, added by a modern commentator. He was a contemporary of Virgil and Ovid, and wrote a book on hunting called *Cynegeticôn Liber*, which seems to have fallen wholly into oblivion before the time of Caracalla. At least, we find in the reign of that emperor the Greek Oppian writing on a cognate subject, and boasting of having struck out an entirely new path for himself. There is only one MS. of the *Cynegetica* extant, and even it is very corrupt. This, added to the arbitrary use of many individual words, the forced constructions, and a general haze that hangs over the whole poem, makes it very difficult to be understood. The work professes to describe the various kinds of game, the means to be employed for their pursuit and capture, the best breeds of horses and dogs, &c. The facts on which the poem is based are derived chiefly from Xenophon. The best editions of Gratius are those of Burmann and Wernsdorf. There is an English verse translation of the poem by Christopher Wase, London, 1654; and a German one by S. Perlet, Leipzig, 1826.

GRATTAN, HENRY, an illustrious Irish orator and statesman, was born at Dublin in the year 1750. His father was a barrister, and, though not remarkable for brilliant qualities, was industrious and prudent. Being a Protestant, the corporation of Dublin extended to him its patronage, in consequence of which he was elected as representative of the city in parliament, and made recorder. After passing through the usual course of scholastic discipline, which he did with much *éclât*, young Grattan was entered as a fellow-commoner in Trinity College, Dublin. Here also he greatly distinguished himself amongst contemporaries who afterwards became the chief ornaments of the senate and the bar. His original intention was to have studied for a fellowship, but the persuasions of his relatives induced him to remove to England, where he entered himself as a student of the Middle Temple. When the requisite number of terms had expired, he returned to his native country, and in the year 1772 was called to the Irish bar. His practice seems to have been small; but that his talents had already begun to make an impression, is proved by the fact, that in 1775 he was brought into the Irish parliament under the auspices of Lord Charlemont. From this period the life of Grattan became a portion, and a very conspicuous one, of the history of his country. He joined the ranks of the opposition, and the accession of strength which it thereby acquired soon became apparent. The effect of his commanding eloquence was not confined to those who listened to it in the house. He infused the patriotic spirit with which he was himself actuated into the country at large. It is allowed, indeed, that the volunteer bands, who had begun to assemble in the various parts of Ireland, acquired new confidence from the bold uncompromising tone assumed by the young speaker; and in the course of a few years their ranks swelled to the number of 80,000 men, armed, disciplined, and prepared for the field. The menacing attitude which Ireland assumed at this critical period, and the boldness with which the members of the Irish opposition, particularly Grattan, contested the supremacy of the sister kingdom, induced the British legislature, in the year 1782, to repeal the statute of the 6th of George I. By this law it had been enacted that the crown of Ireland should be inseparably annexed to that of Great Britain; that Ireland should be bound by British acts of parliament, if named therein; that the Irish House of Lords should have no appellate jurisdiction; and that the last appeal, in all cases of law and equity, should lie to the British House of Peers. For Grattan's exertions in getting this statute rescinded, his country was profuse in laudatory addresses to him; and the parliament rewarded his services by a grant of L.50,000. A more magnificent donation was intended, but Grattan declined to accept it. That bestowed was large enough to inspire envy and provoke misconstruction. The following sessions of parliament were stormy; and the young patriot had to contend, amongst others, with Mr Flood, an antagonist formidable alike by his acknowledged talents and the unscrupulous virulence of his attacks. The latter maintained that the act of repeal did not involve a renunciation of the British claims, and that therefore they might be resumed and exercised at any time. This sophistry found supporters in both houses of parliament, and the reputation of Grattan actually began to wane. But the energy and success with which he opposed Mr Ord's celebrated propositions, brought forward in 1785, fully re-established his fame. One of these was, that the Irish legislature should, from time to time, adopt and re-enact such statutes of the British parliament as related to the regulation of commerce. In opposing this proposal Grattan put forth all his powers, and from this period he began to be acknowledged as the leader of the country party, and as the head of the Irish Whig Club. The members of this association were reciprocally bound not to accept office under any administration which had not for its avowed principle the conceding of certain popular measures. These consisted of a bill to make the great officers of the crown responsible for their proceedings; a bill to prevent revenue officers from voting at elections; and a place and pension bill. Several other important subjects engaged the attention of Grattan at this period; and amongst these was the establishment of a provision for the clergy independent of tithes. He also brought in a bill to encourage the improvement of barren lands, by exempting reclaimed wastes from paying ecclesiastical dues during the space of seven years. But both these measures were rejected by the legislature, principally through the influence of the established church.

About the same period Grattan strenuously advocated an extension of civil rights to his Roman Catholic countrymen. That a Protestant statesman should exert himself in behalf of those who professed a religious creed different from his own, was, at the time when Catholic emancipation was at length conceded by the British parliament, a matter of such frequent occurrence, that no personal claim to distinction could be raised upon that ground: to entertain such sentiments was not considered as sufficient to subject the person entertaining them to public suspicion as one infected with pernicious opinions. But during the early career of Grattan the subject was viewed in another aspect, and through a different medium. In Ireland, whilst the heads of the Protestant church, with the majority of the Protestants, were arrayed in opposition to any concession to the Catholics, in England the tide of vulgar prejudice ran so strongly in the same direction, that a great civil convulsion had nearly arisen out of it. When these facts and circumstances are taken into consideration, the conduct of Grattan will appear in its true light, as that of a wise statesman, and a fearless patriot. His principal object was to obtain the elective franchise for the Catholics; but the administration of that day indignantly rejected the prayer of their petitions.

On the arrival of Earl Fitzwilliam, as lord-lieutenant, in 1795, Mr Grattan attached himself to that highly popular nobleman, and under his auspices originated many plans which had for their object to promote the peace and prosperity of his native land. But the recal of his lordship put a stop to all amelioration, and at the same time generated universal discontent, which was increased by the creation of new sinecures, and the lavish profusion of titles. The consequences were memorable and instructive. The society of United Irishmen, whose ostensible object was reform, but who really aimed at the independence of Ireland, acquired new courage from these dissensions, and some even proposed to establish a republic in that country. The triumph of the French Revolution had no doubt inspired these daring projectors with hopes of success. A large portion of the people adopted their principles; military associations were formed, and numbers disciplined and armed; whilst an intercourse was opened with France, by which succours and assistance were liberally promised. From the commencement of the rebellion which ensued, Mr Grattan advised measures of conciliation; and when he saw that there was no hope of stemming the general movement, he withdrew from parliament, and retired to his country residence.

But the grand project of Mr Pitt for effecting a union between Great Britain and Ireland summoned him from his retirement. He obtained a seat in parliament for the express purpose of opposing that measure, which, he maintained, would prove fatal to the best interests of Ireland. Its success did not, however, prevent him from accepting a seat in the imperial parliament, and there employing his talents and eloquence for the benefit of both countries. He was chosen, in 1805, to represent the small borough of Malton; and in the year following he was returned as one of the members for Dublin. Throughout the remainder of his career, his public conduct continued to evince the purest patriotism and the most undeviating consistency, illustrated by an eloquence fraught with the finest inspirations of genius and liberty. Notwithstanding the uniform and vehement opposition of the corporation of the city which he represented, he continued to advocate the Catholic claims with equal zeal and ability. Accordingly, towards the close of his life, we find him complying with an unanimous requisition on the part of the Catholics of Ireland, to present their petition to the British parliament, and to give it his support. Some of his friends represented the fulfilment of this duty as incompatible with his health, which had now begun to decline; but he nobly replied, that "he would be happy to die in the discharge of his duty." This event did actually take place; for he expired on the 14th of May 1820, soon after his arrival in London; and his remains were interred in Westminster Abbey.

It is comparatively easy for posterity to judge for themselves of the moral and political qualities of a statesman's character, because these can be dispassionately determined from the information afforded by history as to the course of conduct which he had pursued, and the measures which he had supported. If Mr Grattan be thus estimated, he must ever be accounted one of the most ardent, consistent, and patriotic of modern statesmen. Viewing him as an orator, we can only judge of his excellence by the report of contemporaries, who but rarely agree in such matters. We are informed that he had to contend with an indifferent voice, which was thin, and, considered simply as an organ of sound, unequal to the expression of impassioned feelings. His action, too, was seldom elegant or graceful, but it possessed a far higher character, it was forcible and energetic. Animation and ardour predominated in his manner; and his pronunciation was distinct and articulate. These are the qualities which are calculated most powerfully to impress a mixed assembly; and the effects which he accordingly produced on several occasions have not been surpassed by those of any orator of modern times. "With much of national peculiarity, but chiefly in the manner," says a very able writer;[1] "with much, too, of individual mannerism, his eloquence is, beyond all doubt, of a very high order. Perhaps, after making every deduction for obvious defects, he may even be accounted an orator of the first class. For he possesses an originality, and a force rising far above any excellencies of mere composition. Fervid, vehement thoughts, clothed in language singularly pointed and terse; an extraordinary power of invective, so remarkable indeed, that he may be ranked among the greatest masters of the sarcastic style; and, above all, and it is the distinguishing character of his oratory, a copious stream of the most sagacious and original observations, or the most acute and close arguments, flowing, though not continuous and unbroken, yet with an ease the more surprising, because they almost all are in the shape of epigrams;—these are the high and rare merits which strike the reader of Mr Grattan's speeches, and must have produced a still deeper impression upon those who heard him in his prime."—"He had deep, and warm, and generous feelings, and, when roused to enthusiasm, they sometimes found vent in simple language; but his accustomed style of epigram is far more prejudicial to the expression of passion than to the conduct of an argument; and accordingly, his declamation was by no means equal to his reasoning, if we except the vituperative parts of it, which were among the finest of all his performances. He had a lively and playful fancy, which he seldom permitted to break loose; and his habits of labour were such that he abounded in all the information, ancient and recent, which his subject required, and could finish his composition with a degree of care seldom bestowed upon speeches in modern times. Finally, he was a man of undaunted spirit, and always rose with the difficulties of his situation. He was ready, beyond any man, perhaps, who ever laboured his speeches so habitually. No one ever threw him off his guard. Whoever dreamt that he had caught him unawares, was speedily roused to a bitter sense of his mistake; and it is a remarkable circumstance, that, of all his speeches now preserved, the two most striking in point of execution are those personal attacks upon Mr Flood and Mr Corry, which, from the nature of the occasions that called them forth, must, of necessity, have been the production of the moment. The epigrammatic form in which he delighted to throw all his ideas, and the diction adapted to it, had become so habitual to him, that, upon such emergencies, they obeyed his call with the readiness of a natural style; and he could thus pour forth his indignation in antithesis and point, as easily as the bulk of mankind when strongly excited give vent to their feelings in the sort of language which, from this circumstance, we are accustomed to term the eloquence of nature or of passion.

"In the more glaring defects of what has been called the Irish school of orators, he certainly did not abound. Extravagance of passion; strained pictures of feeling; exuberance of metaphor, and of forced metaphor; and, worse than all, excess of passion expressed by unnatural and far-fetched imagery, in language quite wide of nature, and often wholly incorrect;—from these characteristic vices of his country's fanciful and ingenious and ready orators, he was exempted beyond all his contemporaries, by the chastening effects of classical discipline. Occasionally, indeed, they do break out in his compositions; but, generally speaking, it is rather in the style than in the ideas that he departs from nature; or if in the ideas, it is in his love of point, rather than in his proneness to metaphor. In one great quality he not only stands single among his countrymen, but may be pronounced eminently superior to our own greatest orators; and it is that in which all modern compositions, those of Dante and perhaps of Milton alone excepted, fall so far short of the ancient, and especially the Greek exemplars; we mean the dignified abstemiousness, which selects one leading and effective idea, suddenly presents it in a few words, and relies upon its producing the impression desired, without saying all that can be said, and, as it were, *running down* the topic. In Mr Grattan's speeches we constantly meet with opinions delivered, or illustrations flung out, in a single sentence, or limb of a sentence, and never again recurred to, although the opinion may have been so sagacious, and the illustration so happy, that a copious modern, or even an ancient of the school of Cicero, would have worked the one into a dissertation, and the other into an allegory. This is a merit of the very highest order, subject to the remarks already made upon the difficulty of making things thus lightly touched at once perceived by an audience, and the aggravation of that difficulty by the obscurity incident to the epigrammatic style."

---

[1] *Edinburgh Review*, vol. xxxviii., p. 58.

Grattan's Life has been written in 5 vols. by his son, who has also edited his miscellaneous works and his speeches in parliament. (J. F. S.)

GRATZ, a city of Austria, capital of Styria, as well as of the circle of Gratz, occupies a commanding position on both sides of the river Mur, an affluent of the Drave, 1094 feet above the level of the sea, and 96 miles S. by W. of Vienna. It consists of the city proper or inner town, which stands on the eastern bank of the river, and four extensive suburbs, having altogether a circuit of about seven miles. The suburb Murstadt is on the western bank, and is connected with the opposite bank, on which are the three others, by two bridges. The inner town occupies little more than a seventh part of the entire area, and is separated from the suburbs by ramparts and a glacis. It has a gloomy and antique appearance, and the streets are narrow and irregular. The suburbs are much more regularly built than the town itself, and contain many elegant edifices. That of Murstadt is the largest and finest. The vicinity abounds with beautiful gardens and villas. On the Schlossberg, a rocky eminence in the centre of the town, rising to the height of 300 feet, stand the ruins of the citadel, destroyed by the French in 1809. The cathedral or church of St Ægidi is a Gothic structure, erected by Frederick IV. in 1456, and contains many handsome marble monuments. Near it is St Catherine's chapel, erected as a mausoleum by Ferdinand II., who lies interred here, together with his consort, mother, &c. Gratz possesses in all ten parish churches, twelve other churches and chapels, five monasteries, and two nunneries. The *Landhaus*, where the estates hold their sittings, is a very ancient edifice, in which is preserved the ducal hat of Styria, worn by the Emperor of Austria when he receives the allegiance of the Styrians. It also contains numerous suits of old armour. The university, founded by Charles Francis, Duke of Styria, in 1586, is one of the second order, having faculties of theology, law, and philosophy. Lectures are given in medicine, but no degrees are conferred. It has a library of about 100,000 vols. and 7500 MSS., a natural history museum, &c. In 1850 it had 866 students. The *convicte*, the largest building in the town, and formerly a college of the Jesuits, is now used as a school in connection with the university. The Johanneum institution was founded in 1811 by Archduke John (Johann), from whom it takes its name. Its object is the encouragement of the arts, sciences, and manufactures of Styria by the formation of collections of various natural and artificial productions, by a library, and by gratuitous lectures delivered by professors attached to the institution. It has a reading-room, library of 32,000 vols., collections of animals, minerals, antiquities, coins, plans, &c., a botanic garden, and chemical laboratory. Gratz possesses also a gymnasium, episcopal seminary, deaf-mute institution, lunatic, foundling, and orphan asylums, a general hospital and lying-in institution, theatre, &c. It is the seat of the highest civil authorities for the duchy of Styria, and the residence of the prince bishop of Seckau. Its chief manufactures are cotton, woollen, and silk goods, iron and steel wares, leather, paper, hats, earthenware, and rosoglio. Being in the line of railway from Vienna to Trieste, it carries on a considerable trade with these places, as also with Hungary, Croatia, Transylvania, and Turkey. It is the seat of two great fairs, each of which lasts for three weeks. Gratz was taken by the French in 1809, after a siege of seven days. Pop. (1851) 55,421.

GRAUDENS, a town of Prussia, province of West Prussia, and government of Marienwerder, on the right bank of the Vistula, here crossed by a bridge of boats 2700 feet long, 18 miles S.S.W. of Marienwerder. It is surrounded by a wall, and is farther protected by a strong fortress which commands the Vistula. It has a gymnasium, training seminary, house of correction, and an establishment for the reformation of juvenile offenders; also breweries, woollen cloth and tobacco factories, and some trade in corn. Pop. (1849) 7639, besides 2454 military.

GRAUNT, JOHN, the author of *Observations on the Bills of Mortality*, and the founder of Political Arithmetic, was born at London, April 24, 1620. At an early age he was apprenticed to a haberdasher in the city; and when he entered into business on his own account, he gained the esteem and confidence of his fellow citizens, passed with reputation through all the offices of his ward, and was first captain and then major of the trained bands. It is not known at what precise time he first began to collect and digest the Bills of Mortality; but it appears, from his own statement, that he had directed his attention to the subject several years before he had any design of publishing the discoveries which rewarded his researches. His book entitled *Observations on the Bills of Mortality* was published in 1661, 4to, and met with so favourable a reception that a second edition was called for the succeeding year, and others followed. Immediately after its publication, Louis XIV., by a royal ordonnance, provided that a more exact register of births and burials should be kept in Paris; and Charles II. conceived so high an opinion of his abilities, that, at the institution of the Royal Society, he recommended Graunt to the choice of the members, with this additional charge, that if they found any more such tradesmen they should be sure to admit them. Graunt appears to have changed his religion, and become Roman Catholic, some time before his death, which took place on the 18th of April 1674. He left his papers in charge of Sir William Petty, who had all along befriended him, and who took care to adjust and insert them in a fifth edition of his work, published in 1676, 8vo. The observations of Graunt may be considered as having formed the elements of that useful science afterwards styled Political Arithmetic, which, therefore, he is entitled to the honour of having founded; and whatever merit may be ascribed to Sir William Petty, Mr Daniel King, Dr Davenant, and others, there can be no doubt that the *Observations on the Bills of Mortality* served as the model, if not as the basis, of all their investigations. (J. B—E.)

GRAVE, in *Grammar*, a species of accent opposed to acute, and expressed thus (`). It marks that the voice is to be depressed, and the syllable it is placed over is to be pronounced in a low deep tone.

Grave (Sax. *græf*), a tomb or sepulchre. See Burial.

GRAVELINES, a strongly fortified seaport town of France, department of Le Nord, and arrondissement of Dunkerque, on the Aa, near its mouth, in the English Channel. It is chiefly known for its fortifications, which are of great strength, having been constructed by Vauban; and, being in a low marshy situation, protected from the sea by *dunes* or sandhills, the surrounding country may be laid under water at pleasure. The inhabitants are chiefly engaged in the cod, mackerel, and herring fisheries. Pop. 5582.

GRAVESANDE, William Jacob, a distinguished Dutch geometer and natural philosopher, was descended of an ancient and honourable family, and born at Bois-le-duc, in Holland, Sept. 27, 1688. The name of his family was properly Storm van s'Gravesande. He studied the civil law at Leyden; but the mathematics were his favourite pursuit. When he had taken his doctor's degree in 1707, he settled at the Hague, where he practised at the bar, and cultivated the acquaintance of learned men. In May 1713 he, with some other young men distinguished for their acquirements, organized a review entitled *Le Journal Littéraire*, which was continued without interruption till 1722. In 1715 s'Gravesande, in the capacity of secretary of legation, accompanied the deputies of the states-general sent to London to compliment George I. on his accession to the throne, and there, through the influence of Dr Burnet, Bishop of Salisbury, was admitted a member of the Royal Society. He returned the following year to the Hague, and in 1715 was appointed ordinary professor of mathematics and astronomy in the academy of Leyden. During the vacations of 1721 and 1722, s'Gravesande made two journeys to Cassel to visit the landgrave of Hesse, a prince who showed an enlightened taste for experimental philosophy, and generously furthered its advancement. In 1724 he resigned the rectorship of the academy, to which he had previously been promoted, and on this occasion pronounced a discourse *De Evidentia*, which has been prefixed to the third edition of his *Elements of Physics*. In 1730 he added to his ordinary course civil and military architecture, which he taught in Dutch; and in 1734 he was also appointed to teach philosophy, including logic, metaphysics, and ethics. S'Gravesande died Feb. 28, 1742, at the age of fifty-five. His principal works are: *Essai de Perspective*, Hague, 1711; *Physices Elementa Mathematica, experimentis confirmata, sive Introductio ad Philosophiam Newtonianam*, Hague, 2 vols. 4to, 1720–1742; *Philosophiæ Newtonianæ Institutiones in usus academicos*, an abridgement of the preceding, Leyden, 1723, 1728, and 1744; *Matheseos Universalis Elementa, quibus accedunt, specimen commentarii in Arithmeticam universalem Newtoni et de determinanda forma seriei infinitæ adsumtæ Nova Regula*, Leyden, 1727, in 8vo; *Introductio ad Philosophiam, Metaphysicam et Logicam continens*, Leyden, 1736, 1737. In the *Dictionnaire Historique* of Prosper Marchand may be found a detailed biography of s'Gravesande by Allemand, the editor of the work, who was intimately connected with s'Gravesande and his family. There is also an elaborate life of him in the *Biog. Univers.*, by De Gerando.

GRAVESEND, a municipal borough, river port, and market-town of England, county of Kent, on the right bank of the Thames, 22 miles below London, with which it is connected by railway. Gravesend is chiefly indebted for its prosperity to its intercourse with London; and since the establishment of steamboat and railway communication with that metropolis, it has been gradually increasing in size and importance. It occupies a pleasant and healthy situation, with good accommodation for bathing; and from the heights above the town, especially that called Windmill Hill, extended views of the river with its windings and shipping are obtained. During the summer season it is much resorted to by the middle classes of London, many of whom have houses here to which they come daily or weekly at the close of business. The crowds of visitors that come here on Sunday in fine weather are very great. The town occupies an acclivity rising from the river; the older and lower part of it is irregularly built, with narrow and inconvenient streets, but the upper and newer portion is well and regularly built, and has several handsome streets, squares, and terraces. The town-hall is a neat and conspicuous Doric edifice, erected in 1836. The church, which stands near the centre of the town is a neat brick building. It has several other churches and chapels, a free grammar-school, literary institution, market-house, custom-house, theatre, concert-room, bazaars, baths, &c. It has several piers, two of which, the town-pier and the terrace-pier, are very handsome and convenient structures, mostly of iron. East of the town is a battery, nearly facing Tilbury Fort on the Essex side. Gravesend is the boundary of the port of London. In the vicinity are extensive market gardens. The borough is governed by a mayor, 6 aldermen, and 18 councillors. It includes the two parishes of Gravesend and Milton, and extends along the river for a mile and a-half, and two miles inland in the southern part. Pop. (1851) 16,633.

GRAVINA, Giovanni Vincenzo, one of the most distinguished men of letters the kingdom of Naples has produced, was born at Rogiano, a small town near Cosenza, in Calabria-Ulteriore, Jan. 20, 1664. His parents, who, by their station and their fortune, held the first rank in the place, neglected nothing to promote his early education; but the precocity of mind, the vivacity of imagination, and the ardour to instruct himself evinced by their son, soon made them sensible that he required other cares at their hands, and needed to be restrained rather than stimulated. Gregorio Caloprese, his uncle, after having cultivated, with success, at Naples, poetry and philosophy, had retired to his native place, Scalea, a maritime city in that part of Calabria. The education of a nephew, who inspired so high hopes, appeared to him an agreeable task, and he willingly undertook it. As the relations of Gravino had destined him for the profession of the law, the time was now approaching when it would be necessary to make jurisprudence a serious study; but for that science he had conceived an aversion which appeared to be insurmountable. But his prejudices at length vanished; he applied himself vigorously to the study of the civil and canon law, and at the same time extended his knowledge of theology by an attentive perusal of the works of the Fathers. Gravina had long desired to visit Rome; but his uncle, Caloprese, who still superintended his education, opposed his wish until he should have completed his course of study. When this was accomplished, he repaired to the ancient capital of the world in 1689. In 1691, he published, under the suppostitious name of Priscus Censorinus, a dialogue, entitled *De corrupta Morali Doctrina*, Naples, 4to, the object of which was to prove that the corrupters of morals do more injury to the church than the boldest heresiarchs. Gravina was then only twenty-six years of age. But the eloquence of the style and the solidity of the reasoning ensured the success of the book, which, at the same time, excited lively dissatisfaction amongst the numerous partisans of convenient doctrines and loose practice. Father Concina has inserted this dialogue almost entire in his treatise *De Incredulis*. Nor did poetry escape the contamination which had so deeply infected morals. A single writer, Alessandro Guidi, a friend of Gravina, struggled at Rome against the prevailing debasement of taste, and, at the request of Christina, queen of Sweden, had, under the Arcadian name of Erillo Cleoneo, written a comedy, entitled *Endimione*. As this piece became the object of the most virulent attacks, Gravina, under the name of Bione Crateo, undertook the defence of his friend, which he read in a literary assembly, and which was afterwards printed under the title of *Discorso sopra Endimione*, Rome, 1692. This little work, in which he laid down excellent principles, drew upon the author new adversaries, who considered it equally strange and unpardonable that Gravina should attempt to constitute himself at once the censor of morals and the reformer of taste. A jealousy, almost amounting to fury, was excited against the young Neapolitan; whilst his disposition to censure the works of others, and the confidence which he appeared to repose in his own opinions, were but little calculated to calm the spirits of his enemies. Gravina sometimes commended, but he more frequently censured, and his decisions were often expressed in contemptuous terms. This tendency made him a host of enemies. His least actions were watched in order to calumniate him, and he was assailed with the most malignant invectives. Then appeared in succession, under the name of Quintio Settano, the Arcadian *alias* of Ludovico Sergardi, sixteen satires against Philodemus, the name under which Gravina was therein designated. These satires, which were equally spirited and bitter, obtained great success, and were circulated in profusion. Gravina at first affected indifference. It is a fault of the age, said he, to take pleasure in outraging merit. But as this tranquillity did not reduce his enemies to silence, he could no longer restrain his resentment, and composed some declamations of the nature of *verrine*, and also some iambics; but he has not published these retaliatory effusions, probably because he thought them inferior to the satires of Settano. The malignity of the enemies of Gravina did not lessen the esteem which he had inspired, nor abate his zeal for useful and wholesome pursuits. He united with several other literary men who had associated together for the purpose of cultivating poetry in silence. There were only fifteen of them, but their number soon increased, and Gravina assembled them for the first time in November 1695, at a house which he had provided for the purpose on Mount Janiculum. They framed for the association a democratic constitution, and took the name of *Arcadi*, or Arcadians. On the 20th of May 1696, the *Arcadi* held a general assembly on the Palatine Hill. Gravina, after an eloquent discourse, presented the marble tablets containing the laws, which he had written for the association, with the expressions consecrated in the Roman jurisprudence. During this period Gravina had composed several dissertations, which he collected under the title of *Opuscula*, Rome, 1696, and in which are included—1. Specimen prisci Juris; 2. De Lingua Latina dialogus; 3. Epistola ad Gabrielem Reignerium à Gallum; 4. De contemptu Mortis; 5. Épistola ad Trojanum Mirabellam; and, 6. Delle Favole Antiche, which has been translated into French by Joseph Regnauld. After the death of Alexander VIII., Antonio Pignatelli, having obtained the pontifical throne, under the name of Innocent XII., wished to raise Gravina to the highest ecclesiastical honours; but the latter refused to embrace the clerical profession, as all his ambition was confined to teaching the laws, and his taste led him towards secular erudition. Nor was his ambition disappointed. In 1699 he obtained the chair of civil law, and in his opening discourse traced the history of that science; whilst, in order to make his system of instruction better known, he composed the treatise *De Instauratione Studiorum*, which he dedicated to the new pontiff. The discourse *De Sapientia*, which he delivered in 1700, also relates to the same subject. In that one which is entitled *Pro Legibus ad magnum Moschorum regem*, after speaking of the pre-eminence and dignity of the Roman laws, he considers them in reference to the influence which they were likely to have in the civilization of the states of the czar, Peter the Great. The subjects of the other dissertations of Gravina we need not indicate, as they have been collected in his works. We shall merely refer to that one on the *internal rule*, because it makes known the religious sentiments with which the mind of this great civilian was deeply imbued. In 1703, Gravina passed from the chair of civil to that of canon law. From the commencement of his career as a public instructor he had abolished the usage of scholastic argumentation; and each succeeding year brought some useful change. He thought that the only means of establishing sound doctrine was to ascend to the sources or fountain-head of the laws; and this accordingly is the object of his treatise *De repetendis Doctrinarum Fontibus*. But these little treatises, which he composed with extreme facility, did not prevent him from continuing his great work, *De Ortu et Progressu Juris Civilis*, the first book of which appeared at Naples in 1701, and the whole was completed in three books, and printed in 1713. During the period which elapsed from 1711 to 1714, Gravina completed and published several works, particularly his Discourses, his book *De Romano Imperio*, Naples, 1712, in 12mo; his tragedies, *Palamede*, *Andromede*, *Appius Claudius*, *Papinianus*, and *Servius Tullius*, Naples, 1712, in 12mo; and his treatises, *Della Ragione Poetica*, Rome, 1708; and *Della Tragedia*, Naples, 1714, in 4to. Gregorio Caloprese died at Scalea in the summer of 1714. As soon as Gravina heard of his illness, he hastened to pay his last duties to a relation to whom he lay under so many obligations. He passed nearly two years in Calabria, and it was not until 1716 that he returned to Rome, where he died on the 6th of January 1718, leaving to his mother, Anna Lombarda, the property which he possessed in Calabria, and to Metastasio all that he had acquired at Rome, excepting some legacies to his other pupils, Giuliano Pier-Santi, Lorenzo Gori, and Horazio Bianchi, all men of reputation in letters. The works of Gravina have been collected in three volumes, under the title of *Opere del Gravina*, Leipzig, 1737, in 4to, and Naples, 1756, with notes by Mascovius the editor. (J. B—E.)

GRAVINA, an episcopal city of southern Italy, kingdom of Naples, and province of Bari, on the left bank of the Gravina, 37 miles S.W. of Bari. It is surrounded by walls flanked with towers, and has a cathedral and eight other churches, a college, and several convents. Its ancient castle was, during the middle ages, one of the strongholds of the Orsini, to which family the town and neighbourhood still belong. The cattle fair held here on the 20th April is one of the most famous in the kingdom. The vicinity is celebrated for its pasturage and for its breed of horses. Pop. 11,000.

GRAVITATION, and Gravity, terms used synonymously to denote the mutual tendency which all bodies have to approach each other. See Physics.

GRAVITY, Specific, the weight of any body as determined by its relation to the weight of another body which is assumed conventionally as a standard of measurement. The standard generally adopted is that of water at a certain temperature. This subject is explained in detail under Hydrodynamics, chap. ii.

GRAY, a town of France, capital of a cognominal arrondissement, in the department of the Haute Saône, on the declivity of a hill, on the left bank of the Saône, 29 miles S.W. of Vesoul. From its situation on the Saône, it enjoys great facilities for trade, and is an entrepôt for goods passing between the south and east of France. The town is built in the form of an amphitheatre, and at a distance presents an attractive appearance, which, however, disappears on nearer inspection,—the streets being narrow, crooked, and steep. It is commanded by the ruins of an ancient castle, formerly inhabited by the Dukes of Bourgogne. It has a fine quay, a handsome bridge across the river, cavalry barracks, town-hall, exchange, theatre, several hospitals, communal college, and public library. Pop. (1851) 6703.

GRAY, THOMAS, the author of the celebrated *Elegy written in a Country Churchyard*, was born in Cornhill, London, December 26, 1716. His father, Philip Gray, an exchange broker and scrivener, was a wealthy and nominally respectable citizen, but he treated his family with brutal severity and neglect, and the poet was altogether indebted for the advantages of a learned education to the affectionate care and industry of his mother, whose maiden name was Antrobus, and who, in conjunction with a maiden sister, kept a millinery shop. A brother of Mrs Gray was assistant to the Master of Eton, and was also a fellow of Pembroke College, Cambridge. Under his protection the poet was educated at Eton, and from thence went to Peterhouse, attending college from 1734 to September 1738. At Eton he had as contemporaries Richard West, son of the Lord Chancellor of Ireland, and Horace Walpole, son of the triumphant Whig minister, Sir Robert Walpole. West died early in his 26th year, but his genius and virtues and his sorrows will for ever live in the correspondence of his friend. In the spring of 1739, Gray was invited by Horace Walpole to accompany him as travelling companion in a tour through France and Italy. They made the usual route, and Gray wrote remarks on all he saw in Florence, Rome, Naples, &c. His observations on arts and antiquities, and his sketches of foreign manners, evince his admirable taste, learning, and discrimination. Since Milton, no such accomplished English traveller had visited those classic shores. In their journey through Dauphiny, Gray's attention was strongly arrested by the wild and picturesque site of the Grande Chartreuse, surrounded by its dense forest of beech and fir, its enormous precipices, cliffs, and cascades. He visited it a second time on his return, and in the album of the mountain convent he wrote his famous Alcaic Ode. At Reggio the travellers quarrelled and parted. Walpole took the whole blame on himself. He was fond of pleasure and amusements, "intoxicated by vanity, indulgence, and the insolence of his situation as a prime minister's son"—his own confession—while Gray was studious, of a serious disposition, and independent spirit. The immediate cause of the rupture is said to have been Walpole's clandestinely opening, reading, and resealing, a letter addressed to Gray, in which he expected to find a confirmation of his suspicions that Gray had been writing unfavourably of him to some friends in England. A partial reconciliation was effected about three years afterwards by the intervention of a lady, and Walpole redeemed his youthful error by a life-long sincere admiration and respect for his friend. From Reggio Gray proceeded to Venice, and thence travelled homewards, attended by a *laquais de voyage*. He arrived in England in September 1741, having been absent about two years and a-half. His father died in November, and it was found that the poet's fortune would not enable him to prosecute the study of the law. He therefore retired to Cambridge, and fixed his residence at the university. There he continued for the remainder of his life, with the exception of about two years spent in London, when the treasures of the British Museum were thrown open. At Cambridge he had the range of noble libraries. His happiness consisted in study, and he perused with critical attention the Greek and Roman poets, philosophers, historians, and orators. Plato and the Anthologia he read and annotated with great care, as if for publication. He compiled tables of Greek chronology, added notes to Linnæus and other naturalists, wrote geographical disquisitions on Strabo; and, besides being familiar with French and Italian literature; was a zealous archæological student, and profoundly versed in architecture, botany, painting, and music. In all departments of human learning, excepting mathematics, he was a master. But it follows that one so studious, so critical, and so fastidious, could not be a voluminous writer. A few poems include all the original compositions of Gray—the quintessence, as it were, of thirty years of ceaseless study and contemplation, irradiated by bright and fitful gleams of inspiration. In 1742 Gray composed his *Ode to Spring*, his *Ode on a Distant Prospect of Eton College*, and his *Ode to Adversity*,—productions which most readers of poetry can repeat from memory. He commenced a didactic poem, *On the Alliance of Education and Government*, but wrote only about a hundred lines. Every reader must regret that this philosophical poem is but a fragment. It is in the style and measure of Dryden, of whom Gray was an ardent admirer and close student. His *Elegy written in a Country Churchyard* was completed and published in 1751. In the form of a sixpenny *brochure* it circulated rapidly, four editions being exhausted the first year. This popularity surprised the poet. He said sarcastically that it was owing entirely to the subject, and that the public would have received it as well if it had been written in prose. The solemn and affecting nature of the poem, applicable to all ranks and classes, no doubt aided its sale; it required high poetic sensibility and a cultivated taste to appreciate the rapid transitions, the figurative language, and lyrical magnificence of the odes; but the elegy went home to all hearts; while its musical harmony, originality, and pathetic train of sentiment and feeling, render it one of the most perfect of English poems. No vicissitudes of taste or fashion have affected its popularity. When the original manuscript of the poem was lately (1854) offered for sale, it brought the almost incredible sum of L.131. The two great odes of Gray, the *Progress of Poetry* and *The Bard*, were published in 1757, and were but coldly received. His name, however, stood high, and, on the death of Cibber the same year, he was offered the laureateship, which he wisely declined. He was ambitious, however, of obtaining the more congenial and dignified appointment of Professor of Modern History in the University of Cambridge, which fell vacant in 1762, and, by the advice of his friends, he made application to Lord Bute, but was unsuccessful. Lord Bute had designed it for the tutor of his son-in-law, Sir James Lowther. No one had heard of the tutor, but the Bute influence was all-prevailing. In 1765 Gray took a journey into Scotland, penetrating as far north as Dunkeld and the Pass of Killiecrankie; and his account of his tour, in letters to his friends, is replete with interest and with touches of his peculiar humour and graphic description. One other poem proceeded from his pen. In 1768 the Professorship of Modern History was again vacant, and the Duke of Grafton bestowed it upon Gray. A sum of L.400 per annum was thus added to his income; but his health was precarious—he had lost it, he said, just when he began to be easy in his circumstances. The nomination of the Duke of Grafton to the office of Chancellor of the University enabled Gray to acknowledge the favour conferred on himself. He thought it better that gratitude should sing than expectation, and he honoured his grace's installation with an ode. Such occasional productions are seldom happy; but Gray preserved his poetic dignity and select beauty of expression. He made the founders of Cambridge, as Mr Hallam has remarked, "pass before our eyes like shadows over a magic glass." When the ceremony of the installation was over, the poet-professor went on a tour to the lakes of Cumberland and Westmoreland, and few of the beauties of the lake-country, since so famous, escaped his observation. This was to be his last excursion. While at dinner one day in the college-hall he was seized with an attack of gout in his stomach, which resisted all the powers of medicine, and proved fatal in less than a week. He died on the 30th of July 1771, and was buried, according to his own desire, beside the remains of his mother at Stoke Pogeis, near Slough in Buckinghamshire, in a beautiful sequestered village churchyard that is supposed to have furnished the scene of his elegy.[1] The literary habits and personal peculiarities of Gray are familiar to us from the numerous representations and allusions of his friends. It is easy to fancy the recluse-poet sitting in his college-chambers in the old quadrangle of Pembroke Hall. His windows are ornamented with mignonette and choice flowers in China vases, but outside may be discerned some ironwork intended to be serviceable as a fire-escape, for he has a horror of fire. His furniture is neat and select; his books, rather for use than show, are disposed around him. He has a harpischord in the room. In a corner of one of the apartments is a trunk containing his deceased mother's dresses, carefully folded up and preserved. His fastidiousness, bordering upon effeminacy, is visible in his gait and manner,—in his handsome features and small well-dressed person, especially when he walks abroad and sinks the author and hard student in "the gentleman who sometimes writes for his amusement." He writes always with a crow-quill, speaks slowly and sententiously, and shuns the crew of dissonant college revellers who call him "a prig," and seek to annoy him. Long mornings of study, and nights feverish from ill-health, are spent in those chambers; he is often listless and in low spirits; yet his natural temper is not desponding, and he delights in employment. He has always something to learn or to communicate—some sally of humour or quiet stroke of satire for his friends and correspondents—some note on natural history to enter in his journal—some passage of Plato to unfold and illustrate—some golden thought of classic inspiration to inlay on his page—some bold image to tone down—some verse to retouch and harmonize. His life is on the whole innocent and happy, and a feeling of thankfulness to the Great Giver is breathed over all.

Various editions of the collected works of Gray have been published. The first, including memoirs of his life and his correspondence, edited by his friend, the Rev. W. Mason, appeared in 1775. It has been often reprinted, and forms the groundwork of the editions by Mathias (1814) and Mitford (1816). Mr Mitford, in 1843, published Gray's correspondence with the Rev. Norton Nicholls; and in 1854 another collection of Gray's letters was published, edited also by Mr Mitford. Every scrap of the poet's MSS. is eagerly sought after, and every year seems to add to his popularity as a poet and letter-writer. (R. C—S.)

GRAYWACKE. See GREYWACKE.

GRAZALEMA (anciently *Lacidulermium*), a secular town of Spain, province and bishopric of Malaga, department of Ronda. It contains about 12,000 of a population, 5000 of whom are engaged in manufactures. This includes the suburbs of Gaidobar and Benamahoma; and it has 3 hermitages, 1 parish church, 1 convent of the barefooted Carmelites, &c. The name of this town is of Arabic origin; and there are still found in it inscriptions and other Roman antiquities. It stands on the great road from Ronda to Cadiz. The neighbouring sierra of the same name is of great extent, and occupied by sheep and immense herds of swine, in which a large traffic is carried on in the town, as well as with Seville and Cadiz. The manufactures consist chiefly of woollen and linen, flannel, leather, and soap; thread, dyeworks, carding-wool, &c. The export trade consists of the animal produce of the sierras, and articles manufactured in the town.

GREAT SALT LAKE, in the Utah territory of North America, lies on the margin of the Great Basin, between W. Long. 112. and 113., and under N. Lat. 41. See UTAH.

GREAVES (Fr. *grève*), a kind of armour for the legs, originally of leather, quilted linen, &c., and afterwards of steel. This kind of defence for the legs was used both by the Greeks and Romans, by the former of whom they were called *κνημίδες*, by the latter *ocreæ*. Greaves were made of various kinds of metal.

GREAVES, JOHN, an eminent mathematician and antiquary, was the eldest son of John Greaves, rector of Colemore, near Alresford in Hampshire, and born in 1602. He went to Baliol College, Oxford, in 1617; was chosen fellow of Merton in 1624; and, six years later, professor of geometry in Gresham College, London. After travelling in Europe, he visited the East in 1637, and collected a considerable number of Arabic, Persic, and Greek manuscripts, of which he well knew the value, as he was a thorough master of these languages. He also collected for Archbishop Laud many oriental gems and coins. He made a more accurate survey of the pyramids of Egypt than any traveller who had preceded him, and afterwards digested his observations in a work on that subject. On his return from the East, he visited a second time several parts of Italy; and during his stay at Rome instituted inquiries into the ancient weights and measures. Soon after his return he was appointed to the Savilian professorship of astronomy at Oxford, but was deprived of his Gresham professorship, the duties of which he had wholly neglected. In 1648 he lost his fellowship as well as his chair on account of his adherence to the royalist party. But his private fortune more than sufficed for all his wants till his death in 1652. Besides his papers in the Philosophical Transactions, the works of Greaves printed separately are, *Pyramidographia*, or *a description of the Pyramids in Egypt*, London, 1646, in 8vo; *A Discourse of the Roman Foot and Denarius*, ibid. 1649, in 4to; *Elementa Linguæ Persicæ*, ibid. 1649, in 4to; *Epochæ celebriores Astronomis, Historicis, Chronologis Chataiorum, Syro-Græcorum, Arabum, Persarum, &c. usitatæ, ex traditione Ulug Beig*, Arab. et Lat. London, 1650, in 4to; *Chorasmiæ et Mawarnalnabræ, hoc est, Regionum extra fluvium Oxum, descriptio*, ibid. 1650; *Astronomicæ quædam, ex traditione Shah Cholgii Persæ, una cum hypothesibus Planetarum*, ibid. 1652, in 4to. In 1737 Dr Birch published the Miscellaneous Works of Greaves, in two vols. 8vo, containing some of those above mentioned, with additions, and a biographical notice of the author.

---

[1] A claim has been put up for the churchyard of Granchester, about two miles from Cambridge, the great bell of St Mary's serving for the "curfew." But Stoke Pogeis is more likely to have been the spot, if any individual locality were indicated. The poet often visited the village, his aunt and mother residing there, and his aunt was interred in the churchyard of the place. Gray's epitaph on his mother is characterized not only by the tenderness with which he always regarded her memory, but by his style and cast of thought. It runs thus:—"Beside her friend and sister here sleep the remains of Dorothy Gray, widow, the careful tender mother of many children, one of whom alone had the misfortune to survive her. She died March 11, 1753, aged 72." She had lived to read the *Elegy*, which was perhaps an ample recompense for her maternal cares and affection. Mrs Gray's will commences in a similar touching strain:—"In the name of God, amen. This is the last will and desire of Dorothy Gray to her son Thomas Gray." [Cunningham's edit. of *Johnson's Lives*.] They were all in all to each other. The father's cruelty and neglect, their straitened circumstances, the sacrifices made by the mother to maintain her son at the university, her pride in the talents and conduct of that son, and the increasing gratitude and affection of the latter, nursed in his scholastic and cloistered solitude—these form an affecting but noble record in the history of genius.

GREECE.

Introductory observations.

GREECE and its inhabitants, after a long period of oblivion, have latterly become objects of general interest to the more enlightened nations of Europe. It was singular, indeed, that whilst classical scholars were immersed in the study of its poets, orators, and historians, the country that gave birth to so many literary treasures, though neither distant nor inaccessible, seemed to have been completely forgotten. The learned contented themselves with supposing that the modern country was inhabited by rude and unknown tribes, governed by fanatical Turks, whose barbarous rule exposed travellers to continual insults and pillage, and had swept away all traces and memorials of the ancient glory of Greece. Besides, the country was not known to be distinguished by its natural beauties; and being confounded with the torpid mass of the Ottoman empire, its political importance was reduced to nothing. Till the commencement of the present century the only intelligible accounts we had of the country were drawn from Strabo and Pausanias. The inquiries of Spon and Wheler, Le Roy, and Stuart, which brought some of its precious antiquities to light, were chiefly addressed to artists and scholars. Chandler's *Travels* were not much better adapted for general use. But the work which, more than any other, contributed to render all subjects connected with Greece and its antiquities popular, was the *Travels of Anacharsis*. Previous to the appearance of this work, however, various circumstances had contributed to bring the Greeks more conspicuously forward on the theatre of European affairs. While the general diffusion of education was increasing the number of those who felt an interest in classical subjects, the rise of the power of Russia, the connection she endeavoured to form with the Greeks, and her projects against Turkey, held out a probability that Greece might speedily regain some share of political importance. The Greeks themselves, by the desperate efforts they made in 1770, and again in 1790, gave a proof to the world, that their existence as a people, and their national feelings, had survived those destructive revolutions which were supposed to have overwhelmed them. When the political enthusiasm created by the French Revolution made the most gigantic plans of political change appear easy, the emancipation of this long neglected country from the Turkish yoke was looked to as one of the most certain and gratifying triumphs of the new principles. Before the interest arising from this state of things had expired, circumstances of a different kind directed public attention more immediately to Greece. The host of English travellers who had been accustomed to roam over the Continent, shut out from their usual routes by the arms of France, were forced into less frequented tracts, and numbers of them visited Greece. By these, and by a few individuals from other parts of Europe, a great part of the country was explored, and a great mass of information given to the public. Its topography and statistics are now better known than those of many of the nearer and more accessible parts of Europe; the classical interest of the country has been augmented by vivid descriptions of its monuments and its scenery; and the stirring events of the revolution completed in 1832 have greatly strengthened its claims to the attention and the sympathies of western Europe. It is now found that the modern Greeks, instead of being the mixed progeny of obscure and barbarous tribes, possess a respectable degree of civilization, and great capacities of improvement; that they have preserved the features and national character of their ancestors with surprising distinctness; and that their dialect does not deviate much farther from the language of Plato and Demosthenes, than that of Chaucer does from the English of the present day. Independently, too, of its other attractions, Greece surpasses Italy, and perhaps every other country in the world, in the beauty of its scenery. Its antiquities are not, like those of the latter country, accumulated chiefly upon a single spot. They are scattered over a wide surface, associated with a variety of scenery, and present memorials of many separate communities, distinguished by differences of character, habits, and civilization. Its monuments, compared with those of Rome, breathe a purer taste, a finer moral spirit, and bespeak a sublimer genius; they tell of brighter and better times, of characters and actions more surprising, generous, and romantic. Some of them transport the mind back to those remote times where truth and fable are blended,—to those delightful fictions which bear the impress of the genius of the people more distinctly than the real events of their history. No country, in short, presents greater attractions to a well-informed traveller.

Name.

In this article we shall first describe Greece in its full extent, according to the boundaries recognised in ancient times by the Greeks and Romans. We shall then give a brief sketch of the history of the late revolution; and conclude by a statistical view of the new state, which forms only a portion of ancient Greece.

The original name of the Grecian Peninsula was Hellas—a term at first confined to a small town and district in the south of Thessaly, whose inhabitants, the Hellenes, gradually overran the whole of Greece. As they extended their conquests, they gave the name of their mother country to all the places that fell under their dominion. Even their distant colonies in Italy, Sicily, and Africa, were looked upon by them as integral parts of Hellas equally with the capital cities of Greece Proper or the Peloponnesus. In a more restricted sense the term was applied to the country stretching southwards from the River Peneus and the Ambracian Gulf to the Isthmus of Corinth. The part of Epirus, however, that fell geographically within this distribution, was not regarded as forming part of Hellas, though Herodotus and others maintained that it did. The Peloponnesus, though inhabited by Hellenes, was not, strictly speaking, comprised within Greece Proper. At a later period, however, not only the Peloponnesus, but Macedonia and part of Illyria, were included in the general term. It is not known why the Romans called the country by the name of Græcia instead of adopting the term in common use among the Greeks themselves. The name *Græcia* is first used by Aristotle. After the country passed by conquest under the Roman yoke, the conquerors reduced it to a province and called it by the name of Achaia. As the various states of Greece are all discussed under their respective heads (See ATTICA, BŒOTIA, &c., &c.), we shall in the present article take the appellation in its most extensive sense, and so follow what may be considered the natural limits of the country; because the territories included within these limits are associated by certain political relations; and because many of the most interesting subjects of inquiry and discussion relating to the ancient, and still more to the modern state of Greece, connect themselves most naturally with this arrangement.

Extent.

The continent of Greece, including Albania and Mace-

---

[1] Cellarii *Geog. Antiq.*, lib. ii., cap. 13; Strabo, lib. viii.; Potter's *Antiq.* b. i., chap. 16.

donia, is nearly shut in on the north by a chain of mountains known anciently by the names of Rhodope, Scomius, and Orbelus;[1] it is bounded on the west by the Adriatic and Ionian Seas, on the south by the Mediterranean, and on the east by the Ægean Sea, or Archipelago. It extends from 36. 10. to 42. 40. of north latitude; and from 19. 45. to 24. 40. of east longitude from London. Its length, from Cape Matapan to Mount Orbelus, or Argentaro, is 450 English miles; its greatest breadth, from Durazzo to Cavale, at the foot of Mount Pangœus (a branch of Rhodope), 235 miles; and it embraces an area of 57,750 square miles, exclusive of all its islands except Eubœa. But, as our ideas of the extent of the country have always a reference to those ancient states which comprised but very minute portions of its surface, it is necessary that its dimensions should be described more in detail.

Ancient limits and divisions.

The country recognised as Greece before the rise of the Macedonian power, comprehended the Morea or Peloponnesus, Attica, Eubœa, Bœotia, Phocis, Doris, Ætolia, Acarnania, Thessály, and Magnesia; and even several of the states included within these limits had little or no share in those splendid actions which have shed so much glory over the country. The surface of Peloponnesus, which included seven different states, is about 9000 English square miles; that of the countries just named, without the peninsula, including Eubœa, is 14,800; and both together amount to 23,800 square miles—an extent of surface not exceeding two-fifths of England, or one-fifth of the British isles. If to this we add 16,000 square miles for Albania or Epirus (including the basin of the Drino), 18,000 for Macedonia, and 1000 for the Cyclades, the whole surface of Greece and its islands will be 58,800 square miles, which is almost exactly the area of England. While Greece preserved its independence, however, all these territories were never united into one body politic, nor was their confederated force ever applied to the prosecution of any common enterprise. The communities whose warlike achievements and brilliant career in arts and philosophy raised the Grecian name so high, occupied but very minute portions of the country; as the following table, deduced from measurements, will show:—

	Eng. Sq. Miles.
Attica, including Megaris and Salamis, but not Eubœa	1190
Bœotia	1530
Laconia (without Messenia)	1720
Achaia (the twelve cities with their territories)	1140

These states, therefore, were in general about equal in extent to middle-sized English counties. None of them was so large as Norfolk or Devonshire; and the two adjoining counties of York and Lancaster were nearly equal to the whole seven states of the ancient Peloponnesus. Attica, indeed, besides possessing at one period Eubœa, had many colonies in the Cyclades, Thrace, and other parts; and Sparta held Messenia long in subjection; but, in great struggles, these colonies and dependencies often shook off their allegiance, and the parent state was obliged to rely on its own resources. Such was the energy of these small communities, that Attica, which scarcely supports, at present, a population of 50,000 souls, sent out sometimes colonies of 10,000 men at once (Diod. Sic. lib. ii.); and Sparta furnished 50,000 soldiers to fight the Persians at Platæa. The territories of Corinth, when she formed a separate state, were much smaller than any of these; her wealth and power depending chiefly on commerce.

Gulfs and mountains.

Greece forms a long and rather narrow peninsula, singularly indented on three sides by arms of the sea, and having a greater proportion of its surface occupied by mountains than any other country in Europe of equal extent, except Switzerland. It has been justly observed, that those physical features which distinguish Europe from the other quarters of the world belong in a peculiar manner to Greece, and distinguish it in the same proportion from the other parts of Europe. Of these arms of the sea, the most considerable are the Gulfs of Contessa, Salonica, Volo, Ægina, and Nauplia, on the east; those of Kolokythia and Coron on the south; and those of Lepanto and Arta on the west. Of the mountains, the first in order are those which pass along the northern frontier. Mount Argentaro, the ancient Orbelus, placed at the northern extremity of Greece, near the forty-third degree of latitude, may be considered as the centre of the whole system of mountains in European Turkey. From this nucleus an elevated chain, bearing the names of Scomius and Rhodope anciently, passes south-eastward, and sends off branches on both sides, one of which, Pangeus, advances southward to the Ægean Sea, nearly opposite to the Isle of Thasus, and shuts in Greece on the east. From the same central nucleus another great chain passes south and south-eastward, under the ancient names of Scardus, Pindus, Cithæron, and Parnes, and terminates at Cape Colonna, the southmost point of Attica. This chain, which includes the celebrated mountains of Parnassus and Helicon, divides the northern continent of Greece into two parts of nearly equal breadth, and gives birth to all the most considerable rivers, which flow off on its opposite sides, but in no instance cross it. On the east side, besides many small lateral ridges, it sends off two principal branches, which enclose Thessaly on the north and south; these are the Cambunian Mountains, which, connecting the central ridge of Pindus with the lofty group of Olympus, separate Macedonia from Thessaly; and Mount Œta, which, running eastward to the Maliac Gulf, forms, at its termination, the famed pass of Thermopylæ. Mount Othrys, a little farther north, may be considered as a subordinate chain to Œta. Mount Olympus is separated only by a narrow ravine from Ossa and Pelion, which enclose Thessaly on the east. On the western side of the central chain, the whole country to the Ionian Sea, northward of the Gulf of Arta, is covered by a series of ridges, not running off laterally, but disposed in lines nearly parallel to the central chain, and separated by deep valleys. One of these ridges, nearest the coast, and terminating in a promontory, in latitude 40. 30., was known anciently by the name of Acroceraunus; another farther north, and more inland, was Mount Tomarus. A long and narrow ridge occupies the Island of Eubœa, and is evidently continued in the outermost chain of islands included under the name of the Cyclades. Another chain of these islands may be considered as a prolongation of the great central ridge from the promontory of Sunium or Colonna.

The mountains in the Morea or Peloponnesus, which are as numerous as in the north of Greece, present rather a singular configuration. A long ridge, bent into a circular form, encloses the central plateau or basin of Arcadia; and five spurs, or subordinate ridges, run off from the different sides of this circular chain to the five prominent points of the peninsula.

---

[1] Throughout this article we use the ancient or the modern names, according as either happen to be better known than the other. In general, the ancient divisions of the country, being more minute and more accurately defined than the modern, serve better for the purposes of description. The greater number of modern travellers have felt it necessary to adopt this practice.

Elevation of mountains. The elevation of some of the Grecian mountains has been estimated, but not accurately measured. Mount Orbelus, the northern boundary of the country, has its summit covered with snow all the year,[1] and must therefore exceed 8000 feet in height; but none of the other mountains seems to reach the circle of perpetual congelation. The elevation of the great central chain of Pindus is loosely estimated by Dr Holland at 7000 feet.[2] That of Olympus, one of the loftiest summits in Greece, was computed by the ancient philosopher Xenagoras to be ten stadia and a plethrum, an elevation not materially different from that of 1017 toises, or 6500 feet, assigned to it by Bernoulli. The famed Parnassus seems to be considered by Dr Clarke and Dr Holland as rising above most of the other Grecian mountains; but as its summit is destitute of snow during a part of the year, its height cannot exceed 9500 feet, and is probably much less. This mountain is still called Parnassu by the peasants residing on it, but in the low country of Livadia it bears the name of Lakura.[3] The celebrated Athos, which is now the seat of twenty-two monasteries, rises to the height of 713 toises, or 4350 feet. (Walpole, p. 204.) Several of the Albanian mountains are estimated by Dr Holland to be from 3000 to 4000 feet high. The mean height of the mountains of the Morea is estimated at 1200 feet; on the west side they attain a height of from 3000 to 4500 feet; Mount Cyllene rises to the height of 4500 feet, and Mount Oleno to 6000; Mount Taygetus, in its range from Cape Matapan to Arcadia, varies from 3000 to 7200 feet. The plain of Tripolizza, in Arcadia, is about 2000 feet above the sea, and the insulated rock of the Acro-Corinthus about 1900. (Boblaye, *Annales des Sciences Naturelles*, Feb. 1831.)

Geology. A great part of the surface of Greece is occupied by a formation of compact limestone, of a whitish or bluish grey colour, approaching at times to the nature of chalk. It forms in some places long sharp continuous ridges, in others round or craggy summits, and it presents strata highly inclined. It contains a few organic remains, with many flint nodules, and some beds of gypsum on the western side; and occasionally masses or beds of a calcareous conglomerate. The Acropolis of Athens consists of the last-mentioned rock. The compact limestone, which forms the entire mass of Parnassus and Helicon, rests on mica slate near Athens. The hills of Attica consist generally of primitive limestone; and the same species of rock, with clay slate, serpentine, sienite, porphyry, abound in Negropont, the central parts of Pindus, Olympus, and Athos, and all round the Gulf of Salonica. Farther north, in Mounts Scomius and Rhodope, granite and gneiss are found. In general, primitive rocks are most abundant on the east side of Greece, and the secondary on the west. Tertiary deposits are found in Elis, Laconia, and Argolis; and trachytes and other igneous rocks exist in Ægina, Milo, Santorin, and on the continent at Methana in Argolis. M. Boblaye states that four, and in some cases five, successive terraces of shingle are seen at many parts on the shores of the Morea, each of which had once formed the sea beach, indicating that the land had been elevated by a corresponding number of sudden movements upwards. (Boblaye, *Annales des Sciences Naturelles*, Feb. 1831; Holland's *Travels*, p. 89, 319, &c.) It is to the peculiar constitution of the great limestone formation that Greece owes those physical features which so remarkably distinguish the country; the numerous caverns, fountains, subterraneous river courses, hot springs, and gaseous exhalations, which gave birth to so many of the popular superstitions of the ancients.

Rivers. The rivers of Greece, flowing within a narrow territory, are much inferior in size even to the larger branches of the Danube. They may be fitly compared with those of Great Britain for the length of their courses and the quantity of water they convey. The classical rivers, however, which are chiefly in the south, are generally mere brooks, such as would find a place only in a county map. The largest rivers in Greece are the Axius, now the Vardar, in Macedonia; the Drinius, now the Drino, in North Albania; the Peneus, now the Salympria, in Thessaly; the Achelous, now the Aspropotamo, in Ætolia; the Alpheus, now the Roufia, and Eurotas, now Vasilipotamo, in the Morea. These and some others have permanent streams; but the greater number are mere mountain torrents, short, but rapid in their courses, and dry in summer.

General aspect. The general aspect of Greece is characterized by a very singular distribution of its mountains. These are usually neither placed in parallel chains nor in massive groups, but are so disposed as to enclose extensive tracts of land, which assume the appearance of large basins or circular hollows. The bottom of these basins consists of an alluvial plain of the richest soil, and level as the ocean, through which sometimes rise steep insulated rocks, like the summits of vast natural columns. Nature had thus marked out the country into a number of distinct districts, admirably calculated to become the seats of small communities. The plain, with its rich alluvial soil, furnished subsistence for a dense population; the insulated rock became the Acropolis or citadel of the chief town, a place of refuge in war; and the surrounding mountains were barriers against invasion. In proportion as access from without was difficult, internal communication was rapid and easy. A crowded population, dispersed over the sides and the area of this natural amphitheatre, lived as it were in the continual presence of one another. Their country, a word of undefined import in large empires, conveyed to them as distinct an idea as that of their own homes. Its whole landscape, with its trophies, temples, monuments, and fields of renown, were constantly under their eyes. Their patriotism, concentrated within this narrow sphere,—attached to visible objects by early and habitual associations,—kept alive by frequent struggles with neighbouring communities, for independence or glory, and still more by the proud sense of individual importance, inspired by their republican institutions,—was not, as in larger empires, a vague and languid feeling, but an ardent and steady passion, of which nothing in the modern world can give us an adequate idea. The same circumstances had an influence on their political condition. Conquest, which forces nations of different habits, characters, and languages, into combination, is the great parent of slavery. In such heterogeneous masses union becomes impossible. The despot, glittering in barbaric pomp, and surrounded by foreign guards, appears in his subject provinces like a being of another order, not to collect the sentiments or redress the wrongs of the people, but to silence all complaints, and enforce obedience to his own lordly will. Though hated by all his subjects, he can still employ the wealth and the physical force of one nation to trample on the rights of another, and is thus able to hold the whole in slavery. But the small Greek communities, protected by the barriers of their gulfs and mountains, escaped this evil destiny. The people, united by identity of manners and language, by common interests and continual communication, could combine with the utmost facility to resist the first encroachments of their rulers. They were able to apply freely the lights of reason to all their common concerns, to model their government according to their circumstances and their views of common interest, and to make the end for which it existed the measure of the powers bestowed upon it. The forms of government they adopted, though not contrived by absolute wisdom, were probably in principle better adapted to their situation than any other that could have been suggested. And never did the powers of the human mind display themselves with such energy and grandeur under any other system in the history of the human race.

Of the plains we have mentioned, some terminate in the ocean, and seem to owe their existence to the retiring of the waters. Such are those of Macedonia, Athens, Argos, Laconia, Messenia, and Ambracia. Others are completely surrounded by a rampart of mountains or high grounds, except at a single point where the waters have found or forced a passage. Of this description are the three remarkable valleys of Thessaly, Bœotia, and Arcadia. Each of these forcibly suggests the idea of a vast inland lake, where the waters, accumulating for a long period, had at length burst through the barrier that confined them, and left the bottom dry. There is also an analogy between these valleys and some of the inland seas of Greece, such as the Gulfs of Corinth, Arta, Volo, and the channel of Negropont, which are marine lakes completely land-locked, and communicating with the Mediterranean by a single passage, which may at one period have been closed. It may even be conceived that the Archipelago itself, at one period, was completely shut in by a barrier of high lands, of which Cerigo, Creto, Scarpanto, and Rhodes, are portions or fragments; and that its numerous isles are either the summits of mountains which then diversified its surface, or of detached rocks like those of Meteora in Thessaly, which have resisted the incessant action of the waters.

Topography.

The valley of Macedonia, which extends in a semicircle round the head of the Gulf of Salonica, is the largest and most fertile district in Greece. Its produce has been supposed to be nearly equal to that of all the rest of the country. The rivers in the lower parts, which overflow annually, render the country marshy, and subject to the malaria. It contains a considerable number of ancient remains, but they have only been partially examined. A large tumulus still marks the site of the battle of Pydna, which reduced Macedonia to a Roman province. Thessaly, separated from Macedonia by Olympus and the Cambunian Mountains, is a vast circular basin, of fifty or sixty miles diameter, enclosed on all sides by mountains, and next in fertility to Macedonia. The whole of its waters flow off by the river Peneus. The celebrated Vale of Tempe, a deep ravine, formed by precipitous cliffs six or eight hundred feet high, and separating Mount Olympus from Ossa, affords a passage for this river to the sea on the east. The vale is about five miles long, and so narrow, that the river in some parts occupies the whole breadth of its bottom; the scenery is more striking by its grandeur than its beauty. The rocks, which are of bluish-grey marble, have a shattered appearance, and, wherever the surface admits of it, are covered with trees and shrubs. Some of the ancients believed that this defile was formed by an earthquake. Were any natural convulsion to close it up, Thessaly would again be converted into a lake; and Xerxes, when he invaded Greece, threatened the Thessalians with this catastrophe if they opposed him. The rocks of Meteora, at the upper side of the Thessalian plain, are objects of a very remarkable kind. They rise from the level surface of the country near the Peneus, and cover a triangular space of two miles each way. They consist of a great collection of lofty rocks, in the various shapes of cones, pillars, rhomboids, and irregular masses, all standing detached from one another, with faces generally as perpendicular as a wall. Their height varies from one to three or four hundred feet, and the deep winding intervals between them are filled with trees and brushwood. On the summits of some of these rocks monasteries are suspended in mid air, as it were on the tops of very tall pillars. Some of the monasteries occupy the whole surface of the rock they rest on, and persons ascending to them are swung in a basket or net, and dragged up by a rope passing over a pulley. The rocks are composed of a conglomerate, consisting of fragments of granite, gneiss, and other primitive substances, disposed in horizontal strata. The narrow district on the eastern side of Mounts Ossa and Pelion is the ancient Magnesia, and is now called Zagora. At the south extremity of Thessaly lies the famed Pass of Thermopylæ, which is merely the narrow space between the flank of Mount Œta and the sea. The part of this space nearest the sea is occupied by a marsh, between which and the cliffs the breadth of firm land is still about sixty paces, as stated by Livy. The hot springs mentioned by Herodotus, the remains of the wall built by the Phoceans, and a tumulus, believed with good reason to be that of the Spartans, are all yet to be seen. The length of the pass is about five miles. The country of Phocis, which lies immediately south of the pass, is one of the most rugged in Greece, being occupied almost entirely by the branches and declivities of Mounts Œta, Parnassus, and Helicon. Bœotia is a large circular valley, enclosed by Parnassus on the west, Helicon on the south, Cithæron on the east, and a range of high lands on the north. A low ridge running north and south divides it in two. The lake Copais, which occupies the bottom of the western and larger division, and receives all its rivers, sends off its waters by subterraneous passages to the sea on the north-east. In summer this lake has the appearance of a green meadow covered with reeds. Bœotia has more than once been inundated by obstructions in these subterraneous channels. The country is very fertile, but is higher and colder than Attica. It is often covered with thick fogs, as described by the ancients; and, from the abundance of its marshes, is very subject to malaria. Attica, which adjoins to Bœotia on the east, is comparatively arid and barren, hilly rather than mountainous, but distinguished peculiarly by the dryness and elasticity of its atmosphere, and the beauty and serenity of its climate. The isthmus of Corinth, which connects Attica with the Morea, is occupied towards the north by high rocky hills, which render it strong as a military post; but in the south, where its breadth is about four miles, the surface is low, seldom exceeding a hundred and fifty feet. The remains of the ancient wall, and of the canal begun by Nero, are yet visible. The Morea consists of an elevated central plateau or valley, namely, Arcadia, and of five separate districts, formed by the exterior declivities of the mountains which surround the central plateau, and by spurs or branches which run off from these mountains. The central valley of Arcadia, so famed for its pastoral character by the ancients, is, like the inland districts of Thessaly and Bœotia, high and cold, often covered with fogs, arising from the moisture of its soil, and hence also subject to malaria. All its running waters escape by the single channel of the Alpheus; and it has sometimes suffered from partial inundations. Its scenery, in the opinion of Lord Byron, is by no means deserving of its ancient celebrity. Argolis, lying in a semicircle round the Gulf of Nauplia, embraces but a small portion of level country, which, however, is remarkably rich, but very unhealthy. The city of Argos still exists in its ancient plain, and, till ruined by the revolution, was one of the best built towns in the Morea. The ancient

Laconia, consisting of the long open valley of the Eurotas, is very thinly peopled. The ruins of Sparta, four miles south-west from the village of Mistra, are extensive, but afford no fine specimens of architecture; the spot is entirely deserted. Messenia, which lies round the head of a gulf, has a pretty large plain, of a very rich soil. Elis, on the west, and Achaia, on the north of the Morea, are in general hilly, and rather dry. In general, the west of Greece has a different physical character from the east. Ætolia, Acarnania, and Epirus (the modern Albania), present none of those circular basins so characteristic of the east and south sides of the country, except the valley surrounding the Gulf of Arta. Ætolia and Acarnania consist of long valleys open to the south, and rising into mountains in the north. Albania has the same features on a larger scale. Its mountains, which are more numerous than those of any other district of Greece, cover the country in long parallel ridges, and are separated by deep valleys, some of which open to the south, and others to the west, but none to the north. The Cyclades, and other islands in the Ægean Sea, are almost all steep and rocky.[1]

Scenery.

The mountains of Greece, which cover so large a proportion of its area, are partly wooded and partly naked, and the woods abound more on the west side than the east. The low country susceptible of tillage probably does not amount to more than two fifths of the whole surface, and of these two fifths, judging from the corn, olives, cotton, tobacco, &c. required for the population, one twelfth or fifteenth part may be actually in cultivation. It is generally bare of wood, and, from the want of enclosures, the profusion of weeds and brushwood, the thinness of the population, and the ruinous condition of the few cottages, combined with the crumbling remains of the noble structures of the ancients, has a desolate, melancholy, and deserted aspect, which harmonizes well with the fallen fortunes of the country. In the end of summer, from the excessive heat which dries up the streams, the hills and fields appear parched. In many quarters of the country, however, there are copious perennial springs, which gush out suddenly from the limestone rock. Greece combines in the highest degree every feature essential to the finest beauties of landscape, except large rivers, which are perhaps incompatible with the general character of its scenery. Travellers of taste have wanted words to describe the magnificence of the views it affords. Its mountains encircled with zones of wood, and capped with snow, though much below the Alps in absolute height, perhaps are as imposing from the suddenness of their elevation. Rich sheltered plains lie at their feet, which want nothing but an industrious population to fill the mind with images of prosperity, tranquillity, and happiness. But it is in the combination of these more common features, with so many spacious and beautiful inland bays and seas, broken by headlands, enclosed by mountains, and specked and studded with islands, in every variety of magnitude, form, and distance, that Greece surpasses every other country in Europe, and perhaps in the world. The effect of such scenery, aided by a serene sky and delicious climate, on the character of the Greeks, cannot be doubted. "Under the influence of so many sublime objects, the human mind becomes gifted as by inspiration, and is by nature filled with poetical ideas." Greece became the birth-place of taste, science, and eloquence, the chosen sanctuary of the muses, the prototype of all that is graceful, dignified, and grand, in sentiment or action. The poetry of the north, nursed amidst bleak mountains, amidst oceans covered with fogs and agitated by storms, is austere and gloomy; but the muses of Greece, awakened into life in a rich and beautiful land, amidst bright and tranquil seas, are gay, joyous, and luxuriant. You almost conceive (says Chateaubriand), as it were by intuition, why the architecture of the Parthenon has such fine proportions, why ancient sculpture is so unaffected, so simple, so tranquil, when you behold the pure sky and delicious scenery of Athens, of Corinth, and of Ionia. In this native land of the muses, nature suggests no wild deviations: she tends, on the contrary, to dispose the mind to the love of the uniform and the harmonious.[2]

Climate.

The climate of Greece seems to be distinguished from that of Spain and Italy in the corresponding latitudes, chiefly by having the characteristics of an inland region in a higher degree; that is, the extremes of summer and winter are more severe. In Attica, which has a drier atmosphere and more uniform temperature than the rest of the country, the average rain is about twenty-one or twenty-two inches, and the greatest heat, in each of the four years ending with 1807, was 104, 99, 93, 94. The greatest cold was from 28 to 32 of Fahrenheit. The mean deduced from all these extremes is 63·5. This agrees very nearly with the temperature of a spring in the isthmus of Corinth, observed by Dr Clarke to be 64, and with the temperature given in Professor Leslie's table, which is 64·4. At the southern extremity the annual temperature, according to the same authority, is 65·3, and at the northern extremity about 60. But local diversities have a greater effect than mere difference of latitude, on the distribution of the seasons. In Attica, which, being freely exposed to the sea, has in some measure an insular climate, the winter sets in about the beginning of January. About the middle of that month snow falls, but is seldom seen for more than a few days, though it lies for a month on the summits of the mountains. Gentle rains fall about the middle of February, after which spring commences; and the corn, which is a considerable height in March, is cut in May. In the beginning of March, the vines and olives bud, and the almonds are in blossom. In the great interior plains and valleys, which are girt with mountains, and cut off from the direct influence of the sea, the winters are much colder, and the summers, making allowance for the difference of height, are warmer. At Tripolizza, in Arcadia, the snow has been found eighteen inches thick in January, with the thermometer at sixteen degrees Fahrenheit; and it sometimes lies on the ground six weeks. Dr Clarke was informed, that in the winter preceding his visit, the peasants at the foot of Mount Cithæron in Bœotia were confined to their houses for several weeks by the snow. At Yanina, situated in an inland plain, 1000 or 1200 feet above the sea, the snow lies to a considerable depth in the winter, and sometimes falls as late as April. The neighbouring lake was so firmly frozen over in 1813, that it was everywhere crossed on the ice. The summits of the central chain of Pindus, and most of the Albanian mountains, are covered with snow from the beginning of November to the end of March. These various facts show that the winter in Albania, though shorter than in England, is as severe; but that the summer is a vast deal hotter, the extreme summer temperature being fifteen or eighteen degrees higher at Athens than London; while Bœotia and Thessaly are probably still hotter than Attica. Though we have no accurate data to establish a comparison between the climate of Greece and those of Spain and Italy, yet the fact of cotton being successfully cultivated, on a large scale, in Macedonia, as far north as the latitude of Rome and Valadolid, where it does not succeed in the two last countries, is a proof that the summer temperature in Greece is higher than either in Spain or Italy. The coldest weather in all parts of Greece is accompanied with a N.E. wind. The N. and N.W. winds are distinguished by their serenity and dryness. The zephyr or W. wind is famed for its balmy softness; the S.E., S., and S.W. winds are all humid, and the E. wind still retains the character of a morning breeze, as described by Aristotle. The sirocco is felt in Greece. It blows from the S.E., and produces its usual effects on the human constitution; a sense of oppression, a dull headach, with lassitude and uneasiness in the limbs. Earthquakes are very frequent in Greece, but they are seldom very destructive.[1]

Metals.

As yet little is known of the mineral resources of Greece; but, from its geological structure, we may conclude that it is, like Italy, rather poor in metals. The silver mines of Laurium, in Attica, which were extensive enough to employ 10,000 slaves, and supported the Athenian navy at one period, are now entirely abandoned. Copper also was anciently found in Attica. Ores of iron, gold, silver, lead, or alum, were wrought in Eubœa and Melos, Naxos, Siphnos, and others of the Cyclades. The gold and silver mines of Macedonia yielded Philip 1000 talents a year.

The mines and quarries of Greece might be a source of considerable wealth. The marbles of Pentelicus and Paros are still the finest in the world. The first—close, fine, glittering; the second—of a limpid transparence, with broad veins and a warm colour, giving to statues a flesh-like appearance. Not long ago there were discovered in the Archipelago quarries of rosso-antico; and in Taygetus, beds of the admirable jasper known by the name of verd-antique; but not one of these fine quarries is worked. At Marcopoulo, in Bœotia, there is a bed of lignite or coal, equivalent to $\frac{45}{100}$ths of its weight of pure carbon, but neither is this worked. At Kumi, in the island of Eubœa, there is a much better lignite, said to be equal to $\frac{2}{3}$ds of an equal weight of Newcastle coal. This mine, after paying all expenses, clears for the state 12,000 drachms a year.

Greece has several mines of argentiferous lead, especially one on the island of Zéa, where the veins run down to the sea at the bottom of a little creek where coasting vessels can touch. The ore contains about 80 per cent. of lead; and the lead, on an average, about 0·00125 of silver. These mines are not worked; but when the winter rains detach masses of ore, the municipality claims them. The produce of the emery of Naros, which is now extracted and sold by the government, may be said to be the only revenue that Greece derives from her mineral wealth. Its amount is about 400,000 drachms. One reason for the mines and quarries not being worked is the want of roads and capital.

Diseases.

There are few or no diseases peculiar to Greece. Like all the countries on the shores of the Mediterranean, it suffers greatly from malaria. This prevails chiefly in the months of August and September, and produces remittent or intermittent fevers, which attack those who reside in low situations, near the mouths of rivers, or in the neighbourhood of lakes, marshes, or rice grounds. The ancients were aware that fevers of this description affected certain districts; but, undoubtedly, the sphere of their influence has been vastly extended by the neglected state of the country. Attica, though one of the driest districts of Greece, is not entirely exempted from them. These fevers, recurring frequently, vitiate the system, and produce goitres and scrofulous complaints. Coughs, catarrhs, and apoplexies are prevalent in some districts; and elephantiasis, and leprous affections, arising probably from deficient and unwholesome nourishment, are more common than in other countries. The plague has not made its appearance since the establishment of the kingdom, and when it had previously occurred it had been imported from either Constantinople, Smyrna, or Egypt. The cholera has appeared in later years; and in 1855 it made severe ravages in Athens.

People.

It has been said that there are no longer any Greeks in Greece—that the population is altogether Albanian; but this is not correct. Notwithstanding all they had passed through, previous to the war of independence, they preserved their lineage and language to a wonderful extent. The Albanians principally inhabit Attica, Bœotia, Phocis, Argolis, with the isles of Hydra, Spezzia, Salamis, and Andros. They have also several villages in Arcadia, Achaia, and Messenia. But the wars of independence destroyed a great part of this population, and the rest is now mixed in the Greek element. In the rest of the Peloponnesus, in all the other islands, in Ætolia, Acarnania, a great part of Thessaly and Lower Macedonia, the population is exclusively Greek.

As soon as the war cry of independence was raised, many Fanariot families, who were the most educated of the Greeks, and serving the Turkish government as ambassadors in foreign missions, as learned interpreters in the Divan, and as governors in the principalities, came to assist their common country with their talents, and continued to fill the highest offices even under the government of King Otho. Such are the Morousis, the Risos, Mavrocordatos, and other distinguished families now at Athens. These speak a purified Greek, but they adopt the dress and manners of western Europe, as do also the greater part of the people in the towns.

A numerous and very different class of Greeks are the mountaineers of the northern provinces, who, finding that the diplomatic arrangements had left their part of the country in the hands of the Turks, proceeded southwards, and fixed their homes in the kingdom which had been founded by their prowess. These people who call themselves Palikars have brought with them, even into the city of Athens, many of the strange usages of their former life; and it may be said of them in common with the Mainots of the Morea, that they form the most original and characteristic portion of the Greek population. They still continue to wear the national dress—a calico shirt with a large turned-down collar, short cotton drawers, leggings fastened up to the knees, not unlike the κνημίδες of Homer's heroes, red slippers, a skirt resembling a Highland kilt, a sash, and narrow garters of coloured silk, a jacket generally of silk, and often embroidered with gold, a broad leather belt, from which are suspended an embroidered handkerchief, purse, tobacco-bag, inkstand, and arms; and to crown all, a red cap with a blue tassel. Such a dress often costs a sum equal to L.25. The dwellings of the Palikars resemble fortresses; and their servants, selected from among their old retainers, form a little garrison. They practise a ruinous hospitality, especially towards such Greeks as come from their own part of the country. Their language is mingled with Turkish words, and some of them can still speak that language.

Between the Palikars and the Fanariots, but rather resembling the latter in character and habits, are the Islanders, who are by profession mariners or traders, generally both. They wear the red cap, a short jacket, with the wide Turkish trousers instead of the kilt and leggings.

All Greeks wear the moustache but shave the beard, except in mourning, when it is allowed to grow. Whiskers are considered indicative of dandyism, and not very creditable. Few of the women are handsome; the men are almost universally so; and their great stature, slender form, oval face, long aquiline nose, large moustache, and easy gait, give them an imposing appearance. They are an exceedingly temperate people; drunkenness is a vice remarkably rare among them; their food also is spare and simple; even the richest are content with a dish of vegetables for each meal, and the poor with a handful of olives or a piece of salt fish. Very few partake of animal food more than once a week or once a fortnight, except at Easter, when every one must partake of it. All other pleasures are indulged in with similar sobriety; their passions are moderate, and insanity is almost unknown among them. They have much intelligence, aptitude, and ready wit, rather than great capacity for abstruse study and profound thought. Greek mechanics learn even a difficult trade in a few months; commercial young men rapidly acquire the command of five or six languages; students of law, medicine, and theology, likewise attain in a very short time to the knowledge necessary for their respective professions; all minds appear eager after knowledge, both as matter of pride and natural curiosity. The love of liberty and independence does not seem to have been rooted out of the national mind by centuries of subjugation; they love to command, but though they are very loyal to a good government, are apt easily to rise when their rights are infringed. As there is little love of obedience among them, so neither is there any toleration for aristocratic pretensions. They have all groaned alike under the Turkish oppression; all alike have been beaten with the same rod, all are nearly alike poor; and though in western Europe we hear of Greek counts, and even princes, such titles are not recognised in Greece itself. The counts, if of good coinage, are from the Ionian Islands, where the population received them from the Venetians; the self-styled princes are those who filled the temporary functions of hospodar or bey, under the Turkish regime. Another distinguishing characteristic of the Greeks is their ardent patriotism—a genuine legacy from their illustrious ancestors. This passion strangely blinds them as to the real importance of their country, so that one would think they deemed Greece the centre and object of all the events in Europe. But this weakness aside, it must be admitted that many of them have sacrificed all their property, which was not inconsiderable, for the liberation of their country. The public buildings of Athens have been raised by the subscriptions of individuals; most of the Greeks who live abroad bequeath their property to their national institutions.

---

[1] Holland, 47, 137, 411, 426; Hobhouse, let. 24; Pouqueville, p. 29, chap. xv.; Clarke, vi. 585, vii. 102; Arist. *Meteor.* lib. 2, c. 2.

The Greek is generally supposed to hate agriculture, and, in fact, other trades and pursuits are preferred by him. Distant voyages, hazardous speculations, and, above all, commercial bargains, are more agreeable to his disposition. But his dislike to agriculture under the Turks lay not so much in his indisposition to follow it, as in the heavy taxes and repeated exactions demanded by the pachas of his district, which left him hardly one-fourth of his products for himself.

In business the Greek is quick, intelligent, and attentive; and in his transactions with the Turks he has the celebrity of possessing keenness, amounting to swindling, inasmuch as he generally charges twice the value for the goods sold to them. But if the faithful followers of the Prophet are thus imposed upon by their more acute neighbours, it not unfrequently happens that the latter fail to get payment of half their account, and perhaps lose all.

The Albanians form about a fourth of the population of the country; and retain their foreign dialect. They are strong, patient, addicted to manual labour, and as well adapted for agriculture as the Hellenes are for commerce. The Wallachs or Blakhs on Mount Pindus, and on the borders of Thessaly and Macedonia, betray by their language their descent from the Roman colonies of Dacia, and still call themselves Romuni. They are a nomad or pastoral race, sleeping in the open air among their flocks, which are protected by ferocious dogs like those of Eumeus. In Greece a Wallach and a shepherd are synonymous.

The Maltese are numerous about Athens and Piræus; and, by a curious exception, bear a high character for honesty; whereas at Constantinople and Smyrna they are for the most part robbers and assassins. At Athens they share with the robust inhabitants of Maina the severer labours of the mason, the gardener, and the porter. The Bavarians have almost disappeared; Turks are scarcely found; and there are comparatively few settlers from other parts of Europe.

The Greeks marry young. The ceremony is a purely religious act; and divorces are not so easily obtained as in Constantinople. The pride of the Greek matron is placed in the number and beauty of her children; but though great numbers are born, comparatively few come to maturity. They die off under the influence of fever, which is a great scourge in the country.

There are very few people who have a family name, but each adds to his baptismal name either the name of his father, or some bye-name invented for himself. Thus, there are thousands of Basils, Athanasiuses, Peters, Georgeses, Nicholases, or even Aristideses, and Themistocleses. This one is Peter the son of Nicholas, or Peter the Albanian, or Peter of Nauplia, or Black Peter, or Short Peter. The duties of relationship are strictly observed; and the poor man who maintains at his own expense the widow and children of a brother is not praised as though he had done anything more than his bounden duty. The right of primogeniture is not likely ever to be known in Greece. Those who have such a strong sense of equality among compatriots will never tolerate inequality among brothers. Yet it is different with their fathers. They submit to him as to an absolute master; and this respect is shown by all classes without exception. The father has absolute command in his family, and is respected and supported to the last days of his life even by his married children. Parricide is said to be almost as little known as when Solon refused to make laws against it. There seems to be, on the whole, very much that is commendable in family life among the Greeks.

Money.

The drachm, which is the unit of the currency, is about $8\frac{1}{2}$d. of our money. It is divided into 100 equal parts called lepta. There are copper coins of 10, 5, 2, and 1 lepta, the only Greek money that circulates in the country. The silver coins of 50 and 25 lepta have been melted down or exported. Those of 1 drachm are very rare. Those of 5 drachms are now only to be found in Turkey. The gold pieces of 20 drachms, called othos, also have disappeared.

Weights and measures.

A very complete scale of weights and measures was established by the government in 1836; but the people adhere for measure of length to the pique = 27 inches. Then for weight—the principal one known, even in the capital, is the oke, a Turkish weight equal to 2 lb. 12 oz., which is divided into 400 dramia = $1\frac{3}{4}$ Eng. drams. The cantaar or quintal is generally 44 okes = 121 lbs. The kilo or quilot of corn is 22 okes, or 60 lbs. The land measure is the *strema*, equal to about one-fourth of an English acre.

Cultivated land.

It appears that not half the surface is susceptible of cultivation; and at least two-thirds of the cultivated, and four-fifths of the uncultivated soil belong to the state. One great disadvantage to agriculture is the scanty supply of running water; but the peasants are very dexterous at taking advantage of the smallest rill to irrigate their tillage.

Money rent is little known; the lands being farmed on the metayer system, according to which the landlord receives a certain proportion of the net produce—usually a third. He has frequently to furnish the seed, and sometimes the oxen for tillage, the cost of which, with high interest, is deducted from the profits before any division is made. On this system, there is little inducement for the proprietor to expend capital on improvements; still less is there for the metayer, who has no interest in the land beyond the season. Consequently, inclosure and drainage are scarcely thought of; and the stones having never been removed, lie so thick together that in some places it is scarcely credible that they can have accumulated naturally. The dwellings of the peasants are extremely poor, consisting of stones and fragments of tile and pottery held together by mud. Glass casements are rare even in provincial towns; and in the country cottages the light is most frequently admitted only by the door-way.

Productions. The arable soil of Greece is devoted chiefly to the cultivation of corn, vines, mulberry trees, and fruit trees. Wheat, rye, barley, and maize, succeed pretty well in the stony districts where the mould is but a few inches deep. Oats render but a middling crop, and the potato is quite unsuitable. But the leguminæ grow well, and rice might be raised in the wet soils. In many parts of the country cakes of maize flour form the staple article of food. (See page 32.)

At the head of all the agricultural productions for exportation are the Corinth grapes, which we corruptly call currants, and which are cultivated from the isthmus to Arcadia, along almost all the northern and western shores of the Morea. This fruit is of a violet colour, and hangs in long loose bunches. They are gathered at the same time as other grapes, dried in the sun and packed. Very few of them are used in Greece, few anywhere except in England. The consequence of this is, that the effect of raising a large crop is merely to lower the price in the London market; whereas if France, America, and Russia used plum-puddings to the same extent as the English, Greece would have had in this one article an inexhaustible source of revenue. All kinds of grapes succeed well, and the best vintage is that of the island of Santorin, where above sixty varieties are reckoned. The Russians are very fond of Santorin wine, and import L.20,000 worth yearly. The art of expressing and fermenting the juice of the grape is quite in its infancy; and unfortunately the Greeks have no wine-cellars, and very few casks. The wine is kept in skins, and rosin is put into it to keep it from spoiling. It is at first exceedingly disagreeable to the taste; but the natives prefer it to the choicest beverages of France and Spain; and even foreigners become reconciled to it with use.

Next to the vineyards as a source of revenue are the mulberry plantations. There is a demand for silk in every market in the world, and the climate of Greece affords facilities for an unlimited extension of this branch of industry. The south of the Morea generally, and all the islands of the Ægean Sea, are adapted for it, and here the house of almost every peasant is in part given up to the rearing of the worm. The spawn or eggs are nestled in the bosoms of the women; and the worms hatched in spring are abundantly supplied with the young mulberry leaves then shooting. The cocoons are placed in the sun, and the heat kills the worms. In 1836 some Greek merchants, who had resided in the silk districts of Italy, introduced Italian workmen with their families into Morea to improve the mode of winding; and a few years have greatly advanced this branch of industry and placed it on a firm and extensive basis, giving promise of a lucrative and increasing trade. Two silk-throwing manufactories have been established at Athens with great success. (For further particulars see page 32.) The *Moniteur* of Paris of 16th and 17th October 1855, pays a high compliment to the quality of the Greek silk in the Paris Exhibition, which gained the first prize.

The olive next claims attention. Being indigenous, the trees are found in a wild state in every direction, and seem only to require grafting to yield excellent fruit. Grafted olive trees are very numerous; and many of the people live all the year round on little but olives, indifferently pickled in brine. The oil is extracted in the rudest manner, after which it is either run into cisterns or jars. There is a large consumption of it in the country, nothing else being used for light, and a great deal being consumed in food and cookery; but still there remains a good quantity for exportation. Cotton succeeds well wherever it is sown, especially in the plain of Argos, and in the islands. It does not form an important item in the exports, owing to the large consumption of it in the country. Madder thrives well in the northern districts. Greek tobacco is said to be of good quality, and to have a delicious perfume. It is cultivated at little expense.

The cultivation of fruit-trees might be a profitable branch of industry. The figs of Attica have not degenerated since the olden time; the apricots are delicious; and the pomegranates, oranges, and lemons, would make a good figure in the shops of London and Paris.

First among its natural productions may be mentioned valonia, the cup of the acorn of the *Quercus Ægilops*, an oak of which considerable forests exist in the neighbourhood of Marathonisi, Cape Papa, Arcadia; also in Attica, the island of Zéa, and other places. The acorn is a powerful astringent, used in tanning and dyeing, and for this purpose is shipped for England and Italy. Another species of oak—the *Quercus coccifera*, commonly called galls—grows in great quantities on Mount Taygetus, and breeds the insect known as kermes. In the process of drying the insect assumes the appearance of a small brittle berry partly filled with powder, which, from time immemorial, has caused some to look upon it as the berry of the plant, while others considered it to be a swelling caused by the puncture of a particular kind of fly. It is used in dyeing the red Tunis caps both of the Greeks and Turks, and a good deal is exported to Tunis and Alexandria. The dried leaves of the lentisk, also, under the name of *Σχοινό φυλλον*, are used by the tanners in Greece and the Levant. Turpentine is obtained in large quantities from the pine forests of Mount Cithæron and other districts.

Notwithstanding the immense clearances made by the ravages of war and other causes, Greece contains 2,800,000 acres of forest, filled with timber trees of the best quality; yet wood is bought abroad for house and ship building, as for want of roads these forests cannot be worked. The shepherds make a practice of setting fire to the coppice woods, in order that their flocks may find some tender sprouts to crop in spring. It is not unusual in the neighbourhood of Athens to find large black patches covering half a square league; and if an explanation be required, the answer is, "Only a shepherd who has been making pasturage for his sheep."

The principal places of trade are Syra, Patras, Piræus, Kalamata, and Nauplia. The trade of Patras is chiefly import; Hydra, Spezzia, and Galaxidi, come more properly under the denomination of ship-owning ports. The exports are chiefly the articles we have enumerated, with others of minor importance; the imports are chiefly iron ware and woven fabrics; besides coffee, sugar, and spices.

The carrying trade is very considerable, especially among the islands. Some of the Greek vessels are between 600 and 700 tons register, and a good many from 300 to 400 tons; but the great majority of them are boats of 6 or 7 tons having a large hatch in midships. (See page 32.) It is customary for a ship-owner to bargain with a captain and crew, taking up a certain sum at interest, generally secured on bottomry bond; with this money a cargo is purchased on the ship's account, and the profit is divided between the vessel and the crew, the latter sharing among themselves according to their special agreements. In this way the Greeks carry on extensive speculations in corn whenever bad harvests or other circumstances present openings in the ports of Turkey, Italy, Spain, or France. Besides this, they export the various productions of Turkey, Greece, Egypt, Persia, and Southern Russia, to London, Marseilles, and Trieste. The great advantage which the

Greeks have over foreigners in prosecuting this trade is that of having relations and connections in the interior on whom they can rely for the collection of small parcels; and thus they avoid the impositions of agents and the profits of middlemen. The Greek trader despises nothing, and will gather a few bags of rags, or a ton or two of bones and horns, while he is chartering fifty vessels to load with corn and tallow. Then the same vessels supply Turkey, Persia, and Greece with the manufactures of England and Germany. The extensive Greek establishments at Manchester for purchasing, examining, and packing goods, attest the importance of this branch of commerce. They have almost quite superseded the English traders here, chiefly from their thorough knowledge of the countries to be supplied, and their readiness to execute the smallest as well as largest commissions for the shopkeepers of the East. The Greek trader slips in everywhere, neglects no business, disdains no expedient, and changes his flag as often as he finds it his interest to do so.

The Greek government does nothing for maritime trade. There is but one lighthouse on the coasts; and, notwithstanding the shipwrecks that are recorded every winter, the ministers turn a deaf ear to the appeals of the mariners. A similar neglect is shown concerning the means of internal communication. There are only seven roads, amounting in all to a length of 30 leagues, and this in a country where the state owns more than half the land, where evictions are easily effected, and where the peasants are willing to lend their hands for works of public utility. There is no highway from Athens to Sparta, or to Corinth, or to Patras, which, owing to the trade in currants, is becoming the commercial capital.

The banking and exchange operations form perhaps the most remarkable part of the commercial system. The national bank was founded at Athens in 1842, the capital being in the first instance fixed at 5,000,000 drachms. Branches have since been opened at Syra and Patras. The exchange operations throughout the country are ruled chiefly by the transactions at Athens, where bills on London, Paris, Marseilles, Trieste, &c., are negotiated with facility. The most serious hindrance to the progress of industry in Greece is the high rate of interest. The legal rate is 10 per cent. for ordinary loans, and 12 per cent. in commercial business. High as this is, most of the loans are effected at still higher rates; and the government cannot suppress the usury. From a statement inserted in the *Spectateur de l'Orient* of Athens, it appears that the bank has paid interest to the shareholders, from 1849–54, at $8\frac{1}{2}$ to $9\frac{1}{2}$ per cent. per annum; that its capital amounts now to 6,000,000 drachms, and a reserve fund of 400,000 drachms to provide against emergencies.

anufac-ures.

The manufactures of Greece are few and simple, the value of the raw material being little enhanced by the labour; yet the peasantry are entirely clothed in cotton and woollen fabrics of their own manufacture. The capotes, not only of the Greeks, but of the whole maritime population of the Mediterranean, are made of a woollen stuff, the peculiar manufacture of the Wallachs; and Kalamata is famous for a silk gauze, highly prized in the East for bed-curtains. Embroidery in gold, silver, silk, and cotton, is brought to great perfection; and marble-cutting and sculpturing have made great progress. At the Great London Exhibition of 1851, the embroidered dresses in red and gold, and in blue and silver, were highly praised. The samples of marbles were not in a condition of manufacture to demand much notice as specimens of industry. Commendatory mention is made, in the report, of lithographic stones from Messenia, samples of steatite (the French chalk of commerce), of a fine natural cement of puzzuolan, of varieties of flexible sponge, and some other objects. In the Exhibition of 1851, only four medals were given for various productions of art and manufacture from Greece; and in the Exhibition of Paris, eleven of the first class were given (five of which were for agricultural products); thirty of the second, and twenty-seven of the third.

Animals.

The Greeks call the horse Alogon, that is to say, the animal above all others. Alogon also means unreasonable, a term, it would seem, not very inappropriate, for they appear to be intractable creatures. The ass is here, as elsewhere in the East, a much less degraded animal than with us. They are tolerably swift as well as sure-footed. Oxen are scarce, and the city of Athens can only boast of five or six cows. The milk, butter, and cheese of sheep are in general use. Sheep are indeed an important part of the wealth of the country. Every family eats roast lamb at Easter.

The coasts of Greece are well provided with fish; but the people do not seem disposed to cultivate this branch of industry.

The game is excellent; the hares, snipes, and thrushes are said to have a delicious flavour. The passage of the wild ducks at certain seasons affords fine opportunities to those who live near Lake Copaïs. So the quails on their passage supply the Mainotes with food for a month; they are so heavy on their arrival that they are sometimes knocked down with sticks. Pigeons may be shot in spring and autumn during their migrations, and thrushes in March and April. The Greeks have an almost incredible tolerance for the sportsman. He wades through the barley, scrambles over the walls of the enclosures of unburnt brick at the risk of demolishing them, eats the best fruit, and nobody interferes with him except when he is seen to carry fruit away in his bag. The only enemies the sportsman has to fear are the shepherds' dogs—immense curly monsters which their masters encourage to throw themselves upon strangers. Even in towns dogs are troublesome after nightfall.

Eagles and vultures are abundant in Hymettus, Pentelicus, and most of the other mountains. A few foxes, and even jackals, are found in the Morea. The owl still inhabits the town of Athens, but it is no longer held as sacred there. In the month of April a species of hawk called the kestrel, visits the Acropolis, and rids it from all the crows which invest it. It departs, however, in October, and crows return to defile the marble of the monuments. The tortoise is common in the fields and brooks of Greece, but the people have the greatest repugnance both to the land and water animal.

Athens.

The choice of Athens as the capital of Greece proceeded on archæological rather than prudential considerations; and those who know the country express much regret that Corinth was not rather chosen, as being much more convenient for the interests of commerce, besides enjoying a more fertile soil, a more salubrious climate, and a more plentiful supply of water. Even the Piræus would have suited better than Athens, for, as has been remarked, the capital of a nation of mariners should be a seaport. When King Otho, or rather his father, decided on Athens as the headquarters of government, the once splendid city was but a village in ruins, surrounded by an arid plain. A palace was hastily erected, the court settled as it could into the neighbouring dwellings, and the officials encamped around. But houses were rapidly built; the stone costs nothing, the plaster is excellent, and the Greek masons are not unskilful. There are now 4000 houses and 32,000 inhabitants. The Turkish village which formerly surrounded the base of the Acropolis still remains, and forms a quarter of the new town called Plaka. The new quarter of Athens, where the palace, the university, the legations of England, France, Bavaria, and Russia, with other public establishments, are situated, presents a curious spectacle. The streets are not regularly laid out, nor are they carefully levelled; and a great fosse or open sewer traverses it throughout. Yet at every step are to be seen pretty houses ornamented with columns or pilasters, and standing in the midst of gardens. Even the best of these consist but of two storeys above ground and one beneath. The basement, like a cellar with us, is warm in winter, and cool in summer. Here the family take their meals. On the ground floor are the public or reception rooms, and the bedrooms above. The public buildings are few, the ministers' offices and the courts of justice are located on the first floors of houses occupied as shops or taverns below.

Government.

Greece is a constitutional monarchy. The charter guarantees to citizens equality before the law, personal and religious liberty, freedom of the press, immunity from confiscation, and education of the people at the public expense. Unfortunately for Greece, its constitution, from various causes, was never tried to its full extent; above all, the nation was not ripe for a representative government, and the king never gave to it that cordial assistance necessary to strengthen and consolidate it. Since the events of 1854, however, we learn that he has in conjunction with his ministers attempted to bring about those improvements which the advantages of the constitution enable him to do. These endeavours to improve and benefit the country are not thrown away, for the people fully appreciate them; and we may safely say that throughout Greece he is universally loved. Though religious liberty is the first article of the Greek constitution, proselytism is strictly prohibited. The highest offices of state are open to all without distinction. A Greek subject, whether he be Jew, Turk, Catholic, or other persuasion, can attain the highest position in the country by his own individual efforts.

The legislative power is exercised by the king, the senate, and the chamber of deputies collectively. The king enjoys all the privileges of a constitutional monarch; his person is sacred, and his ministers, who are seven in number, are responsible. Senators are nominated for life by the king; they must be forty years old; they receive 500 drachms (about L.18) per month. The deputies, who must be above thirty years of age, are elected from among persons who possess some property or an independent profession. They retain their places for three years, and receive 250 drachms (about L.9) per month during the session. The electors consist of all men above twenty-five years of age, who possess any kind of property, or exercise any independent profession in the district of their political residence.

The power of the king is not however really controlled either by the senators or deputies. As little are the ministers of state any check upon his sovereign will. We quote from M. About.[1]

"In fact, the power of the king is only limited by the diplomatic body. Every minister is ready to do anything for the sake of keeping his place. These men—poor, ambitious, without principles, and brought up in such a miserable school of politics—only aspire to gaining as long a time as possible their 800 drachms a month. They know that their position is precarious, that no ministry has lasted, and that the quidnuncs of the coffee-house of "Beautiful Greece" announce every morning the formation of a new cabinet. They only think, therefore, of keeping in their places, and of making the best of their temporary tenure of state affairs. Each one on coming into power takes care to surround himself with his creatures. He does so from prudence and from duty; from prudence, not to be betrayed by his subordinates; from duty, to reward the devotion of those who have served him. A minister who did not make a clean sweep in his department, and did not put devoted officials into the places of those that knew their business, would pass for a fool and an ungrateful person. He would lose the friendship of his clients, and would become the laughing-stock of his enemies. It follows that all the staff of the administration is renewed with each new ministry; that men of capacity are never formed in the offices; that the officials of all ranks, not having any certainty for the future, lay hands on all that is within their reach; that the state has no old servants, and that there is in the kingdom but one civil functionary who has been able to acquire the right to a pension. A more distant, but not less necessary consequence of such a state of things is, that the king never finds any resistance either in his ministers or in any of the other officials.[2]

"Neither did the governments which gave to Greece an absolute monarchy consider seriously enough the character of the people and the state of the country; nor did the revolutionists, who tore from the king the constitution of 1843, take into account the ignorance and barbarousness of the nation. If ever it could be said that a country was not ripe for liberty, it may be said in speaking of Greece. Not that men's minds are closed to political ideas; far from it. All Greeks, without exception, are apt to discuss public affairs—all talk of them, if not wisely, at least with a knowledge of them—all take a passionate interest in the smallest debates of the session."

In the election of representatives, political and personal passions have the greatest influence, and the government takes advantage of this to insure the election of its supporters. Sometimes intimidations and other means are used, which have, on one or two occasions, caused the loss of human life.

The judges of Greece are characterized for their independence and integrity of character. Since the government has been established we believe there is no example of their having been influenced, either by intimidation or by bribe, to commit an act contrary to their consciences. The constitution provided for the appointment for life of the judges after five years from its promulgation, but stipulated that this must first be established by a law. The reason for this was, because at that time there were few judges deeply learned in jurisprudence, and the constitution allowed five years to supply this want from the class that were then studying. Unfortunately, though the five years have long elapsed, no one has yet introduced a law to that effect, because each ministry wishes to reserve these places for their particular supporters.

For administrative purposes, the kingdom is divided into 10 nomarchies or prefectures, and into 49 eparchies or subprefectures, two of which may be administered by one subprefect. The eparchies are subdivided into demarchies or cantons; and the rural districts are administered by municipal functionaries called paredri—that is, coadjutors of the demarch. All these functionaries are nominated by the king, and salaried by the state.

For the administration of justice there is an areopagus, or supreme court, 2 courts of appeal, 3 commercial courts, 10 civil and criminal courts, 120 justice of the peace courts, with jury trials, lawyers, notaries, &c. Then there is a provisional civil code, a commercial code, a code of civil process, and a code of criminal law, which seems to secure everything that can be desired for the ends of justice. Capital punishment was introduced by the penal code in 1837, but before an executioner could be found there were 30 or 40 prisoners waiting for execution. The guillotine is the instrument used; and the horror of the scene is occasionally augmented by the struggles of the culprit to escape. The law provides that he shall walk freely and unbound to his doom; and as most of those who are thus condemned are vigorous men, brigands by profession, the struggle is sometimes fearful. The executioner, however, at length prevails, being armed with a dagger, and when the culprit is exhausted with loss of blood from its thrusts, he goes freely to suffer the last sentence of the law.

Religion.

The people, who are for the most part strongly attached to the Greek Church, have almost forgotten the religion of their king, because they look forward to the 40th article of their constitution being strictly enforced, which stipulates that the next heir or successor of King Otho shall be of the same religion as their own. Prince Leutpold, the brother next in age to Otho, declines changing his religion. A still younger brother, Prince Adalbert, consents to accept the sovereignty in his stead, and the London conference has authorized the substitution; but as he is not absolutely certain of the succession, he chooses to continue a Roman Catholic till actually put in possession of the throne; and to all appearance it will again be the fate of Greece to receive a king who is an utter stranger to them, and at heart averse to their religion.

When Greece was a province of Turkey, its religious community naturally formed part of the patriarchate of Constantinople, one of the four great divisions of the Eastern Church. The war of independence virtually freed it from this position, and the constitution of 1843 established the fact. The patriarch, however, did not recognise the independence of the church in Greece, and the result of a long negotiation between the Greek government and the patriarch was a bull or *tomos*, signed in 1850 by the patriarch and synod. It set forth that the right of uniting or separating ecclesiastical provinces had in all ages belonged to the œcumenical synods; and it granted to the Greeks the permission to separate, but not without some restriction, to the effect that difficult cases should be referred to the patriarch and his sacred college. This tomos did not satisfy either party. The Russian emperor and his partisans desired to see the Greeks kept in connection with the synod, while the friends of independence desired more perfect freedom. In 1852, the matter was brought before the Chambers, and a bill was passed to the effect that the superior ecclesiastical authority of the kingdom should reside in a permanent synod, called the Holy Synod of the Church of Greece. This synod is composed of four prelates of the kingdom, besides the metropolitan, who enjoys the right of presidency. A commissioner appointed by the king attends the sittings, not to vote, but to countersign all their acts and decisions. The functions of the synod are either internal, including the preservation of pure doctrine and worship with the maintenance of ecclesiastical discipline, and other matters purely religious; or they are external, relating to matters which involve public interests, as marriage, divorce, the excommunication of laymen, and the celebration of extraordinary religious festivals on working days. In the former, the powers of the synod are independent of the state; in the latter, it can act only in concert with the government.

Excommunication, however, is used in a different spirit from the Roman Catholic Church, namely, to influence, by the fear of God and future punishment, the consciences of those who, knowing the perpetrators of a crime, conceal, or do not reveal to the authorities, the criminal, or of those who are the possessors of stolen property. Very often this has succeeded better than the efforts of the police. It is, however, very seldom used, and the synod must first have permission from the king.

The kingdom is divided into 24 episcopal sees, of which 11 are directed by archbishops, and the remaining 13 by bishops. Every bishop is chosen by the king out of three candidates presented by the Holy Synod. He can displace him again only in conformity with the canons, and after the advice of the synod. The metropolitan receives 6000 drachms (L.212) a year; each archbishop, 5000 (L.180); and each bishop 4000 (L.145). The inferior clergy receive no salary from the state. They live chiefly by the altar, but they also levy certain portions of the harvest.

The government found the country infested with monks, and it has shut up many of their houses; but it has been impossible either to suppress or reform a convent at Janina (Turkey), containing about 200 females, who are not closely secluded, and whose morals are said to be scandalous. The religious houses are understood to be asylums of anti-national intrigue, the inmates being generally devoted to the interests of the Russian emperor, and disposed to look on King Otho as a mere heretic.

There are above 300 churches in Athens and its neighbourhood; only five or six of them are habitable, the rest are miserable sheds or ruins, yet none of them is utterly abandoned. On the day of the saint to which it is dedicated, a little lamp is lighted, a little incense burned, and a few prayers chanted. It would be deemed sacrilege to destroy even the meanest of these sanctuaries. There are no infidels or latitudinarians in Greece; no one is ashamed of punctually attending to the duties of religion. (For the doctrines and state of the Greek Church, see GREEK CHURCH.) Roman Catholics are tolerated, among whom is the king himself; but he is obliged to render public homage to the state religion five or six times a year. There are few Jews who, though they have every protection, do not seem to prosper amongst the Greeks.

The army, which was reorganized in 1843, consists now of 6 battalions of the line, 3 battalions of light infantry, 2 troops of cavalry, 3 companies of artillery, 1 company of engineers, and 1 of artillery workmen, 3 corps of gendarmerie, 1 corps of pensioners and phalanx; in all, including the administrative hospital pensioners, 952 officers, 1257 subalterns, 8237 soldiers—total 10,446.

The fleet numbers 21 vessels, principally small, except 3 steamers and some gun-boats which the government has lately ordered in England. The complement of the Greek navy is 1431 men, including 418 officers and 139 sub-officers.

Education. Greece boasts of one university, divided into the faculties of theology, philosophy, law, and medicine; a military school; a polytechnic school of arts and trades; a normal school for training elementary teachers; a school of agriculture; a seminary; seven lyceums; an extensive institute for female education; an orphan female school, called Amalion, was established last year at Athens, under the patronage of Her Majesty the Queen of Greece (who is very much beloved by the nation for her intelligence and judgment, and for the great zeal she shows for the patriotic cause); 179 Hellenic schools, in which ancient Greek is taught; and 369 communal or Romaic schools, in which strictly elementary instruction is imparted. In 1854–5 there were 643 students at the university—20 in theology, 190 law, 317 medicine, 74 philosophy, and 42 pharmacy; and there were 38,018 scholars at the various schools. The education in all, from the humblest village school to the university, is gratuitous. The effect is to draw the youth of the country in undue proportion towards the learned professions. A young man will at once enter the house of a Fanariot as a valet, and matriculate at the university as a medical student. When his studies are completed, he will ask his master's permission to attend him in future as his physician. Children and youths of all ages prosecute their studies with indefatigable eagerness; and at Athens an idle student is not to be found.

Newspapers and periodicals form the principal literature of the country, but a considerable number of books are published yearly in every branch of knowledge, either translated or original. In 1851, 188; and in 1852, 164 books were published, the greater part of which were of poetry; and though we understand few of the latter are of a first-class character, yet it shows that the Greeks aspire to gather the laurels of Parnassus once more. All the books are written by Greeks; and it may be mentioned, that out of the 164 published in 1852, 120 belong to the kingdom of Greece, 29 to the Ionian Islands, 7 to Turkey, and 8 to Vienna and London. They are a very musical people; but until lately music did not form a part of their education.

In sculpture, there is now an establishment at Athens of a talented artist, who with such splendid prototypes before him may succeed in approaching his ancestors.

In 1846 M. Salvandy, minister of public instruction in France, resolved to found at Athens a school for the promotion of literature, similar to the French Academy at Rome for the fine arts. It was decided that the members should be chosen from among young men who had obtained fellowships in history, philosophy, and literature; and that they should each spend two or three years in Athens, at the expense of the state, in a house provided for them, and prosecute the study of Greek literature. The first professors that repaired to Greece seemed at a loss what to do with themselves. Some began to learn modern Greek under an Athenian professor; others employed themselves in teaching French to the Athenians; others travelled about the country; while economisers at home, disposed to pick holes in the budget, wondered what end was gained by the 40,000 francs per annum which this academy cost the state. In 1850 a decree was passed, placing the school under the patronage of the Academy of Inscriptions and Belles-Lettres, and enjoining that each member should annually send home a paper on some question of Greek history, geography, or archæology. The institution was, however, nearly extinct, when the fortunate excavations of M. Beulé gave it a fresh impulse. There are now five young professors prosecuting with enthusiasm their researches into the archæological remains.

The kingdom of Greece has ever been pecuniarily in an embarrassed state. It was necessary for the protecting powers to enable her to negotiate a loan by becoming security for her. The sum thus raised has been squandered by the Bavarian regency, and now the revenue never meets the expenditure; so that there is little hope of the debt ever being paid. The greatest part of the taxes are paid in kind, because of the scarcity of money. The wealthy proprietors bribe or intimidate the officials; and the lesser ones are protected either by a powerful friend or by their own poverty. The ministers of finance, therefore, up to 1846, used to prepare two budgets—one indicating what sums the government ought to receive; the other, what it could dare to hope for. The year after the revolution, only a small portion of the taxes imposed were realized.

Income. The state income consists of—(1.) *Direct* taxes, including land tax, paid in kind; usufruct, or the rent paid in kind by the cultivators of the state lands; except the tax on the currants, valonia, and all kinds of fruit, which is paid in money; taxes on bees, cattle, and buildings, which are paid in money; and a tax on grants of land from the state, also payable in money. (2.) *Indirect* taxes, including customs-duties, stamp-duties, taxes on trade and professions, licenses to carry arms, consular fees, and quarantine, harbour, and navigation dues. The *public establishments*—as the mint, the mails, and the royal printing-office—yield very little return. The *national property*—consisting of mines, quarries, medicinal springs, salt-works, fisheries, forests, olive-groves, vineyards, &c.—ought to supply a considerable revenue, if the government were intelligent enough to have them worked advantageously, and strong enough to compel payment from those who work them. The state expenditure consists chiefly of the interest on the national debt, internal and foreign; the civil list; the salaries of the chambers and the expenses of the ministry; besides those of collecting taxes and customs.

Debt. The following statement of the foreign debt is from the report of M. Metaxas, audited by M. Lemaître, commissioner of the French government:—

> In 1832, France, England, and Russia, to complete the emancipation of Greece, and to assure her prosperity, supported by their guarantee a loan of sixty millions of francs. Each of the three powers guaranteed a third of the sum, that is to say, twenty millions.
>
> One part of these sixty millions was intended to indemnify the creditors of Greece, and particularly the Turkish government; the remainder was to supply the first wants of agriculture and commerce, and to form as it were a social capital for this improvised kingdom.
>
> Unfortunately, the funds were confided to the Council of Regency. The regents were irresponsible; they employed the money as they pleased, and went away without giving in any accounts. It is difficult to say which most to admire, the audacity of the regents, the simplicity of the Greeks, or the rashness of the great powers, to confide sixty millions to three individuals who had the right of squandering them.
>
> Since the year 1832, up to the 31st December 1843, the issues of the bonds for the loan amounted to:—

For the guarantee :—

	Francs.	Cents.		Drachms.	lep.
English	19,838,805	33⅓	=	22,155,977	79
Russian	19,999,573	33⅓	=	22,335,523	50
French	17,400,661	33⅓	=	19,433,058	58
	57,229,040			63,924,559	87

To be deducted :—

	Drachms.	lep.	Drachms.	lep.
Loss in the negotiation of the loan adjudged to MM. Rothschild, at 94 per cent.	3,835,473	59		
Discount paid to those that took up the loan for payment in ready money	1,176,188	10		
Commission and other expenses	1,964,251	73		
			6,986,013	42
Nett capital			56,948,546	45
Interest, sinking fund, commission, different expenses up to 31st December 1843			33,080,795	31
	Remains,		23,867,751	14
Greece contracted in Bavaria another loan, which produced, after deducting the expenses of negotiation	4,658,186	14		
Paid for interest, sinking fund, commission and expenses up to 31st December 1843	2,809,077	66		
Nett	1,849,109	00	1,849,109	00
Sums advanced by France			3,085,098	25
Sums advanced by the three Powers			2,757,028	32
Gross total of the resources of which Greece could have disposed			31,558,986	71
To be added for two heads misplaced			100,947	62
Total			31,659,934	33

Greece, or at least her government, has therefore received from foreign powers, between 1832 and 1843, a nett and clear sum of 31,659,934 drachms, 33 lepta.

Let us see how these resources have been employed :—

	Drachms.	lep.
Indemnity stipulated nominally in favour of Turkey, but in reality to the advantage of Russia, who had pecuniary demands to press against Turkey,	12,531,164	54
Reimbursement to different persons for debts anterior to the establishment of the Greek kingdom,	2,238,559	15
To which may be added, as useless expenditure, the Bavarian Regency, 1832–33	1,397,654	27
The conveyance, cost, and return of the Bavarian troops, from 1st September 1832 to 30th September 1834	4,748,050	0
	20,915,427	96
Which, deducted from	31,659,934	33
Give a remainder of	10,744,506	37

With a little assistance, Greece paid the interest of the loan of 60,000,000 frs. in the years 1841, 1842, 1843. Since then she has fallen hopelessly into arrears. She now owes to the three Powers 100,000,000 drs., which she cannot pay; besides above 200,000,000 drs. to English capitalists, which she will not pay.

As to other items of the state expenditure, the king's civil list is 1,000,000 drs., or about L.36,000 sterling; the chambers receive about 600,000 drs. a year; the seven ministers, as salary, 9600 drs.; while the departments of the army and navy expend 5,500,000 drs.; and the other five state departments, 4,500,000 drs.

It has been remarked, that if Greece were organized like the Ionian Islands, without either king, fleet, or army, 6,500,000 drs. might be realized above the annual expenditure towards liquidating her debt and improving the national property.

Antiquities.

The antiquities of Greece open so wide a field, that, in an article of this kind, we can do nothing more than allude to the various classes of objects comprised under the title. Among these we may, without much impropriety, rank many of the cities themselves, which not only exist on the very spots they anciently occupied, and bear the same names, but, deriving their most striking characters from natural objects which remain unchanged, they still present to the eye at a distance the same general aspect and outlines. With regard to the interior of the cities, also, though the august temples of the gods have disappeared, and filth and meanness meet the eye everywhere, little doubt will remain with those who have read what the ancients have left us on the subject of their private houses, and what modern travellers have told us respecting the disinterred buildings of Pompeii, that the houses at the present day—with their square inclosed courts, their projecting roofs, and dead walls, and all that is most peculiar in their plan and interior arrangements—are copies (though miserable copies) of those of the ancient Greeks; and it is probable that some of the modern dark and narrow streets of Athens come much nearer in appearance to what they were in the age of Pericles than the admirers of antiquity are willing to allow. Among the cities which occupy their ancient sites, and bear their ancient names with little alteration, may be mentioned Athens, Thebes, Livadia, Larissa, Pharsalia, Salonica, Corinth, Argos, Nauplia, Patræ; and a great number of others of less note might be added. The ancient buildings of which remains now exist belong to three different eras :—1. The very ancient structures to which the name of Cyclopean has been given, consisting of vast masses of unhewn stone, put together without cement. They are not numerous. The ruins of the citadels of Tyrins and Mycenæ, which are of this description, have remained in their present state for 3000 years, and present the most perfect specimen in existence of the military architecture of the heroic ages.[1] 2. The works of the classical ages, consisting of temples, baths, porticoes, theatres, columns, stadia, fountains, which are extremely numerous, and executed in a great variety of styles, exemplifying the infancy, progress, perfection, and decline of the arts. Of the two or three hundred temples enumerated by Pausanias—many of which were models of the most exquisite beauty and symmetry—that of Theseus at Athens was the only one tolerably entire; and it was destroyed by the Turks in 1827. Others are found in various stages of dilapidation; and the far greater part have vanished from their sites, and only left traces of their existence in their innumerable fragments of inscribed and sculptured marbles scattered over the fields, or stuck into the walls of forts, churches, and clay-built cottages. 3. A number of square towers, of a rude construction, built on the tops of hills, for military purposes, are the only memorials left by the Latin princes who ruled Greece for two or three centuries before the Mohammedan conquest. 4. Next in importance to the remains of ancient edifices we may rank the statues, bas-reliefs, and inscribed marbles; a great number of which, generally somewhat mutilated, have been brought from Greece to enrich the museums of Western Europe; and a much greater number, no doubt, lie buried under the soil. 5. Vessels of terra cotta, or ancient pottery, consisting of vases, amphoræ, lamps, &c., of exquisite workmanship, adorned with coloured designs illustrative of the arts, habits, and mythology of the ancients, and often in high preservation. The quantity of these found among the ruins of ancient cities is incredibly great. 6. Coins of gold, silver, and copper, which are great in number and variety, every considerable town having its separate coinage. 7. Amongst the most interesting remains are the tumuli, erected to commemorate great victories. These simple but expressive monuments, formed of conical mounds of earth, but long since divested of their sculptured ornaments, still mark the fields of Marathon, Leuctra, Platæa, Cheronæa, Thermopylæ, Pharsalia, and Pydna. 8. We ought also to class among the antiquities of Greece a vast number of fountains, caves, rocks, and other natural objects, which owe their interest, not to any beauty or importance they possess in themselves, but to the legends associated with them in the history and mythology of the ancient Greeks. With regard to the antiquities of Greece in general, it may be observed, that the finest, the best preserved, and the most numerous specimens of ancient art are found at Athens. Salonica, it is said, ranks next to it in this respect; but its monuments are deficient in the interest derived from classical associations. In general the southern and eastern parts of Greece, and the islands, abound most in antiquities. Albania and Ætolia contain but few, and these not of much interest.[1]

---

[1] In Sir William Gell's *Itinerary of Argolis*, a good account of these remarkable ruins is given, illustrated by excellent drawings.

Languages. There are five languages spoken in Greece at the present day:—1. The Turkish, which is in use among a few of the Turks, but the great majority speak Romaic. 2. The Bulgarian, a dialect of Sclavonic, spoken by the tribes of Bulgarians who inhabit the northern parts of Macedonia. 3. The Wallachian, in use amongst the Vlaki, who occupy the branches of Pindus and Olympus; a language of uncertain root, but containing a large mixture of Latin, and some Italian. 4. The Albanian or Skipetaric, spoken by the natives of Albania, and by some of the colonies of this people in the south of Greece. It is an unwritten tongue, and abounds in nasal sounds. Its basis is supposed to be the ancient Illyrian, with which is intermixed a large proportion of Latin, and smaller proportions of Romaic, Sclavonic, Italian, and Turkish. 5. The Romaic (Ρωμαικη) or modern Greek, spoken by all the Greeks, by most of the Turks, and by a part of the Albanians. This is the name given to the language by the Greeks, who call themselves Ρωμαιοι, or Romans, a denomination derived from the establishment of the Roman empire for so many ages at Constantinople, which they consider as the capital of Greece. The Romaic bears a much closer resemblance to the Hellenic than the Italian to the Latin. Indeed we have been informed by one of the best modern Greek scholars in Europe, that if we take the Attic as a standard, the ancient Doric differs as much from it as the present living dialect. The peculiarities which distinguish the Romaic from the ancient Greek cannot be fully explained without many details; we shall, therefore, only notice some of the most prominent. These are,—1. The disuse of the aspirates in speaking, though they are retained in writing. 2. The adoption of the first numeral εἷς *μία* ἕν, for an indefinite article, as in the French. 3. In substantives it discards the dual number, and the dative case; makes some alterations in the oblique cases; marks cases sometimes by prepositions; and often changes the Hellenic masculine and feminine into neuter. 4. The degrees of comparison are formed as of old, by adding -τερος and τατος, but sometimes by πλέον, *plus*, as in the French. 5. Diminutives are much used, as in the Italian. 6. Considerable changes and substitutions have been made in the tenses of the verbs; the infinitive and the middle voice have been suppressed, and two auxiliary verbs introduced, θέλω, *I will*, and ἔχω, *I have*. 7. The Hellenic pronouns are retained, but with many modifications. Many old Hellenic words have changed their meaning, attributives being used as substantives, and *vice versa*. The pronunciation of the Romaic deviates widely from that of the ancient Greek as taught in our schools. The B is sounded like our V, whilst the place of B is supplied by μπ. The Δ is sounded like *th* in *that*, and θ like our *th* in *think*. The vowels η, ι, υ, and the dipthongs ει, οι, υι, are all pronounced like the Italian *i*. It is said, however, that the dialects of the spoken Romaic in Greece have not so marked a difference as those of the distant provinces of France or England. The purest dialects, or those which approach nearest to the Hellenic, are found in some of the least frequented islands of the Archipelago, in the mountainous parts of Greece, at Yanina, and among the well-educated Greeks of Constantinople. The name of Romaic is going into disuse; the modern language being denominated *Neo-Hellenic*, and the ancient, for the sake of distinction, *Hellenic*.

The new Greek language has lately made immense progress, and great care is taken by every writer not only to avoid introducing any foreign idioms in the language, but also to imitate the style of their Greek prototypes. They keep with the greatest scrupulosity the ancient orthography.

The Romaic, which, before the revolution, was a mixed language, full of foreign words, and unintelligible to any one not acquainted with the Greek, the Italian, and the Turkish, is written and spoken now by the educated classes, pure, as in the ancient language. Any Greek scholars can easily understand a Greek newspaper, by impressing on his mind the above remarks on the language.

NARRATIVE OF THE GREEK REVOLUTION.

In the course of last century, the Greeks made two unsuccessful attempts to liberate themselves. The first was in 1770, during a war between Russia and the Porte. The Russians, in pursuance of a plan previously concerted, landed a small force of 2000 men at various points in the Morea. The Mainotes and other Greeks instantaneously rose in arms, and got possession of the open towns, butchering the Turks with every circumstance of cruelty. Before they had mastered any of the fortified places, however, a great force of Albanians pouring in, defeated them, and retaliated, with dreadful severity, the cruelties committed on the Turks. The inhabitants of some entire towns and villages were massacred, and the country was almost desolated. Though the Greeks acted with much vigour at the outset, it was observed that their spirits sank at the first check they received. But it is impossible to reprobate too strongly the cruelty and perfidy of the Russian government, which, by sending such an inadequate force, exposed the Greeks to certain destruction, for the sake of operating a paltry diversion in its own favour; and, at the conclusion of a peace, took no effectual means to protect them from the rage of their enemies.

In 1790, the Greeks of Suli, in Albania, rose in arms, upon an understanding that assistance was to be received from Russia. A deputation went to Petersburg to offer the crown of Greece to Prince Constantine, brother of the emperor, whom they saluted βασιλευς των Ἑλληνων. They were to collect their various troops from Suli, Livadia, Attica, and the Morea; to march through Thessaly and Macedonia, where they were to be joined by other reinforcements; and to meet the Russians at Adrianople with 300,000 men (as they gave out), after which the combined army was to proceed to Constantinople, and drive the Turks out of Europe. But in the end little was done. The Russians sent a trifling sum of money, which was chiefly embezzled by their own agents, and soon made peace, without concerning themselves about the peril into which they had brought the Greeks. The Suliotes defeated the Pasha of Yanina; and, aided by their rocks, defended themselves, performing prodigies of valour against the Albanian Turks. A squadron of twelve small vessels, which they had fitted out at Trieste, signalized itself in the Archipelago, and after spreading terror amongst the Turks, was overpowered and destroyed by a greatly superior force. This second enterprise, in short, ended like the first, without any other effect than that of exposing the Greeks to renewed outrages from the Turks. The brave tribe of the Suliotes, on whom the Greeks placed great reliance, as the best soldiers of their faith, were reduced to a remnant by Ali in 1803, after a contest of many years.

---

[1] On the subject of the Antiquities of Greece, the reader may consult the following works:—*Les Ruines des plus beaux Monumens de la Grèce*, par M. Le Roy, fol. 1758; *The Antiquities of Athens*, by Stuart and Revett, 4 vols. fol. 1762–1816; *The Ionian Antiquities*, by Chandler, Revett, and Pars, 2 vols. fol. 1769–1797; *The Unedited Antiquities of Attica*, by the Society of Dilettanti, fol. 1817; Chandler and Clarke's *Travels*, already referred to; and Mr Edward Dodwell's *Classical and Topographical Tour in Greece*, 2 vols. 4to, 1819;—and on the geographical, historical, archaiological, and statistical condition of ancient Greece, consult also M. S. R. Rangabé's, *Τὰ Ἑλληνικὰ*, edited at Athens, 1853.

Though the hopes of the Greeks were cast down for a time by this event, various causes were silently operating a change in their situation, and preparing the way for a more successful effort. Amidst all the hardships of their lot, knowledge had been steadily increasing. The influence of Russia over the Porte was visibly extending, and promised them sooner or later the means of exchanging Mahommedan for Christian rulers. But what was of more immediate importance, the establishment of Russian ports on the Black Sea, and the destruction of the French shipping by the wars of the revolution, created a trade in corn between Odessa, Marseilles, Leghorn, and Trieste, which falling into the hands of the Greeks, had raised up a class of capitalists amongst them, and given them possession of a commercial navy. From a few small barks engaged in coasting traffic, a short period saw them in possession of some hundred large well-rigged merchantmen, making long voyages. Greek houses were established at the ports mentioned, as well as at Smyrna, Salonica, and Constantinople. As patriotic feelings were universally diffused, a part of the wealth thus acquired was expended in founding schools and libraries, and the number of Greek youths sent to the universities of Western Europe was greatly increased. The ancient classic writers of the country were studied with new ardour, and lessons of freedom, magnanimity, and patriotic devotion, eagerly imbibed from their pages. Amongst the educated Greeks, those especially who had studied in France, Russia, and Germany, a more just idea was acquired of the relative weakness of the Porte, and the advantages which any people contending with it might derive from those arts and improvements, the growth of an advanced civilization, which the Turks despised. The conviction thus gained strength, that nothing more was necessary to accomplish the liberation of the Greeks, than a combined and organized effort by themselves, aided if possible by the countenance of some great Christian power. This idea gave birth to the *Hetairia*, a secret association, which is supposed to have originated about the beginning of the present century, but remained obscure and feeble till 1815. About that time Count Capo d'Istrias, a Greek by birth, who enjoyed a considerable rank in the Russian service, established a Philomuse Society, ostensibly to promote Greek literature, but really to serve as a cloak for the Hetairia. In a little time he withdrew from its apparent guidance, but without ceasing to promote its objects privately. The Hetairia had a complex and artful organization. It was divided into five orders: those of the first or lowest receiving merely a general intimation that a scheme was in contemplation to regenerate Greece; and the information communicated of the society's designs becoming more special and distinct through the other grades, to the fifth or highest, called the Grand Arch, which was composed of sixteen members, and alone possessed a full knowledge of the society's plans, the power of issuing general orders, and fixing the time and mode of execution. All the members were sworn to secrecy on their knees, at the dead of night, and bound to kill any one of their brother members who should be guilty of treachery. The grand arch had its seat at Moscow, from which it corresponded with persons in all parts of Europe. The society spread its ramifications through the southern parts of Russia, had numerous members in Odessa, Yassy, Bucharest, and in Greece Proper, and some at Vienna, Paris, and Leghorn. Most of the primates of the Morea joined it in 1819. This conspiracy had been spreading its roots through European Turkey for five years before the Ottoman government knew of its existence; and when at length apprised of the fact by an accidental circumstance, its usual apathy, and its contempt of the Greeks, prevented it from taking any precautions to avert the threatened danger. It has been said that the Hetairists had fixed upon the year 1825 for beginning the revolution; but the statement rests on no good authority. Whatever might be their intentions, the rebellion of Ali Pasha, by embarrassing the Porte, and neutralizing one who would have been a formidable enemy, presented an opportunity too favourable to be lost, and precipitated the commencement of hostilities.

In the autumn of 1820 a Turkish army advanced into Albania. Most of Ali's officers and armies having deserted his standard and joined the enemy, he shut himself up in a fortress at Yanina, after destroying the town, and prepared to stand a vigorous siege. Aware of the designs of the Hetairists, he stimulated them to take up arms, by a promise of money and assistance; and though they did not confide in it, they resolved to embrace the advantage which the position of affairs held out. The first movement was in a distant quarter. By previous concert a number of Greeks assembled at Yassy in Moldavia in the end of February 1821, and on the 6th of March Prince Ipsilanti, who held the rank of major-general in the Russian service, crossed the Pruth, and joined them. After proclaiming the independence of Greece, he left that town on the 13th, with eight hundred horsemen, proceeding towards Bucharest, but lost time foolishly on the road, and did not enter the capital of Wallachia till the 9th of April. Dissensions in the mean time broke out in his small army; and though the spirit of the people was good, and the lethargy of the Turks left him a clear space for action, his incapacity and indecision rendered him unable to improve these advantages; and a proclamation issued by the Russian consul, in which the insurrection was strongly condemned by the emperor, on whose assistance they had relied, completely disheartened the insurgents. About the end of April, a body of Turks put themselves in motion from Silistria, occupied Bucharest, and followed the insurgents northward. Some trifling skirmishes took place in the neighbourhood of Tergoivisht, rather to the disadvantage of the Greeks; and a rash and unsuccessful attack made by one of their officers at Piteshti caused a panic in the army, followed by a disastrous retreat. In this action the greater part of the Sacred Battalion, composed of Greek youths from various parts of Europe, was destroyed, after a brave resistance. Ipsilanti shortly afterwards stole away from his troops, and sought refuge within the Austrian boundary. A partisan warfare was continued a little longer. One small corps retreated to Yassy, and thence to Skuleni on the Pruth, where, under Athanasius of Agrapha, they sustained an attack from a body of Turks six times more numerous, refusing to fly, though the means of retreat were open to them, till three fourths of their number were destroyed. Another small party under Yorgaki, or George the Olympian, shut themselves up in the monastery of Secka, where they resisted the Turks for six and thirty hours. At length, when the enemy got into their rear, and success was hopeless, the gallant chief, having refused the safe retreat which the Turks offered him, called his followers together, and exhorted them to seek a glorious death sword in hand.

Finding that instead of seconding his heroic resolution, they were preparing to fly, he retired to the chamber where his powder was deposited, and uttering a short prayer, blew himself up, with four of his attendants. George was a native of Mount Olympus, and during this short campaign showed a prudence and courage which would have fitted him admirably for heading the insurrection; but the Greeks of that district were slaves to family titles, and George, who had no pretensions to rank, held only a subordinate situation. Quiet, modest, averse to intrigue, he seems, says Mr Gordon, to have been a real hero, inspired with sincere devotion, sublime courage, and an enthusiastic love of his country. With his death, on the 26th of August, all resistance ceased in the principalities. The intention of the insurgents was to erect European Turkey into a province for Prince Ipsilanti.

From the beginning of 1821 secret conferences were held by the more zealous Hetairists of the Morea, and a spirit of insubordination began to appear amongst the people. At length, on the 2d of April, the standard of independence was hoisted at Kalavrita, a town about thirty miles south-east from Patras, by Germanos, archbishop of Paleon-Patron, and Andreas Londos.[1] Two days afterwards the fighting began at Patras, where the Christian inhabitants rose on the Turks, and, during a bloody struggle of some days, a part of the town was burned. The Turks, however, retained the citadel, from which the Greeks had no means of expelling them; and Yusuf Pasha crossing the straits of Lepanto, the armed insurgents suddenly fled, leaving their brethren in the town to be butchered by the Turks. The insurrection spread with such rapidity over the Morea, that seven days after the first shot was fired, a Greek senate assembled at Calamata in Messina, under the presidency of Petras Mavromichalis, bey of Maina. A partisan warfare was carried on for some time against the small bodies of Mahommedan settlers living in the country, most of whom ultimately sought refuge in Tripolizza, the capital of the Morea. Meanwhile three thousand Albanians coming from the north, victualled the Acrocorinthus, and advancing to Argos, routed a body of Greeks posted there, killing seven hundred of them, and afterwards burned the town. The Kihaya Bey then proceeded to Tripolizza, and seemed resolved to act with vigour. The Greeks, who had now assembled a considerable force, were divided as to the mode of acting; but it was finally determined to fight, and they accordingly posted themselves at Valtezza, near the enemy. The Kihaya Bey, leaving Tripolizza with five thousand troops, attacked them on the 27th of May, but was repulsed in several attacks made on the village in that and the following day, and finally fled to Tripolizza, with the loss of two pieces of cannon and four hundred men. This victory, though small, had a great moral effect in raising the courage of the Greeks. The three great seats of Greek commerce, Hydra, Spezzia, and Psyra, entered into the revolutionary cause about the same time with the towns on the mainland. A small fleet of Hydriot and Spezziot vessels visited the other isles of the Ægean, proclaiming the independence of Greece, and was everywhere received with enthusiasm; whilst light-armed ships scoured the seas, and captured every Ottoman trader.

In Rumelia the insurrection broke out a few days later. The Armatolis, a sort of stationary Christian militia, in the mountains of Acarnania, Ætolia, and Thessaly, kept up by the Turkish government for the purposes of police, were unwilling to risk the loss of their pay. The peasants of Attica and Bœotia, however, took the field in the beginning of May; and on the 7th of that month, scaling the low wall which surrounds Athens, took possession of the town, and drove the Turkish inhabitants into the citadel. In Epirus, the remnant of the brave Suliotes, reinforced by other Greeks, and encouraged by Ali Pasha, harassed the Seraskier Kourschid Pasha, by cutting off his convoys of provisions. The scene of these hostilities was chiefly in the ancient Thesprotia, and it was carried on with great activity in May by Marco Bozzaris. From this district it spread into Acarnania and Ætolia; the independent flag was hoisted in Messolonghi in June, by several of the Armatoli chiefs; Vrakhori, a Mahommedan town twenty miles north of Messolonghi, was carried very gallantly, and some weeks afterwards Zarpandi in the same district; Salona was next taken; and the Turks in three months were deprived of a large proportion of the posts which they had occupied south of Mount Œta. Kourschid Pasha, however, made a vigorous opposition, and success often changed sides. In this desultory warfare the summer passed away. The Rumeliots, in the various actions fought, showed themselves much better soldiers than the Moreots, and this reputation they continued to maintain during the war. Whilst these events were passing, Mavrocordato arrived at Messolonghi from Leghorn, and, after conferring with the primates, went to Tripolizza, where the Moreot leaders were assembled for the siege. Finding he was an object of jealousy to Demetrius Ipsilanti, he returned to Messolonghi in September, and laboured to organize the insurrection in Rumelia. In the mean time Omar Pasha, with a body of four thousand Turkish troops, marched from Thessaly, routed a party of seven hundred Greeks at Thermopylæ, a second larger party under Odysseus at Scripu, and destroyed Livadia, the most flourishing town of Rumelia. He then advanced to Athens, and on the 30th of July relieved the citadel, in which sixteen hundred Turks had been blockaded for eighty-three days, by a motley army consisting of Attic peasants, Æginetans, and other islanders. The armed Greeks retired to Salamis and Ægina, and the Albanians of the pasha's army plundered and wasted the country. The Greeks now collected in small corps in the hilly districts of Bœotia and Phocis, straitening the communications of the Turks, and cutting off their supplies. A strong reinforcement coming to the latter from Thessaly, was routed at Thermopylæ by Odysseus, with the loss of eight hundred men. The pasha shortly afterwards withdrew from Attica and Bœotia, and the Athenians from Salamis re-occupied the town, and resumed the blockade of the citadel in November. In the extreme north the insurrection had been unfortunate. The Macedonian Greeks, who had taken refuge in the peninsula of Pallene, had their line of defence at Isthmus forced by Aboulaboud, and, except a portion who escaped by sea, were either killed or made prisoners. The monks of Athos capitulated to the same pasha, after two thousand of them had left the mountain. The people of Magnesia, when dividing the booty they had taken from the Mahommedans, were surprised and routed by the Pasha of Drama. A part sought shelter in the forests of Pelion, and part fortified themselves in the peninsula of Trikeri, or fled to the neighbouring isles of Scopelos and Skiathos. The thirty-five neat and flourishing villages of the district were mostly burned by the Turks. The Olympians, or Greeks of Pieria, also rose in arms, but at too late a period. The Pasha Aboulaboud had previously subdued the Christians of Athos and Macedonia, and being able to bring his whole force against them, routed them, and burned the 120 villages they possessed in the valleys of Olympus.

The Greeks of Macedonia, cruelly used by the Pasha of Salonica, were driven by despair to take up arms. Unable, however, to make head in the plain country against the Ottoman cavalry, they retreated to the peninsula of Cassandra, abandoning seventy villages, which the Turks burned. We must explain, however, that the rage of the Turks was excited to fury by the discovery of a plot formed by a Hydriot captain, to fire the arsenal at Constantinople, kill the sultan, and raise the Greek population.

---

[1] See *History of the Greek Revolution*, by M. Tricupi, Greek Ambassador in London, tom. i., p. 76, who gives rather a different version.

The government, alarmed by this event, seized and executed the leading individuals of the Fanariot families, whilst some thousands of the other Christian inhabitants were massacred in their houses, without the least regard to legal forms. The death of the patriarch, a very old man, much esteemed for his virtues, and of a number of the other high clergy, created a great sensation. Salonica, Adrianople, and Smyrna, were the scene of similar barbarities. The last of these towns, in particular, was consigned to a general sack, like a city stormed. Kydonia, a Greek town with thirty thousand inhabitants, which had grown up in a few years, and was renowned for its college, where three hundred students received a superior education, falling under the suspicion of the Turks, was burned to the ground, and its people were forced to seek refuge in Psyra and other isles. The Greek ships, which were merely merchant vessels, carrying from twelve to twenty-four guns, would have been impotent against any navy but the Turkish; but by their superior seamanship, and a bold and skilful use of brulots or fire-ships, they often baffled or defeated strong squadrons of large men of war. Their first exploit of this kind was the burning of a Turkish seventy-four on the coast of Mytelene in June. This paralysed the operations of the capitan-bey for a little; but setting forward again, he arrived at Samos, the poor but brave inhabitants of which, forty thousand in number, had slain their Ottoman rulers, and now harassed the Turks of the neighbouring continent by frequent descents upon the coast. A large land force was collected to subdue them, and the capitan-bey attended with the fleet to co-operate. But the Turks were defeated with great loss in an attempt to land a thousand men, and a second armament was intercepted by the Greek fleet, who burned ten transports, whilst the soldiers escaped to the shore. The troops after this refused to embark. The Greek and Turkish fleets manœuvred in presence of each other, but parted without fighting, after the former had burned several fire-ships without effect.

Demetrius Ipsilanti, second brother of Alexander, travelling in disguise from Russia, landed at Hydra in June, and thence sailed over to the continent, where he was welcomed with extraordinary demonstrations of joy. He brought a small supply of money and arms, and a commission from his brother, investing him with the supreme command of the army. Patriotic, upright, brave, and accomplished, he unfortunately wanted the energy necessary for the post he assumed, and soon found himself thwarted in his views, and rendered incapable of effecting any thing, by the jealousy of the bishops and military chiefs. Prince Mavrocordato, another Greek of noble descent and considerable talents, arrived in the Morea a few weeks later. The Turks at this time were driven out of the open country, but held nine fortresses in the Morea, Patras, the castle at the adjoining straits, Navarin, Coron, Modon, Nauplia, Acrocorinthus, Monemvasia, and Tripolizza. The Greeks wanted both materials and skill for conducting regular sieges, and merely kept most of these places blockaded less or more strictly. Monemvasia, and afterwards Navarin, surrendered in August, in consequence of famine. The one capitulation was pretty faithfully kept; the other was most disgracefully violated by the massacre of the Turks, to whom a safe retreat had been guaranteed. The siege of Tripolizza was pressed with a little more vigour, as it was the capital of the peninsula, and contained a number of wealthy Turks, whose property was looked to as the prize of conquest. The city was defended by a wall fourteen feet high and two miles in circuit, flanked by a few towers with cannon, and its population was increased by refugees to 25,000 souls. The besieging army amounted to about 4500 men, which was less than the number of adults within the walls; it gradually swelled, however, as the increasing scarcity in the town multiplied the chances of a surrender. The contest was carried on by trifling skirmishes, till the Turkish cavalry, which was the only force dreaded by the Greeks, being entirely ruined, the besiegers were enabled to invest the place more closely. Famine was now doing its work upon the unhappy Moslemins, who were negotiating for a capitulation on the 5th of October, when some Greeks mounting a part of the wall which had been neglected (there was no truce), entered the town, and were immediately followed by the rest of the army. The place was completely sacked, and of ten or twelve thousand inhabitants, young and old, of both sexes, still remaining in it, about eight thousand are supposed to have been slain. A number of women were carried off as captives, and a few officers were spared for the sake of the ransom expected for them. Some Turks sold their lives dearly, and a party of forty cut their way through the Greeks, and escaped to Nauplia. The booty in money, shawls, jewels, dresses, pistols, sabres, and other articles, was very great, and led to petty contests amongst the victors. The town presented the aspect of a ruin. As a small counterpoise to this loss, the capitan-bey destroyed the village of Galaxidi, near Salona, and carried off thirty-four small trading vessels, the property of its industrious inhabitants. The Ottoman fleet at the same time revictualled Modon, Coron, and Patras. The Greeks made an attempt to surprise Nauplia, which would have succeeded but for the cowardice of the Moreots; and a large body blockading the castle of Patras were, owing to their gross carelessness, surprised and routed by a party of Turks who crossed at Lepanto. Thus terminated the year 1821.

The Turks of Crete, inspired with alarm by the appearance of Greek cruisers in the adjacent seas, began to strip the Christian inhabitants of their arms, and to butcher many of them in cold blood. A number of the latter, comprehending the brave and hardy mountaineers of Sphakia, were driven by this cruel usage to fight for their lives. In July, August, and September 1821, the insurgents, about twelve hundred in number, repeatedly defeated large bodies of Turks; but the pasha at length collecting an army of ten thousand men, overpowered them, and burned most of their villages.

A national assembly convoked by Prince Ipsilanti had met at Argos about the end of 1821, but finding that position insecure, it removed to Piada, near the ancient Epidaurus, in January 1822. The assembly chose Mavrocordato president, and adopted an organic law or constitution, framed on republican principles. The government was to consist of a senate of seventy members elected annually by the people, and an executive council of five persons. The constitution enacted equality of rights, the freedom of the press, and toleration in religion. The government was then organized. The executive council consisted of Mavrocordato, president; Kanakaris, Logotheti, Delhyani, and Orlando, members; and Theodore Negris, secretary. Seven ministers were also appointed for finance, foreign affairs, war, &c., whose names it is unnecessary to give. After passing a decree for a loan of 5,000,000 of piastres, the assembly closed its session on the 20th of January. The government thus erected proved a mere phantom. It had no means of coercing the military chiefs, who set its powers at defiance, and disdained even to pay it marks of outward respect.

The citadel of Corinth, a post of great importance, surrendered on the 26th of January 1822, when the Turks were inhumanly slaughtered, in violation of a compact to convey them away in safety. The Greek government fixed itself here for some months, and issued a variety of decrees, which were very little attended to. The death of Ali, pasha of Yanina, who was shot by the Turks in February, after giving himself up on a promise of personal safety, made a considerable change in the position of the Greeks. Kourschid Pasha shortly after sent an army of 17,000 men to attack the Suliotes, who, though numbering only 4000 warriors, including Epirots, made so obstinate a resistance with the aid of their rocks and woods, that the Turks were finally compelled to retreat with a heavy loss, and the pasha had no resource but to turn his active hostilities into a blockade. Mavrocordato arrived at Messolonghi in June, commissioned to act as captain-general of Western Greece. Anxious to succour the Suliotes, he marched northward with 3000 men to Petta near Arta. Here he was attacked by 10,000 Turks, and in consequence of the treachery of Gogos, one of the Armatoli chiefs, his little army was overpowered, and lost four hundred men, including two thirds of the small corps of disciplined Philhellenes. He made his way back to Messolonghi; and the Suliotes, reduced to extremity, signed a capitulation with the pasha, by which the existing remnant of three hundred and twenty men, and nine hundred women and children, were transported to Cephalonia, with their arms and baggage, at the pasha's expense, with a douceur of two hundred thousand piastres superadded. Released from this troublesome enemy, Omar Pasha approached Messolonghi in October with ten thousand men. The town had scarcely any defences, and the garrison being under four hundred men, he might have carried it by a *coup-de-main.* He spent some weeks, however, in a state of inaction, or in trifling negotiations, and this interval Mavrocordato diligently improved, by raising new works, whilst a reinforcement of men from the Morea increased the garrison to upwards of 2000 men, and the Greek fleet brought supplies of ammunition and arms. The rainy season too having set in, spread sickness through the Turkish camp; and the pasha, now aware of his error, and anxious to retrieve it, attempted to carry the works by escalade before daylight on Christmas morning, when he supposed the Greeks would be at their devotions. They had previous information, however, and beat back the Albanians at every point, with the loss of six hundred men. The pasha now began his retreat, obstructed by the swoln rivers, and harassed at every step by the Acarnanians, who where up in arms; he reached Previsa with the wrecks of his army in February 1823.

In the Ægean Sea the spring of 1823 was marked by the most unfortunate and tragical event which distinguished the revolution; the entire destruction of the happy and prosperous Greek community of Scio. This island contained 120,000 Christian inhabitants, whose peaceful habits, intelligence, industry, and wealth, exhibited a picture of civilization unrivalled in the other parts of the Turkish empire. They were unwarlike, but being mildly governed, they desired no change. When the Hydriot fleet appeared, they entreated the admiral to leave their coast, and not compromise them with the Porte. Two adventurers, however, one of them a Sciot by birth, who had spent his life abroad, the other a Samian, in an evil hour, planned an expedition to dislodge the Turks, which was too feeble and ill supported to accomplish its object, but strong enough to alarm the Porte, and bring ruin on the unhappy islanders. Leaving Samos in March 1822, with a flotilla of eight brigs and thirty launches, filled with one or two thousand men, the two adventurers, Bournia and Logotheti, disembarked near Scio, and entered the town without experiencing any resistance. They were coolly received by the inhabitants, who dreaded the vengeance of the Turks; but the citadel with a stout garrison held out against them, and disturbed them by frequent sallies. A month passed away thus, when the Ottoman fleet suddenly appeared before the town, and driving off the few Greek ships stationed there, conveyed over a part of an army of thirty thousand men collected on the opposite Asiatic coast, which is only ten miles distant. The Turks carried the town by assault on the 15th of April, putting to death the men, young and old, without mercy, and not even sparing women and children. A part of the town was burned, and what escaped the fire was destroyed otherwise. For a month crowds of armed barbarians wandered over the island, wasting and plundering. It was calculated that 25,000 of the Sciots were slaughtered, and 45,000 dragged into slavery; 15,000 were saved at first in the Mastic villages, the property of the sultan, but were afterwards massacred; the rest escaped, or were absent when the catastrophe occurred; but those who saved their lives lost every thing else, and the most opulent families of which Greece could boast were thus reduced in an instant to beggary. In August the island did not contain above 1800 Greeks, out of the 120,000 who peopled it in March. If the Hydriot fleet had appeared in proper time, the Turks could have been prevented from disembarking, and, with moderate diligence, the town might have been secured against a sudden assault. But the insurrection was no less rashly planned than ill conducted, and the horrors in which it terminated filled all Greece with unavailing lamentations. A strong fleet sailed from Hydra when it was too late; but it achieved nothing except burning the Turkish admiral's ship, in which more than 2000 men perished. This exploit was accomplished in a very gallant manner, by Canaris, a high-spirited patriot, whose name, and that of Miaulis, are associated with the most brilliant achievements of the Greek navy in the history of the war.

In Eastern Greece a desultory warfare was carried on in the spring of 1822. The Greeks of Mount Œta, Othrys, and Pelion, harassed the Turks in the south-eastern plains of Thessaly, but without gaining any advantage. An attempt was made to dispossess the Mahommedans of Eubœa, but it miscarried. The Athenians had tried to bombard their citadel, but they wanted skill and an adequate supply of projectiles; they then mined parts of the wall, but could not produce a practicable breach. At length, however, famine did their work. The Turks capitulated on the 22d of June, and though their personal safety was guaranteed, a large number of them were, as usual, massacred in cold blood, and the rest were saved with difficulty by the Frank consuls.

Kourschid Pasha had been collecting a large force in Thessaly, but the Greeks, with their usual negligence and want of foresight, though apprised of the fact, made no defensive arrangements till the enemy was in the heart of their country. The Turkish army, twenty or thirty thousand strong, chiefly cavalry, with a small body of infantry and artillery, crossed the Sperchius, seized the defiles of Mount Œta, and entered Bœotia in the beginning of July. Odysseus, who had charge of the Pass of Thermopylæ with 4000 men, either from weakness or treachery, offered no resistance. The Pasha Dramali, the commander of this army, burned Thebes, passed Cythæron and the Dervend of the isthmus unopposed; and the impregnable castle of Corinth, though victualled for three months, fell into his hands by the pusillanimity of the garrison, without firing a shot. From Corinth he pushed on to Nauplia, the Greeks everywhere leaving their houses and flying in the utmost consternation at his approach. No one thought of fighting, till Demetrius Ipsilanti threw himself with a small party into the ruined castle of Argos, not with the hope of making an effectual resistance, but in order to gain time, and induce the fugitives to rally. The manœuvre succeeded. A pause took place in Dramali's operations, during which Colocotroni arrived from the interior with a considerable force, which he drew up between the mountains and the sea near Lerna, strengthening his position with some hasty works calculated to render useless the cavalry, which was the pasha's right arm. After skirmishing for one day, with little success, the Greeks wisely resolved to wait the effect of scarcity upon their enemies, having previously burned all the standing corn. The Turks soon exhausted their stock of provisions by their wasteful habits, and Dramali had neglected to secure his communications with Corinth and Northern Greece, by guarding the passes. The insalubrity of the soil, and the inconsiderate use of unripe fruit at the same time, gave birth to fevers, which cut off numbers of his men; whilst the cattle brought for food, and the cavalry horses, died in thousands from want of fodder. Pressed by these evils, and unable to force the entrenchments in his front, he began his retreat on the 5th of August. The Greeks, however, who had divined his purpose, stationed some thousand men in the mountainous defiles, who assailed him in his flight, and, besides killing 2000 of his soldiers, captured all his treasure and baggage, with a vast number of horses, mules, and camels. Many more of the Turks died at Corinth, where marsh fevers prevailed, and amongst these the commander, Mahmoud Dramali. A great number of the survivors were destroyed in an attempt to reach Patras by land; and at the commencement of winter only a small remnant was in existence of the formidable army which, three months before, seemed powerful enough to overwhelm Greece.

The Palamede, or castle of Nauplia, pressed by famine, capitulated in the end of December; and for once the Turkish prisoners were allowed to depart in safety. The Greeks who held the citadel of Athens gave up the command of it to the crafty and treacherous Odysseus, a choice of which they had reason to repent. The Turkish fleet, instead of supporting the army, sailed round the Morea to Patras, and on its way back to the Hellespont a ship of the line was burned by the intrepid Canaris.

In February 1823 a second Greek congress assembled at Astros in Argolis, and was attended by 260 deputies. Feuds ran so high between the parties that it was difficult to prevent bloodshed. It broke up at the end of April, having appointed Petro Bey president of the executive council, and fixed Tripolizza as the seat of the government. Its decrees, however, were treated with contempt by the military chiefs, who soon compelled the executive to seek refuge in Salamis. The transient gleam of prosperity caused by the retreat of the Turks had kindled a violent spirit of disunion; and the nation was now rent into factions, headed by men like Colocotroni, Petro Bey, Londos, Delhyani, Odysseus, Ghouras, and Panourias, who, having been originally *klephts* or robbers, retained the craft, ferocity, and rapacious habits of their primitive vocation, and, when the enemy was no longer present, thought of nothing but plundering the people, and assassinating one another. The men of better principles, Mavrocordato, Ipsilanti, and Conduriotti, armed only with resolutions of the national congress, had no power to awe these ruffians and their military bands into obedience. The country, in fact, was everywhere a prey to anarchy, and as early as 1823 the wiser part of the people began to broach the scheme of inviting a foreign prince to accept the sovereignty of Greece.

In the early part of the year 1823 the Turks of Eubœa made predatory incursions into Attica and Bœotia; whilst the Greek mariners of Psyra and Samos made descents on the coasts of Asia Minor, plundering the towns, and carrying off wealthy Mahommedans prisoners for the sake of the ransom obtained for their liberation. In June, however, a Turkish army of 6000 men broke into Phocis and Doris, and advanced to the neighbourhood of Athens. The Greeks, as before, avoided battles, but encamping on the heights, cut off detachments and foraging parties; and ultimately this force melted away by casualties or desertion, without accomplishing any thing of importance. An expedition undertaken by Odysseus to drive the Turks from Eubœa miscarried; and the Christians of that isle having risen in arms, were vanquished, and compelled to seek refuge in the isles of the Ægean, after witnessing the destruction of the 150 villages they possessed. The principal effort of the Turks, however, was made in Western Greece. The Pasha of Scodra led an army of 5000 Mirdites or Albanian Christians into Acarnania. Messolonghi at that time was without men or arms, and almost defenceless. Marco Bozzaris, a brave Suliote, with a small corps of his countrymen, finding himself unable to arrest the pasha in his march, conceived the bold idea of surprising him in his camp. The attack was made in the night time; but of the three parties of Souliotes, two slunk back; and the third, led by Bozzaris, consisting of only 350 men, after storming several tambourias, and making a horrible slaughter of the enemy, finding itself unsupported, retired with the loss of one third of its number, including its intrepid commander. The Pasha of Scodra now joined Omar Vrioni, and the two approached Messolonghi; but the town was by this time garrisoned and provisioned; and the Ottoman commanders having an extravagant idea of its strength, turned aside to besiege Anatolico, a paltry village a few miles distant. They bombarded it for some weeks, till the rains setting in, and spreading sickness amongst their troops, forced them to retire in November. No solicitations could induce the Pasha of Scodra to engage in the invasion of Greece a second time.

In Crete the insurrection opened in 1823 with a promise of success, which was not realized. Affendouli, the former chief of the insurgents, having lost his influence, resigned; and Tombazi, a Hydriot, and an able but rapacious man, was elected leader in his place, and dignified with the Lacedemonian title of Harmost. He arrived in Crete with 1200 Rumeliots and Moreots, and a few small armed vessels, early in the summer, and being joined by the Sphakiots, gained several advantages over the Turks. Kissamos, a fortified post, fell into his hands by capitulation, but his troops were routed at Khadeno, and failed in an attack upon the Mahommedans of Selino. The sea being in the mean time open, the Pasha of Egypt disembarked two successive bodies of disciplined troops. The last of these, which landed at Canea in September, routed the insurgents in the neighbourhood of that town, and carrying fire and sword throughout Sphakia and the other disaffected districts, completely extinguished the insurrection. In the course of the year the capitan-pasha sailed as far as Patras, and afterwards paraded his fleet about the Ægean; but the whole extent of his achievements consisted in relieving Carysto, and reducing the Magnesians of Trikeri; whilst some of his smaller vessels were run ashore and destroyed by the Greeks. The citadel of Corinth, after a blockade of nine months, surrendered in November to Nikitas, who, in terms of the contract, faithfully secured the unmolested retreat of the Mahommedans. Whilst the Greeks thus prospered externally, there was nothing but dissensions among themselves. "The members of the executive," says Mr Gordon, "with the exception of Zaimis, were no better than public robbers.... Every corner of the Morea was torn to pieces by obscure civil contests, and hardly any revenue came into the treasury."

The efforts of the Greeks to liberate themselves from the Turkish yoke had from the first excited the sympathies of Western Europe; and in 1823, when their resistance began to rise above the character of a transient rebellion, these sympathies produced small succours in men and money. In England, France, Germany, and Switzerland, subscriptions were raised, the value of which was generally sent out in ammunition or military stores. Small corps of volunteers, actuated by a fine enthusiasm, also went from Western Europe, and though universally disgusted with the treatment which they received, they always fought bravely, and often rendered very important service. Amongst these foreigners, who received the appropriate name of *Philhellenes*, no one was the object of such universal interest as Lord Byron. His lordship disembarked at Messalonghi with 8000 dollars in specie, on the 5th of January 1824, and was received with the most extravagant marks of joy. Shortly afterwards Lieutenant Parry arrived with some small field-pieces, supplies of powder, shot, and tools, sent by the Greek committee in London. His lordship took into his pay a corps of 500 Suliotes, whose insolence and rapacity rendered it soon necessary to expel them from the town, or rather to purchase their absence with a sum of money. The Rumeliots who replaced them were not much better; and Byron found himself so incessantly teased for money, so distracted by the turbulence of the military, the intrigues and dissensions of the different parties, that his mental anxiety preying on his frame, produced a shock of apoplexy, by which his health was seriously injured. A fever followed some time afterwards, and carried off this gifted man, on the 19th of April, amidst the lamentations of the Greeks, who atoned in some degree for the vexation they had caused him, by the sincere homage which they paid, and still pay, to his memory. After his death the mutual jealousies of the chiefs became more violent than ever, and the summer passed away in a state of comparative inaction. Mavrocordato advanced with 2000 men to the Gulf of Arta in August, and skirmished with the Turks, till the rains in November forced him to retire. In the east a body of Turks, who penetrated into Bœotia and threatened Athens, retired without effecting any thing. Ghouras, who held the citadel of that town for Odysseus, having quarrelled with the latter, got him into his power, and put him to death.

The naval campaign of 1824 was signalized by two unfortunate events. The small and prosperous isle of Kasos, of which Savary gives so interesting a description, was invaded by an Egyptian force, and entirely ruined, 2000 of its inhabitants being sold into slavery. The Porte, greatly exasperated by the active hostilities of the Psyriots, whose ships preyed on the Ottoman trading vessels, and insulted the coasts of Asia Minor, sent a powerful fleet against them under the capitan-pasha, with 14,000 troops on board. The island of Psyra is small and barren; its rocky coasts render disembarkation difficult; and its inhabitants, whose numbers had been increased to fifteen or twenty thousand by emigration from Scio, trusting to their courage and the natural strength of their territory, had taken no pains to secure themselves by artificial works. The small Greek fleet stationed off the harbour fled at the approach of the Moslemins, who, under cover of a false attack, landed a strong force at the north extremity of the isle, and gained possession of the hill which rises above the town. This unexpected success produced a panic among the timid refugees, which spread from them to the Psyriots; men and women threw themselves into the boats and attempted to escape, whilst the Turks entered the town unresisted, and laid it waste with fire and sword. In the midst of this miserable rout, a band of 600 refugees from Mount Olympus and other parts of Macedonia distinguished themselves by a feat of heroism worthy of ancient Greece. Throwing themselves into the convent of St Nicholas, where they had placed their wives and children, they resisted the attacks of the whole Turkish army, till two thirds of their number were killed. All hopes of relief being at an end, they resolved to blow up the convent. Their fire having accordingly ceased, the Turks scaled the walls on every side, when suddenly, says Gordon, the Hellenic flag was lowered, a white banner inscribed with the words *Liberty or Death* waved in the air, a single gun gave the signal, and a tremendous explosion, shaking the isle, and felt far out at sea, buried in the ruins of St Nicholas thousands of the conquerors and the remnant of the conquered. This happened on the 5th of July. Only two of the Greeks were taken alive. The loss of life was great in Psyra; and the island, which might have been saved by a little foresight and exertion, was completely ruined. After the deed was done the Greek fleet appeared, took some Turkish vessels, and destroyed a small corps of Janizaries left on the island. From Psyra the capitan-pasha proceeded to Samos, but here all his movements were watched by the Greek fleet; and his attempts to convey over an army from the mainland were not only defeated, but he lost three ships of war and a thousand men, and at last retired from the shores of Samos completely baffled.

The sultan, made sensible, by the failure of three campaigns, of the inefficiency of his own fleets and armies, delegated the task of re-conquering Greece to the Pasha of Egypt, whose ambitious views made him listen readily to the request of his nominal superior. In the beginning of August, Ibrahim, the pasha's adopted son, sailed from Alexandria with a powerful fleet of ships of war and transports, amounting altogether to 400 sail, with 17,000 men on board, 2000 horses, and a strong train of artillery. He put into the bay of Macri, the ancient Telmessus, to water, and shortly afterwards was met by the Greek fleet of seventy sail, carrying 700 guns. For more than three months Ibrahim manœuvred amongst the gulfs and isles on the coast of Caria, endeavouring to beat off the Greeks, and proceed on his voyage; but though he counted six guns and six men for every one his enemies could muster, his mariners were so wretchedly deficient in skill, that he was continually baffled, and at last thought himself fortunate in escaping to Crete in the beginning of December, with the loss of two fine frigates and four brigs of war blown up, fifty transports taken or sunk, and 4000 soldiers and seamen slain or drowned, exclusively of some thousands who died of disease.

The first Greek loan was negotiated in London in February 1824. The nominal amount was L.800,000, of which all that was available, after deducting interest, commission, sinking fund, &c. was L.280,000. It served to quicken the operations of the government, and no doubt contributed materially to the success of the fleet, and the defeat of Ibrahim. In the Morea fierce civil war raged, Colocotroni, Londos, Sisini, and other robber chiefs, setting the government at defiance. They were crushed, however, by the vigorous efforts of Colletti, the secretary; but the Rumeliots, by whose agency he put them down, proved a scourge to the country by their rapacity.

Ibrahim having procured reinforcements from Egypt during the winter, set sail from Suda in February 1825, and landed with 4000 men at Modon on the 24th, a day pregnant with sorrow to the Greeks. The success of their naval efforts in the preceding year showed that, with common activity, they might have prevented the disembarkation; but no precautions were thought of, partly from want of foresight, partly from a feeling of false security, which led them to think that the Egyptians would be as feeble adversaries as the Turks. Ibrahim attempted nothing till he had brought over additional corps, and raised his army to 11,000, and afterwards to 15,000 men. He then commenced the siege of Navarin, defeated 7000 palikars who tried to relieve it, breached the walls, carried some outworks after hard fighting, and gained possession of the place by capitulation on the 18th of May. Thence he advanced into the interior, burning the villages, which the Greeks deserted on his approach. Colocotroni endeavoured to arrest his progress in the mountainous defiles, but without success; Tripolizza was burned by its inhabitants; and Argos shared the same fate at the hands of the Egyptians. Nauplia was threatened, but

Ibrahim had no battering artillery; and dreading the want of provisions, he retreated towards Messenia. The Greeks, who had assembled to the number of 7000, attacked him near Tripolizza, but were beaten so completely that they gave up all further thoughts of resistance in the open field. In August and September the pasha ravaged the valleys of the Alpheus and the Eurotas, destroying the town of Misitra and a number of villages, and then returned to Modon. One or two gallant feats were performed by the Greeks during this unfortunate campaign. A small body of 300 men under Papa Flessas, surrounded by many thousand Egyptians, defended themselves with the bayonet and the but-ends of their muskets, till the whole perished except two, who lay hid under the slain; and at the Mills of Lerna, Ipsilanti, with a few hundred men, baffled the main body of the pasha's army.

In Northern Greece, Redschid Pasha, the most energetic of all the sultan's officers, had been intrusted with the conduct of the war. Leaving Yanina, he arrived in May before Messolonghi, which contained about 5000 of the bravest Greek soldiers, and opened trenches. The works were carried on with vigour, in the face of a most determined resistance. Elevated mounds were raised to command the batteries of the besieged, and mines were sunk; the Franklin bastion, the most exposed part of the defences, was laid open by breaching, and repeated attempts were made by the Turks to take it by assault, in one of which they at length succeeded; but the Greeks, no way daunted, sprung a small mine, and rushing upon their enemies sword in hand, dispossessed them, and following the Turks into their lines, destroyed some of their batteries. Fresh efforts were made by the pasha, and still frustrated by the courage of the Greeks, till the winter rains in October compelled Redschid to suspend his operations, and coop himself up within a fortified camp near the town. Ibrahim, who had received a great accession of force in November, now determined to try a winter campaign, and gratify the Porte by conquering Messolonghi. Marching northward, he burned the villages of Elis, and crossing the Straits of Lepanto, encamped before Messolonghi in January 1826. He began by offering terms to the besieged, which were proudly rejected. His batteries were more skilfully constructed than those of the Turks, and his artillery better served; but after he had ruined part of the town's defences, his attempts to storm were constantly defeated by the Greeks, who, in fighting hand to hand, with sword or bayonet, were vastly superior both to the Turks and Egyptians. The siege would indeed have ended in total failure, if he had not succeeded, at a great expense of life, in reducing various outworks commanding the channels of the lagoon by which the besieged communicated with the sea, and received supplies of provisions. Starvation now accomplished what arms could not achieve. After every thing edible, whether wholesome or unwholesome, was consumed, the remainder of the gallant garrison adopted the resolution of cutting their way through the enemy's lines. A deserter betrayed their plan to the pasha, who was fully prepared to receive them. Formed into two bodies, they issued from the town by moon-light on the 22d of April; a false alarm induced the one to return: the other, raising a simultaneous shout, "On, on, death to the barbarians," rushed forward with their muskets in their hands, and their sabres slung to their wrists. "Neither ditch nor breastwork," says Gordon, "neither the flashing peals of cannon and small arms, nor the bayonets of the Arabs, could arrest the tremendous shock; in a few minutes the trenches were cleared, the infantry broken, the batteries silenced, and the artillerymen slaughtered at their guns." Of the other body which returned to the town, some escaped in boats, some by wading through the lagoon, some voluntarily blew themselves up with a number of the enemy, when the latter entered the powder magazine, and not a few of the survivors died of fatigue and exhaustion before they reached Salona. The heavy loss of the Turks and Egyptians during the siege attested the superior valour of their enemies; and the heroic defence of Messolonghi may well vie with the proudest achievements of ancient Greece.

In Eastern Greece, Colonel Fabvier, a brave and zealous French officer, formed a corps of regulars or tacticos, and carrying them over to Eubœa, made an attempt on Carysto, which failed. No drilling, in fact, could induce the palikars, or Greek irregulars, who had been accustomed to rely entirely upon their strength, agility, and adroitness, to meet a steady fire when drawn up in line. Another national assembly was held at Piada in Argolis, but it effected nothing. After the fall of Messolonghi, Redschid Pasha invaded Attica, and took Athens, but failed in his attempts upon the citadel, into which, when its garrison was greatly reduced, Colonel Fabvier introduced 600 men, with a supply of powder. The glorious fall of Messolonghi had awakened an enthusiasm in Western Europe in favour of the Greek cause, and contributions to the amount of not less than L.70,000 were raised in 1826. The royal families of Bavaria, Prussia, and Sweden, and the king of France, were amongst the contributors.

In May 1827 Ibrahim invaded the country of the Mainots, but was defeated in all his attempts to penetrate their mountain fastnesses. The rest of the summer was spent in ravaging the open country, and burning the villages, the inhabitants of which took refuge in woods and caverns. To his great mortification, none of the people made their submission, and parties of irregulars watched his movements, cutting off stragglers, and intercepting convoys. Lord Cochrane arrived in Greece in March 1827 with a steam-frigate. A very splendid frigate, built in America, also reached Ægina this year, but proved of no great use, the Hydriot mariners being unaccustomed to manage vessels of such a size. These two frigates were nearly all that the Greeks derived from a second loan of L.2,000,000 negotiated in London in February 1825.

General Church, an Englishman who had served in a Greek corps formerly kept in English pay in the Ionian Isles, arrived by invitation about the same time. They found the Greeks rent into factions furiously hostile to each other. It is a memorable fact, that whilst Ibrahim was wasting the Morea, there were no less than seven petty civil contests raging in different parts of Greece! By the influence of Church, Cochrane, and Captain Hamilton of the Cambrian, a temporary reconciliation was effected between the adverse parties, and the necessity of having a foreign chief being generally acknowledged, a congress assembled at Trœzene in April, and elected Count Capo d'Istrias president for seven years. Church was appointed general of the land forces, and Cochrane admiral of the fleet. The fortunes of Greece were now at a very low ebb; but what power remained in the country was summoned up in an expiring effort. From the Morea, the isles, and Western Greece, a force of nearly 10,000 men was collected at Salamis and the Piræus. After carrying on a war of posts, chiefly at Port Phalerus, for some time, General Church was persuaded to risk a battle with the Turks in the plain of Athens, the object being to relieve the citadel. The result was a disastrous defeat on the 5th May, in which the Greeks lost 1500 men. The remaining troops dispersed, and the citadel capitulated. The only fortified posts now in the hands of the insurgents were Nauplia and the Acrocorinthus.

Relief was, however, approaching from another quarter. From circumstances which it would be tedious to explain here, the policy of the great Christian powers had undergone a change. A protocol had been signed at Petersburg in April 1826, by the Russian and British ministers, the object of which was to effect an accommodation between the Porte and the insurgents, by erecting Greece into a dependency of the Porte, paying a fixed tribute, but having the entire regulation of its own affairs. On the 6th July 1827 a treaty of intervention was signed between France, Russia, and Britain, on the same basis. The sultan firmly denied their right of interference, for which, however, the piracy practised by the Greeks gave them a good pretext. A naval force was sent into the Mediterranean to inforce the provisions of the treaty, and the belligerent parties in Greece were enjoined to suspend hostilities. The Greeks joyfully agreed; but Ibrahim hesitated, as the measure was not sanctioned by the sultan; and the capitan pasha, who was lying in the harbour of Navarin with a strong Turkish fleet, having similar scruples, the warlike movements were partially continued. The combined fleets of England, France, and Russia, stood into the Bay of Navarin in order of battle on the 20th October. Though the intention of the admirals was to treat, the Turks believed they came to fight, and were anchored in smooth water to receive them, and supported by batteries on shore. Who began the battle is uncertain; but it was obstinate and bloody, and most destructive to the vanquished party. About 6000 Turks were slain, and of 120 men of war and transports, all were sunk or destroyed except twenty or thirty brigs and corvettes. The killed and wounded on the side of the allies amounted to 626. The victory produced unbounded joy among the Greeks, and excited them to make a new attempt upon Scio, by an expedition under Colonel Fabvier, which, though conducted with great courage and skill, ultimately failed. Ibrahim, seeing his communications with Egypt now cut off, obtained his father's authority, and agreed to evacuate the Morea. He sailed in the beginning of October 1828, leaving, according to stipulation, about 8000 troops in Patras, Modon, Coron, Navarin, and Castle Tornese, of whom 1200 were Egyptians. To avoid renewed hostilities between the Greeks and Turks, a French army was sent to the Morea in the autumn, and took possession of these five fortresses, the last being the only one that offered any resistance.

Count Capo d'Istrias passed from Petersburg to London and Paris in the end of 1827, and after conferring with the British and French ministers, he set sail from Toulon, and landed at Nauplia on the 18th of January 1828. The people received him with great joy, hoping to find repose and security under his government; and his authority was acknowledged at once by the military chiefs and other functionaries of all descriptions. He was a clever and dexterous diplomatist, but his conduct as president seems not to have been judicious. Anxious to copy the centralising system which prevails in absolute monarchies, he dissolved the municipalities, and nominated prefects, judges, and other officers, deriving their authority entirely from himself. Many of his appointments also gave offence: among others, the nomination of his brother Augustin, a person of no ability, to the command of Western Greece, led to the resignation of General Church in 1829, after that officer had recovered all the country south of the Gulf of Arta from the Turks. The French troops, it is to be observed, confined themselves to the Morea, such being their instructions, and left the Greeks to carry on hostilities in the north with their own means.

The Porte obstinately rejected the arrangement proposed by the three powers in 1827, till it was humbled by numerous defeats in 1828 and 1829, and saw the Russian army within a few leagues of its capital. The stipulations in behalf of Greece made by Nicholas were, however, set aside by the governments of France and Britain, and it was settled that the affairs of that country should be discussed in London. The conference held there, after much deliberation finally resolved that Greece should be erected into a monarchy entirely independent of the sultan, and ruled by a Christian prince. The crown was offered, in the end of 1829, to Prince John of Saxony, who refused it; and then to Prince Leopold of Saxe-Cobourg, who agreed to accept it; but having corresponded with Capo d'Istrias, the latter artfully infused so many doubts and apprehensions into the prince's mind, that he resiled from his engagement. This was in May 1830. Other princes, it is said, were proposed, but nothing was decided; and in the mean time Greece was again falling into a state of anarchy. The popularity of Capo d'Istrias' government was of short duration. Visibly the partisan of Russia, he showed a devotion to her interests which offended all the more independent Greeks. He extinguished the freedom of the press, which the people were perhaps more eager to possess than fitted to enjoy; established a council, called the Panhellenion, which was intended to supersede the elective senate; refused to publish any account of the national finances, and threw many popular leaders into prison. These and other measures produced violent discontents, which at last broke out into open rebellion. The Mainots, whose prince he had placed in durance, were the first to throw off his authority. They were followed by the people of Hydra, who established a provisional government, at the head of which were Miaulis and Condouriotti, assisted by Mavrocordato. The French and English ships of war in the Archipelago stood neutral; but the Russian admiral, Ricord, eagerly took a part in the contest, on the side of the president. With this aid he attacked Poros, where the Greek fleet lay; but the islanders had anticipated his design, and, when the loss of their ships of war became inevitable, blew them up to prevent them falling into his hands. Whilst this contest was going on, the son and brother of Mavromichaeli, the captive bey of Maina, instigated by a feeling of revenge, came to Nauplia and assassinated the president at the door of a church, on the 9th of October 1831. One of the assassins was murdered on the spot by the people, and the other was seized, tried, and executed. A new commission of government was then appointed, consisting of Augustin Capo d'Istrias, with Coletti and Colocotroni, who thought it prudent to convoke a national assembly. Loud complaints were made that the free choice of the people was defeated by force and fraud; and when the assembly met in December, it speedily separated into two hostile bodies, one of which remained at Argos, while the other seated itself at Megara, and thence fulminated decrees against Augustin and his associates. The Moreots generally adhered to the former, the Rumeliots to the latter. Civil war now raged furiously in the country, and the peaceful cultivators were driven, as in the time of the revolutionary struggle, to desert their homes, and seek refuge in the woods and caverns. This lamentable state of things probably quickened the languid proceedings of the conference in London, who in May 1832 fixed upon Otho, second son of the king of Bavaria, as the sovereign of Greece. The prince was born in 1815, and was of course a minor; but the defect was supplied as far as possible by a council of regency. The three powers, parties to the conference, obtained an extension of territory and a better frontier for the new state, including the province of Acarnania, for which, however, a price was to be paid to the sultan; and, in order to put Otho in a condition to meet initiatory difficulties, they guaranteed a loan of L.2,400,000 for him, to be paid in three equal annual instalments. Otho landed at Nauplia on the 31st January 1833, attended by 3600 Bavarian soldiers, and was warmly welcomed by the people. The French troops had been gradually reduced, and were now entirely withdrawn. The regency commenced the work of organizing the government, made a new division of the country, disbanded the palikars, formed a small body of Greek regulars, and took some steps towards the establishment of tribunals. As might have been expected, its endeavours to introduce order soon awakened the factious spirit of the klephts or military chiefs, some of whom, including the arch-anarchist Colocotroni, were tried for plotting the overthrow of the government, convicted, and sentenced to imprisonment or exile.

(The preceding narrative, as far as the end of 1827, is abridged from Mr Gordon's *History of the Greek Revolution*, Edinburgh, 1832; an able, impartial, and instructive work.)

In the whole course of the war, the Greeks never had any regular army; for the attempts to form a corps of disciplined troops, and keep them in pay, always failed. Their soldiers, with the exception of some small bands of Armatoles, consisted of peasants who took up arms for a few months, when the enemy made an irruption, and fought till he was expelled, or driven into the fortresses. They made war as irregulars, seldom encountering the Turks in the field, but posting themselves in defiles, and on mountains, taking advantage of rocks, inequalities of the ground, villages, or ruined buildings; and where these were wanting, covering themselves by small temporary parapets of earth or stones, called Tambourias. The Rumeliots were excellent marksmen, and admirable at defending a post. A hundred of them planted in a ruined monastery seldom failed to beat off one or two thousand Turks. Their defeats were chiefly owing to three circumstances: first, their entire want of cavalry—for as infantry they were superior to their enemies; secondly, their deficiency in artillery, both for service in the field, and for battering fortified posts; thirdly, their incorrigible neglect of order and discipline, in consequence of which they were often surprised and routed by a contemptibly inferior force. As obstacles to their success, we must also mention their mutual animosities, the rapacity and selfishness of their chiefs, and their habit of neglecting all advantages for the acquisition of spoil. Their fleet was better managed than their army, but its operations failed on many occasions, from the mutinous spirit of the sailors, and the habit, which they could scarcely ever be persuaded to abandon, of returning to port to see their families at the the end of every month, however pressing might be the occasion for their services. With all their faults and errors, it is impossible to read the history of the revolution without feeling respect for their courage, and for the unconquerable spirit which bore them up under the most dreadful privations and reverses.

In June 1835 King Otho assumed the reins of government, in which he was assisted by a council of state, nominated by himself. The whole territory was divided into communes of three classes: the first, those containing a population of 10,000 and upwards; the second, those from 2000 to 10,000; the third, of less than 2000. The communes of the first class were governed by a demarchos or mayor, 46 paredroi or aldermen, and a municipal council of 18; the smaller communes, by a demarchos, with proportionably fewer aldermen, and a less numerous council. The election of the municipal officers was vested in the male inhabitants above 25 years of age, and every commune was responsible for the acts of violence and robbery committed within its jurisdiction.

So necessary was repose to all classes of the people after the ravages of a long war, that the first years of Otho's reign passed in comparative tranquillity, although the sullen murmur of discontent was frequently heard, especially with reference to the state appointments, which were filled by the king's German friends, to the exclusion of the native Greeks. Otho refused to establish a representative system of government till September 1843, when the people rose and accomplished a revolution which has hardly any parallel for the skill and success with which it was executed. There was neither bloodshed nor violence, nor was the personal safety of the king in anywise endangered. But the plans being matured, and the army gained over, the ministers were arrested, and the people, assembling in front of the palace in the middle of the night, demanded a constitution. The king appeared at a low window, and they presented to him a charter including a representative government and other popular objects, and enforcing the dismissal of the Bavarian and other foreign officers. The king was required either to sign this charter or to quit the shores of Greece at once and for ever, in a vessel which had been equipped, and was lying ready for his embarkation. At first he promised to consider the demand and consult his ministers; but he was informed that the ministers were no longer recognised, and that an immediate decision was necessary. The king now acceded with as good a grace as he could; the obnoxious ministers were released, and the new ministry, selected by the constitutionalists, repaired to the palace, where they afterwards appeared with his Majesty on the balcony, while the people cried "Long live the constitutional King;" and the affair terminated apparently to the satisfaction of all parties. It is said, however, that before long the constitution had become a veritable farce, the deputies being in every case direct nominees of the king, and military force being employed, when necessary, to carry the candidate of the government. Not only the chambers, but the whole civil and military administration, had become little else than a refined system of corruption. The judges likewise, the professors of the university, and the masters of the gymnasia and inferior schools, fell under the unlimited control of the government, being all removable at pleasure.

The only subsequent events of general interest have been the interventions of foreign powers, rendered necessary by the duplicity of the government. The first of these was in 1850, when a British fleet blockaded the Greek ports for three months before the government would consent to compensate certain British subjects for injuries which had been inflicted on them. The other interference occurred at the commencement of the war between Turkey and Russia in 1854. In order to understand this movement, it is necessary to remember that two passions are predominant in the Greek mind—implacable hatred against the Turks, and an ardent desire to extend the kingdom of Greece. These feelings, which animate every Hellenic breast, received a further impulse from the consent of the king. On this subject foreign political opinions were divided as to whether the revolution was of Russian instigation. That the mass of the people believed in Russian assistance, and also that, through her influence, they would acquire an extension of their territory, there is no doubt; but we believe that the higher classes in Greece would not have advised such a revolution had they been at all aware that the Western Powers would have taken arms against Russia. They cannot be accused for their miscalculations, because higher authorities in Europe could not believe in the war at that early period. Besides, they knew well enough that Russia urged them to rise several times in the last century against the Turks, and, after she had accomplished her designs, left them to the revengeful sword of their masters. They had, therefore, little confidence in her. But the time chosen was so propitious, that an impartial judge would have accused them of being apathetic if they had not arisen. There appeared also an adverse feeling towards the allies, because we were in the peculiar position as defenders of their implacable enemies; but they forgot that, in defending Turkey, we served their interests by keeping their inheritance intact, out of the reach of the powerful hand of Russia.

We are of opinion, therefore, that the Greek nation has no sympathy with Russia more than with any other people who would make war against Turkey; and we believe, that if to-day we were to proclaim war against Turkey, there would be little necessity for sending our soldiers there, inasmuch as it would be sufficient to raise the standard of liberty for the Greek race, and we should have round us in a few weeks 100,000 well-armed Greeks, needing little more than ammunition.

The accusation, therefore, heaped upon the Greek nation, as being partizans of Russia, is unfair. Neither do we believe that either the king or queen of Greece stimulated the revolution to serve Russian interests. We cannot see what inducement they could have to endanger the throne they possess. Their ambition to extend their power was, we believe, the only reason; and how far that was their policy, and harmonized with the wishes of their subjects, is evidenced by the strong attachment towards them. The revolution, however, after the interference of the allies in favour of Turkey, was incompatible with their proclamation; and seeing that neither the revolutionists nor the king took heed of their advice, they were obliged to land some French and English troops at Piræus, and to send a few British ships into the Ægean.

The king was obliged to comply with their demands, dismissed his ministers, recalled his officers, issued proclamations to all Greeks that took up arms to return to their homes, and consented, on his own part, to submit the conduct of his government to the surveillance of the allies for a time. The ministers imposed upon him have been lately dismissed, and a new ministry formed, who conduct the affairs of the kingdom in a satisfactory manner. Severe measures have been taken against the scourge of the country—brigandage; and it is hoped that this time at least we shall see an end to their depredations.

It was only in 1816 that the first Greek house—E. Ralli and Co.—was established in London. In 1818 four more were established; and there are now 61 firms in London, 65 in Manchester, 30 in Liverpool, besides a few in Glasgow, and other parts of the United Kingdom. The statistics would be interesting if we could give an account of all the trade this small body of merchants is doing with this country and all other markets, but it is exceedingly difficult to get them. We only know that the exports of manufactured goods to Turkey in 1830 was L.1,028,447, whereas now it is above L.4,000,000, the increase of which is almost solely due to Greek enterprise.

The following statistics show that the progress which the Greek nation has made is highly creditable.

STATISTICS OF GREECE.

1. *Cultivated Land in* 1854.

	Stremata.		Stremata.
For Cereal	3,649,870	For Mulberry trees	240,000
... Olive trees	600,000	... Fig trees	150,000
... Vines	1,000,000		5,659,870

Cattle.

Sheep and goats	5,600,000	Mules	30,000
Oxen	160,000	Asses	7,000
Buffaloes	2,000

2. *Statistics of Silk.*

	Okes.	Drs.	Average price per oke.
1851	48,282	991,947	= 20·54 drs.
1852	60,771	1,999,970	= 32·91 ...
1853	56,770	1,774,063	= 31·25 ...
1854	—	1,353,018	
1855	70,000	—	

This proves not only an increase of production, but also an improvement in the quality; for, though the quantity has nearly doubled since 1851, instead of reducing the price, Greek silks are fifty per cent. dearer.

3. *Commercial Navy of Greece.*

	Vessels.	Tons.		Vessels.	Tons.
1821	440	61,449	1844	3414	146,703
1834	2891	—	1845	3584	161,103
1835	3370	—	1848	3983	255,233
1838	3269	88,502	1850	4016	266,201
1839	3345	89,642	1851	4327	257,093
1840	3384	110,690	1852	4230	247,661
1843	3469	137,558	1853	4143	247,991

We have no accounts of 1854; but there is no doubt it will show an increase on 1853, in consequence of the permission of the Czar for the Greek flag to enter the Danube.

4. *Population.*

1821	675,646	1852	1,002,118
1832	712,008	1853	1,041,527
1843	863,003	1854	1,142,227

5. *Imports and Exports of Greece.*

	Exports.		Imports.
1851	13,995,195 drs.	1851	—
1852	10,402,212 ...	1852	24,982,151 drs.
1853	8,988,890 ...	1853	20,209,960 ...
1854	6,799,211 ...	1854	21,270,182 ...

The minister of finance states that the great decrease in exports for the last three years is owing principally to the failure in the currant crops, the result of the disease in the vine.

Of the 13,995,195 drs. exported in 1851, 8,359,196 drs. were of Corinthian currants alone. In 1852 the exports of currants were 2,844,058 drs. only, or nearly six millions less than 1851; in 1853 there is no account of the currants exported inserted; and in 1854 only the small amount of 9046 drs. are included in the amount of 6,799,211 drs.

Judicial Statistics (1852).

Cases before the judges of the peace, 22,602, of which 4753 were amicably adjusted by the judges, it being their duty to conciliate the adversaries before bringing their dispute into court; and 1035 were carried to a superior court. The civil tribunals in the same year had 17,268 cases brought before them; but 2108 were left for decision in the following year. The court of the last resort, or Areopagus, had, in 1852, 702 cases; at the end of the year 55 were left undecided, 187 were abandoned by the parties, and 519 were decided.

GREEK CHURCH, The. Western Christendom has for many centuries been so much engrossed with its own concerns that it has paid little attention to the Greek Church, and knows little about the distinctive character or position of that large section of professing Christians. But recent events have rendered it necessary to give a somewhat more minute account of the origin, progress, and present position of the Greek Church than formerly.

Those who have paid attention to the effect upon human opinion of diversities in race and language, will be prepared to expect a considerable difference to appear in certain points between the churches of the Eastern and Western divisions of Christendom. In the Eastern division the chief seats of influence, from the earliest period, were Jerusalem, Antioch, and Alexandria. In the Western division Rome naturally obtained pre-eminence, as being the seat of imperial power, though not on account of any special right as a church. The peculiar claims of Alexandria arose out of the reputation which that city had obtained as a seat of learning and philosophy. Nearly all the doctrinal controversies which agitated the church for the first three centuries, were more or less directly connected with Alexandria; but while thus African as to their locality, they were Oriental in their real source and character. The tendency of the Oriental mind was very evidently displayed in its proneness to speculative inquiries into the spiritual mysteries and metaphysical regions of thought, and the dim theosophic mysticisms, which seemed to be connected with the great and primary truths of Christianity. On the other hand, the tendency of the Western mind to the steady pursuit of power, manifested the result of that training which the stern Roman republic and domineering Roman empire had given to Europe. It was not as having been the bishopric of the Apostle Peter, either in fact or in pretence, that Rome *at first* sought and began to acquire pre-eminence; but it was as the abode of secular dominion, the imperial city, in whose inhabitants ambition and love of power had become both a universal passion and an imagined right. The Eastern mind delighted in intellectual subtleties, and strove to gain the high position of supremacy in the regions of thought. The Western mind was characterized by a stern, invincible *will*, and sought the tangible dominion of absolute power and personal supremacy. These leading and characteristic distinctions may assist us in tracing the subject of investigation.

It was not till after Constantine the Great had resolved to raise Byzantium into the rank of an imperial city, to give it his own name, to divide the empire into two, and to make Constantinople the seat of the Eastern empire, that the characteristic distinctions already stated began to manifest their antagonistic tendencies. The Bishop of Constantinople became then the metropolitan in a second seat of empire, and ere long greatly absorbed the influence of the elder metropolitans of Jerusalem, Antioch, and Alexandria. The title of metropolitan was raised to that of patriarch in all these apostolic seats, as they were beginning to be termed, but still the seat of Eastern empire gave pre-eminence to the Patriarch of Constantinople above the other Eastern patriarchs.

At length the great barbarian invasion of Huns, Goths, and Vandals overthrew imperial Rome, and reduced it to a simple monarchy. This event gave opportunity to the Bishop of Rome to assume and exercise a large measure of civil influence and power. In him seemed to be vested the heritage of imperial Rome's fallen greatness; and on that very account the Western nations readily acceded to the Pope of Rome the pre-eminence which had been wielded by the previous emperors. The very name of Rome was still a word of power, a spell wherewith to evoke the demon of ambition, and the Pope was the mighty magician to whom alone that word of power belonged. The popes, as already remarked, seemed naturally to imbibe the spirit of ambition and love of power by which the haughty city had been so long possessed. They were, therefore, very ready to avail themselves of the opportunity thus presented; and as the empire passed away, the popedom arose, grew, and succeeded to all the proud pretensions of the imperial Cæsars.

In the meantime the Eastern seat of power, Constantinople, seemed to be, at least in secular affairs, the proper successor of imperial Rome; but in consequence of its position, it looked more like the successor of the empire founded by Alexander the Great. It began, therefore, to receive designations indicative of that position, and to be called the *second*, or the Lower Greek Empire. At a subsequent period, when the Eastern Church and the Western became separate, and hostile or rival bodies, the designation Greek Church, was given to the Eastern division, from that of Lower Greek Empire, which had become distinctive.

The ambitious tendencies of the Bishops of Rome were very early manifested. The first instance of that arrogance which produced a general disturbance in the church, and introduced the element of strife, causing a permanent difference, was that respecting the celebration of Easter. The Oriental churches followed the reckoning of the Jews as to the time of the Passover. The Western or Latin Church adopted a different computation. In the year 196, Victor, Bishop of Rome, addressed a letter to the Asiatics, expressly commanding them to conform to the practice of Rome. They convoked a synod, deliberated on the question, and refused to comply. Victor issued an edict of excommunication against the Oriental churches, which they indignantly repelled. The assumption of supremacy thus displayed by Rome was not admitted by the rest of the Christian Church; but neither was it withdrawn by Rome. Roman ambition appeared in the attempt repeatedly made by successive Popes to claim the right of ultimate jurisdiction, by having it conceded that in difficult or disputed cases there should be an appeal to Rome. This claim was, of course, favoured by parties who thought themselves injured, or who, in their desire to gain some peculiar point, sought the support of Rome—a support which she was willing to grant to any case, provided she could thereby obtain confirmation to her claim of appellate jurisdiction.

Early in the fifth century, the metropolitan jurisdiction of Constantinople was considerably extended, and the jealousy of Rome thereby excited. This was greatly increased when, in 451, the council of Chalcedon conferred on the Bishop of Constantinople the same honours and privileges which were already possessed by the Bishop of Rome, notwithstanding the strenuous opposition of Leo the Great, who was at that time Pope. Leo perceived very clearly the advantage which the rival pontiff enjoyed from the residence of the emperor; and to counteract that influence he appointed a resident legate in Constantinople to watch over the Papal interests, and to maintain a constant correspondence with the Vatican. The contest continued for nearly a century and a half, keeping the whole church in a state of incessant intrigue and agitation—the advantage on the whole inclining to Rome, chiefly in consequence of the ready countenance and support which the Popes gave to the discontented and turbulent who sought her aid, and thereby strove to strengthen the claim to appellate jurisdiction, in which supremacy was necessarily involved. In the year 588, in a synod held at Constantinople, John the Faster, Patriarch of Constantinople, adopted the title of UNIVERSAL BISHOP, a title which was vehemently condemned by Pope Gregory, although it does not seem to have been intended to confer any authority by that title at first, but to be merely an empty honour. In the possession of a Patriarch of Constantinople it could not indeed, confer power; because the emperor himself always contrived to retain all power, even ecclesiastical, in his own hands. The result was very different when the same title was conferred on the next Pope, Boniface III., by the emperor Phocas in 606, which no subsequent emperor could recal, nor in any great degree control, in consequence of the independent position and residence of the Popes.

The contest for supremacy which had so long been waged between the Eastern and Western Churches, became at length a schism, in consequence of the introduction of a *doctrinal element* into the dispute. The most important doctrinal controversies which agitated the early church were those relating to the doctrine of the Trinity. The Arian heresy was a denial of the divinity of Christ. This was condemned in the council of Nice in 325. The divinity of the Holy Spirit was also disputed, but was affirmed in the council of Constantinople in 381, when also the *Nicene Creed* was revived and enlarged, so as to contain a clear statement and definition of the faith of the church. In that creed, so revived and authenticated, the definition of the Holy Spirit contained the words "proceeding from the Father." But at the council of Toledo, held in 447, the following words were added, "and the Son" (*Filioque*) so that the definition became, "proceeding from the Father and the Son." This clause did not attract much attention for some time; but when it did, it was immediately opposed by the Greek Church. It was, however, favourably received by the Western Church; was affirmed by a council held at Gentilli, near Paris, in 767; and was re-affirmed at the council of Aix-la-Chapelle in 809, where Pope Leo III. admitted the truth of the doctrine, but objected to making it an article of faith. Rome, however, soon adopted the expression; and in order to defend it by authority, falsified the canons of the council of Constantinople by interpolating the very clause in dispute. This was of course easily detected, and added greatly to the bitterness of the controversy. But Rome adhered to the favourite maxim of Papal policy, *never to retract any statement or assumption however false;* because answers and refutations may be forgotten, but the incessant repetition of the false statement will finally lodge it in men's minds, by the mere force of iteration and re-iteration.

Some time after the rise of this controversy, a person of the name of Photius, a layman of great learning and ability, was made Patriarch of Constantinople by the Emperor Michael, who deposed Ignatius to make room for Photius. The deposed Patriarch appealed to Rome. Pope Nicholas assembled a council at Rome in 862, pronounced the elevation of Photius illegal, and excommunicated him and all his supporters. Photius retaliated, held a council at Constantinople, and pronounced deposition and excommunication on the Pope. From that time the contention between the Roman and the Greek Churches may be fairly said to have assumed the character of a schism; and, indeed, it is called by Romanist authors the Photian schism. But there was another event at a later period from which the actual schism is more commonly dated. About the middle of the eleventh century, when the power of Rome had been established over all the Western Churches, ambition urged on the proud claim of the Pope to universal supremacy; and Leo IX. attempted to induce the Patriarchs of Alexandria and Antioch to submit to his sway. This drew forth the indignant opposition and remonstrances of Michael Cerularius, Patriarch of Constantinople; and after some angry correspondence with Rome, the Pope pronounced on him the sentence of excommunication. This was not at once final. The Papal legates were invited to Constantinople, with a view to heal the schism; but their insolence provoked severe retorts. The breach widened; and, at length, in the church of St Sophia, they publicly excommunicated the Patriarch and all his adherents, deposited their written sentence on the great altar, shook off the dust from their feet, and departed. This event took place on the 16th of June 1054; and the schism between Rome and Greece was completed.

From that time forward the Greek and Roman Churches have continued in a state of separation from each other, and generally in a state of considerable hostility. One attempt to obtain a reconciliation between them was made at the council of Florence in the year 1438. At that time the Greek Patriarch and his friends seemed disposed to concede almost everything in dispute for the sake of a re-union with Rome. Constantinople was then violently assailed by the Turks; and as the Greek empire was not able to resist the formidable enemy, the idea was entertained of attempting to organize a new crusade for its relief. But great as was the political danger, greater still was the ecclesiastical rivalry; and although the parties who attended the council at Florence would have yielded everything for the sake of a crusade, the Greek Church as a body was not disposed to ratify such extensive concessions, and the attempt proved abortive. The Greek Church would not admit the insertion of the *Filioque* clause, nor the supremacy of Rome, and nothing less could satisfy Rome. At a later period, when the Reformation had shaken the power of Rome in Europe, she was inclined to adopt a more conciliatory course with the Greek Church, and seemed really desirous of reunion. But it may easily be perceived that no such union is practicable, unless the Greek Church submit to the supremacy of the Pope, which is not only a necessary principle, but *the* necessary principle with Rome. And, as the *Filioque* clause is inserted in the creed of Rome, it also must be admitted by the Greek Church, and with it every other Papal innovation. This would not be union, but absorption—the extinction of the Greek Church, and the extension of Papal Rome.

But there is another element of a very formidable character which has greatly increased the impracticability of such a union or absorption. Christianity was introduced into Russia from Constantinople about the year 866. The Church of Russia thus received its creed and ritual from the Greek Church before the schism between the Greek and Latin Churches had been consummated, yet so near the period of that schism as to receive with its creed a dislike to Rome. During several centuries the Russian Church was governed by a metropolitan bishop, whose seat was successively at Kieff, Vladimir, and Moscow. At length, in 1589, the Patriarch Jeremiah of Constantinople, on whose patriarchate the Russian Church had been dependent, went to Moscow, and consecrated the metropolitan bishop, Job, to the rank of Patriarch of all Russia. From that period the Church of Russia ceased to be dependent on the Greek Patriarch, though it continued to be identical in doctrine and ritual with the Greek Church. This was in many respects a very important event. The Lower Greek Empire had been overthrown when Constantinople was taken by the Turks in 1453. From that time forward, although the Patriarch of Constantinople was allowed by the Sultan to reside in that city as the official head of the Greek Church, yet his power and influence had undergone a sad decline. It was no longer possible that he could exercise much authority in the East, or maintain Christianity against the sway of the haughty Moslem. In the meanwhile Russia, relieved from the Mongolian domination, had begun to emerge out of barbarism, and to assume the position of an independent and growing power in the northern regions of both Asia and Europe. All the other Oriental patriarchates had also fallen under the Mohammedan power. Alexandria, Jerusalem, and Antioch were little more than names, once venerated, but now sinking into oblivion. If, then, the Greek Church was to continue in the enjoyment of an independent existence, that was possible only by its seat of power being transferred to Russia. And when so transferred, it became possible not only that its independent existence could be prolonged, but that as the church of a great and rapidly-increasing nation its own influence might also increase.

There was still another change awaiting the Greek Church in Russia. The patriarchate had continued for little more than a century, when, on the death of the tenth Patriarch, Adrian, in the year 1700, a new crisis came. The sceptre of Russia was at that time swayed by the vigorous arm of that sublime barbarian Peter the Great. The genius of that marvellous man was set on the vast achievement of raising Russia at once to the rank of a great and even of a civilized power. For the accomplishment of such an enterprise, the possession of all power, civil and ecclesiastical, in the most absolute form, was necessary, that he might, by his sole unfettered energy, do the work of centuries in a lifetime. He prevented the election of another Patriarch, made himself head alike of both state and church, and appointed Stephen Yavorsky to the nominal rank of *Guardian of the Patriarchate.* Through this novel agency he ruled the church at his will, as he was also ruling the state. Finding a little disposable leisure in the year 1721, Peter set himself to frame a new constitution for the church. He constituted a supreme court for its government, called the MOST HOLY SYNOD, of which he appointed himself president, and delegated a procurator to occupy his position in his absence, without whom no meeting of the synod could be held, and without whose consent no decision could be valid. Since that time the emperors of Russia have held the most absolute supremacy over the Church of Russia. It may be added, that as the Greek Church has no means of maintaining its independent existence in either Papal or Mohammedan countries, but must look to Russia as the only powerful country that adheres to its faith, the Russian autocrat may be said to hold the most absolute supremacy over the Greek Church wherever it exists, or at least to be naturally regarded as its protector.

From this historical survey we can mark the relations of the Greek Church to other Christian churches. Its relations to that of Rome may be very easily seen and understood. Till the period of the fifth century there was no other essential ground of difference between them than what arose from their conflicting claims of supremacy. In doctrinal matters they were nearly identical. They had not borrowed from each other, but both held the doctrines which had been declared by the general councils. From that position the Greek Church has scarcely moved. An accurate knowledge of the doctrines and ritual of the Church in the FIFTH CENTURY will therefore adequately represent and explain all that is common to the Churches of Greece and Rome. The schism which took place at a later period has rendered the Greek Church a standing testimony against Rome with regard to the subsequent errors and corruptions of that rival system—a testimony with which Papal controversialists find it very difficult to deal.

The controversy between the Greek Church and Rome must needs be interminable as a ground of separation, unless Rome renounce her claims both of universal supremacy and of infallibility,—that is, unless she cease to be Papal; or unless the Greek Church submit so entirely to all the claims of Rome, that she would cease to have any independent existence. But, still more, the position which the Greek Church so long held, as independent of Rome, was almost entirely the result of its direct connection with the Lower Greek Empire, and its dependence upon the emperors. Throughout all the period of its existence the Greek Church has been subservient to the civil power. Its elevation to patriarchate dignity was due solely to its connection with the seat of empire. Its Russian branch obtained similar rank in consequence of the rise of Russia into a great monarchy. The absorption of all ecclesiastical power by the state under Peter the Great, though placing it in a condition of greater subserviency than it had ever before experienced, was nevertheless only the extreme development of its hereditary servitude. It is not, therefore, now in the power of the Greek Church to unite with Rome without the permission of the Emperor of Russia. The memory of her former intercourse with Rome can have left no such favourable impression on Russia as to make her willing to resume it. About the year 1590, Ignatius Potsi, Bishop of Vladimir, commenced a series of intrigues for the purpose of effecting a union between the Russian Church and that of Rome; and, in 1596, a strong party was formed in the Polish and Lithuanian provinces, termed Uniates, from their support of the proposed union, whose adherents soon amounted to four millions. Every effort of force, fraud, treachery, and rebellion—all that Jesuits could suggest, and traitors accomplish—was tried by the Uniates for many years, causing incessant turmoil and bloodshed in the large district which they inhabited—making Lithuania an Ireland to Russia. This continued till so recent a period as the year 1839, when three millions of the Uniates were reconciled to the Russian Church, to the great delight of the Emperor Nicholas. The sufferings inflicted on the nuns of Minsk may testify by what peculiarly Russian persuasives this reconciliation was effected. It may be very confidently believed that there is not the slightest probability of any cordial agreement between the Roman Church and the Russian element, now the ruling one, of the Greek Church.

There is one other point to which reference may be made, rather as a matter of curiosity than on account of its public importance. About the year 1723 there was a proposal made by certain Anglican bishops respecting the possibility of union with the Greek Church. But when the creed of the Church of England was examined, it was found to be far too deeply imbued with the principles of the Reformation to suit the views of the Eastern Church; and though there was no formal rejection, the proposal was laid aside. It is of some interest also to know that similar notions about a possible union with the Greek Church have been promulgated by certain Puseyite clergymen at present. Their attempt, it may be anticipated, will prove equally abortive, though it may somewhat embarrass British statesmen.

The chief points of difference between the Greek Church and that of Rome are the following:—The Greek Church does not admit—1. The supremacy of Rome. 2. The *Filioque* clause in the creed. 3. The enforced celibacy of the parochial clergy; though monks and bishops must be unmarried. (The reason of this is, that although the monastic system had begun before the schism, the celibacy of the regular clergy had not been enforced till a later period, and this was not adopted by the Greek Church.) 4. The doctrine of transubstantiation, in the Papal sense of that term, is not held by the Greek Church. (Rome itself did not adopt this strange tenet till the council of Lateran in 1215.) 5. The dogmas of purgatory and penance, as taught by Rome, are not held by the Greek Church; yet some of their views bear a close resemblance to the Papal theories on these points. 6. The Greek Church disagrees with that of Rome about the use of leaven in the Eucharist. In almost all other respects there is little difference between the Greek and Roman Churches, because both are as corrupt as the church of the fifth century, and both have hitherto rejected the Reformation. The Greek Church is thoroughly hierarchical; holds the monastic system; worships pictures, although it rejects the worship of images; gives to the Virgin Mary as high a degree of worship as even Rome can—its theory of the Panagia being scarcely distinguishable from that of the Immaculate Conception.

The following inferences, of some importance in the present state of European and Eastern affairs, may be fairly drawn:—1. The Greek Church cannot unite with Rome, in consequence of Rome's claim of supremacy, and the hereditary rivalry of the two on that point. 2. The Greek Church cannot submit to Rome, because the ecclesiastical supremacy of the Emperor of Russia is the exact counterpart and express antagonism of the Pope. 3. The errors which the Greek Church holds in common with Rome are not derived from Rome, but are those common to the whole church in the fifth century. 4. The Greek Church could become Protestant, because it never has denied, and cannot, consistently with its own creed, deny, either the authority or the free circulation of the Scriptures. 6. One single Christian-minded and wise Russian emperor could place the Greek Church in Russia in friendly relation with evangelical Protestantism, which, indeed, the Emperor Alexander I. seemed inclined to do. Even in Russia there is one element looking in that direction, namely, the *Starowers*, or *Starovertze*, or "Old Believers," who dissent from the doctrine of *Imperial Supremacy*, and are active in diffusing the Bible. That body amounts, it is said, to about five millions of native Russians. They are, however, discountenanced, depressed, and to some extent persecuted by the Czar. But although there is no necessary antagonism between the Greek and Protestant Churches, yet the Greek Church hates, opposes, and persecutes Protestants, so far as it can.

The Greek Church bears, in its organization and external forms, a very close resemblance to that of Rome, as might be expected from their mutual origin in the corrupt Christianity of the fifth century. The Patriarch of Constantinople was the virtual Pope of the Eastern Church till the taking of Constantinople by the Turks, with this special difference, that the Patriarch was never allowed to exercise any civil authority. Since that period the Sultan has allowed the existence of the Patriarch, and recognised his religious superiority over those of his own creed; but has himself held the power of appointing to, or deposing from, that office, for which he exacts a tribute or purchase before investiture. Archbishops and bishops also are required to purchase their official dignity by the payment of a tribute to the Turkish government. The officiating clergy of the Greek Church are the Patriarch, archbishops, and bishops, and subordinate to these are the papades or parish priests. All the dignitaries are taken from among the caloyers or monastic orders, and are not allowed to marry; but the papades may be married, with these special limitations—that they be married previous to their consecration, and may not marry a second time, should they become widowers. Hence they are commonly married before taking orders, and invariably select young and healthy women for their wives. The revenues of the dignitaries are raised by a tax imposed on each family, while the parish priests are supported chiefly by means of what they can wring from the superstitions of the people as perquisites of office, such as money paid for absolutions, benedictions, exorcisms, ceremonial sanctifyings of water, sprinklings of streets and tombs, granting divorces, and innumerable ritualistic observances. They are almost universally a base and degraded class themselves, extremely ignorant, and they keep the people in equal degradation and ignorance, partly because such is their own state, and partly that they may secure their influence.

Their places of worship are built generally in form of a cross. The choir is always placed towards the east; and the people turn their faces in that direction when they pray. Their public religious service is liturgical and exceedingly protracted. They have four liturgies; and the service consists chiefly of prayers, hymns, recitative chants, and frequent crossings, with such numerous repetitions that it often occupies five or six hours, without any sermon. During this long service the people stand leaning on the supports of the few seats in the church, or on a kind of crutches provided for that purpose. No images are allowed within their churches; but they are plentifully decorated with rough and glaring paintings, and the more rough and glaring these are, the better are they in the estimation of the worshippers. Their music is without any aid from instruments, and is chiefly a kind of chanting, but is said to be often beautiful and touchingly plaintive, although monotonous. The vestments of the clergy are very varied in form, and often of fine texture, gorgeous in colour, and ornamented with jewellery of great value. Each of these vestments has its mystic meaning and virtue, to which great importance is attached. The worship of saints, angels, and the Virgin Mary is carried to as great an excess as it can be at Rome; and it is long since the Greek Church held that the "Mother of God," as they term her, was without original sin. It may be said, indeed, that the *Panagia*, or Holy Virgin, is the peculiar deity of the Greeks, as much as ever Pallas Athene was of the ancient Athenians. Everywhere, in church, palace, or cottage, a little coarse picture, intended to represent the Holy Virgin, may be seen, often with a lamp burning before it as the object of special adoration.

The Greek Church is also burdened by an immense number of fasts and saints' days. The secular Greeks observe four Lents, and the caloyers or monks, two more. The first of these lasts two months, the second forty days, the third is variable, and the fourth continues from the 1st of August till the festival of the Assumption, on the 15th. All Wednesdays and Fridays are fasts, and a vast number of saints' days are also observed, so that of the whole year there are only about 130 days free from fasts or festivals, by means of which the common people are either crushed into idleness and poverty, or rendered regardless of religion.

The Russian division of the Greek Church has nearly absorbed the whole, so far as regards its relation to other communities. The Patriarch of Constantinople has long been dependent on the Sultan. The Patriarch of Alexandria is obeyed by only two churches. In Antioch the adherents of the patriarchate can be all accommodated in a single room in a dwelling-house. The Patriarch of Jerusalem resides chiefly at Constantinople, and owes any power he possesses to the holy places held by Greek monks in Palestine, which the Romanists, by means of a French agent, recently attempted to seize, an attempt which tended to precipitate the present war, in consequence of the intervention of Russia as the avowed protector of the Greek Church.

An approximation is all that can be made towards an estimate of the numbers adhering to the several divisions of the Greek Church; and in this we follow Marouvieff and Neale,—chiefly the latter, as the most recent authority.

In Russia	50,000,000
In Turkey	12,000,000
In Greece, Montenegro, &c.	800,000
In the Austrian dominions	2,800,000
In the Patriarchate of Alexandria	5,000
In Asia Minor and Cyprus	150,000
In the Patriarchate of Jerusalem	15,000
Total, about	65,770,000

Of these, as will be seen, at least 50,000,000 belong to Russia alone, forming the only division of this ancient nominally Christian Church, which has now any degree of power for good or evil, and possessing that power only as the Russian autocrat may please to permit, or may think proper to employ it, as an engine of despotism. The jurisdiction of the Patriarch of Constantinople extends nominally over the Greek Church in Turkey, Sclavonia, Galicia, Anatolia, and the Ionian Isles; but his influence has sunk to the merest semblance of power in all these countries. In Servia the metropolitan Bishop of Belgrade maintains an independent authority. There seems no probability that the Greek Church, either in Turkey or Asia, can again be united under one Patriarch, so as to become active and powerful; and it may be hoped the course of modern events will so protect and encourage the progress of a sound and free Bible Christianity, as to rescue from superstition, enlighten, and elevate the inhabitants of that lovely and fertile region of the earth, the ancient home of freedom, and closely connected with the birth-place of true religion. (W. M. H.)

GREEK FIRE. See FIRE, *Greek.*

GREEN, one of the prismatic colours. It is composed of blue and yellow rays, which, mixed in different proportions, exhibit various shades.

GREEN BAY, a large arm or bay on the west side of Lake Michigan, forming a part of the boundary between Wisconsin and the upper peninsula of Michigan. It is above 100 miles long, and from 15 to 35 broad. The epithet "Green" has been applied to it on account of the colour of the water, which is said to exceed 500 feet in depth. At the head of the bay, on the right bank of the Neenah, or Fox River, is a thriving town of the same name. The bay and river afford a perfectly secure harbour, and the largest steamers of Lake Michigan stop here, making it the principal place of deposit and transit for the imports and exports of Northern Wisconsin. Pop. (1853) about 2500.

GREENCASTLE, a flourishing post village, capital of Putnam county, state of Indiana, North America. It is on the great line of railway extending through the centre of Indiana from east to west; and another line of railway is in progress which will cross the former at Greencastle, and connect it with South Chicago and with the Ohio River at New Albany. It is the seat of Asbury University, a flourishing institution belonging to the Methodists, and has several high schools. Pop. (1850) 1382.

GREEN CLOTH, BOARD OF. See HOUSEHOLD, *Royal.*

GREENE, ROBERT, a dramatist and prolific miscellaneous writer of the latter portion of the brilliant Elizabethan era, was a native of Norwich, and born about the year 1560. He graduated in St John's College, Cambridge in 1578, and took his degree of M.A. at Clare Hall in 1583. Subsequently, in 1588, he seems to have studied at Oxford. From the period of his leaving Cambridge his life was that of an author by profession, marked no less by the extraordinary fertility of his talents than by the profligacy of his conduct, of which he has himself left many curious and affecting records. Of the forty or fifty plays, pamphlets, and poems of Greene which have come down to us, a few of his pieces are interesting as specimens of dramatic blank verse, and as illustrating the state of the English stage at a time contemporary with, or immediately preceding, the early dramas of Shakspeare. Greene was destitute of the fire and energy of genius, but he had a fine play of poetical fancy and command of classic imagery, with a smooth and copious diction, and considerable powers of invention. The true dramatic power, as evinced in the delineation of character and in depicting contrasts of situation and passion, he certainly did not possess, nor was there any approach to this on the stage before Shakspeare, excepting in the case of Marlowe. Greene's tragedy of *Orlando* has, however, many striking and elegant passages, and in his light comedies are scenes of low humour, interspersed with descriptions of English rural life and scenery. The play of *George à Greene, the Pinner of Wakefield*, doubtfully ascribed to Greene, introduces us to the forest scenes of merry Sherwood, to Robin Hood and Maid Marian. His numerous pamphlets throw light on the manners of the times, besides detailing his own adventures, knaveries, follies, and repentance. But the most popular of his works are those which borrow a lustre from their connection with Shakspeare. His tale entitled *Pandosto, or the Historie of Dorastus and Fawnia*, is memorable as the story on which Shakspeare founded his delightful drama of *The Winter's Tale.* The original story was published in 1588, and was so popular as to have gone through thirteen editions before 1632, when a fourteenth was printed. Shakspeare followed closely the outline of Greene's novel, excepting in the miraculous last scene where Hermione is restored. The geographical blunders of making Bohemia a maritime country, and placing the temple of Apollo at Delphi in an island, were copied from his prototype, as in *As You Like It* the poet placed a lioness in his forest of Arden, because he found a lion in Lodge's *Euphues,* whence he derived the groundwork of his play. Such anachronisms are common in the old dramatists and romance writers. Their fabulous stories are quite removed from the region of the literal and possible, but geographical blunders may perhaps be ascribed to ignorance and haste. It must be regarded as one of the idiosyncracies of Shakspeare's mighty mind, that one so boundless in knowledge, and so illimitable in his intellectual resources, should have had recourse to obscure writers and legends for the plots of his dramas. But no one, as Coleridge has remarked, can understand Shakspeare's superiority fully "until he has ascertained by comparison all that he possessed in common with others of his age, and has then calculated the surplus which is entirely Shakspeare's own." In the *Winter's Tale* the fascinating character of Perdita, the humour of Autolycus, and the exquisite sheep-shearing scene, are Shakspearian creations—and among his very finest.[1] To pass from the drama of Greene, Peele, Lyly, and Marlowe, into the drama of Shakspeare, is to pass into a new world. Characters, blank verse, language, sentiment, and action—all are different, and all new.

> "Changed like the world's great scene, when without noise
> The rising sun night's vulgar lights destroys."

In his latest work, *A Groat's-worth of Wit bought with a Million of Repentance*, Greene makes a well-known allusion to Shakspeare of the highest interest and value as connected with Shakspeare's dramatic progress. He addresses those gentlemen, "his quondam acquaintance, that spend their wits in making plays," and tells them "there is an upstart crow beautified with our feathers, that with his *tiger's heart wrapt in a player's hide*, supposes he is as well able to bombast out a blank verse as the best of you; and being an absolute *Johannes Fac-totum*, is, in his own conceit, the only *Shake-scene* in a country." There is no mistaking this reference; and the words "tiger's heart," &c., are a parody upon a line in an old play, the *True Tragedie of Richard Duke of York*, which line, with many others in the same old drama, Shakspeare adopted in his Third Part of *King Henry VI.* The obvious inference is that Greene, or some of his "quondam acquaintance," the makers of plays, was singly or jointly author of the *True Tragedy*, which Shakspeare had altered and adopted for his own theatre. Greene's *Groat's-worth of Wit* was published late in 1592 immediately after his death; at this time, therefore, Shakspeare appeared to his rival dramatist an "upstart," who had recently shot up into public notice, and commenced his career by remodelling and improving inferior and old plays. How he "bombasted out a blank verse" we all know, but the verses so written before September 1592 cannot now be ascertained. The questions, What were the plays? and How much in them was original? start to the mind; but as yet there is none to answer. If Greene could be proved to be the author of the *True Tragedy* and the *First Part of the contention betwixt the two famous houses of York and Lancaster*, which Shakspeare also remodelled, his character as a dramatist would be materially advanced. But they seem to us much beyond the pitch of Greene, and have more of the manner of Marlowe. The tragedies of *King John* and *Henry V.* are also founded upon old plays; and Greene, or some of his associates—Marlowe, Peele, Lodge, and Nash—may have written them. The charge of plagiarism is at all events distinctly brought forward—the great dramatist was "beautified with some of the feathers" of his contemporaries; but we must always recollect that it was Shakspeare's original editors that claimed for him the undivided authorship of the historical plays, not the poet himself. His dramas "*outlived him*," as Heminge and Condell finely remark in their dedication, "*he not having the fate, common with some, to be executor to his own writings*." If the *Winter's Tale* could be proved to have been produced before 1592, Greene's charge against Shakspeare would be easily understood; but all the evidence, internal and external, shows that it was a much later production. The point, therefore, must remain in obscurity; and however interesting it may be to curious investigators, it does not weigh one straw in the balance as respects Shakspeare's genius or fame. Greene died in great misery on the 3d of September 1592. At a supper the previous month, in company with Nash and some others of his associates, he had indulged to excess in pickled herrings and Rhenish wine, which brought on an illness that proved mortal. According to Gabriel Harvey, all Greene's gay companions forsook him in his last sickness, and he was maintained by a poor cordwainer and his wife in their house near Dowgate. This humble pair supported and nursed the miserable poet, decked his corpse with a garland of bays, *pursuant to his own request*, and paid ten shillings and fourpence for his winding sheet and burial. There is nothing in Greene's plays so impressive or dramatic as this last scene, nor anything more strange than the combination which his life presents of incurable folly, meanness, and vice, united to great literary industry. His associates did not benefit by his example; some of them sank under personal irregularities in early manhood; and it is lamentable to see how little classic acquirements and university honours, with all the aids of genius and popular favour, could effect in elevating the tastes and habits of these men, or saving them from the lowest moral degradation. (R. C—S.)

---

[1] Greene's reputation for scholarship—one who had "two gowns," like Dogberry, being master of arts in both universities—no doubt led Shakspeare to follow him in his geographical and classical allusions. In the *Pandosto* Greene makes Dorastus excuse his shepherd's disguise in this pedantic style:—"Shame not at thy shepherd's weed. The heavenly gods have sometimes earthly thoughts. Neptune became a ram, Jupiter a bull, Apollo a shepherd; they gods, and yet in love." Shakspeare thus paraphrases the passage:—

> "The gods themselves,
> Humbling their deities to love, have taken
> The shapes of beasts upon them: Jupiter
> Became a bull and bellow'd; the green Neptune
> A ram and bleated; and the fire-robed god,
> Golden Apollo, a poor humble swain
> As I seem now."

GREENHOUSE, or *Conservatory*. See HORTICULTURE.

GREEN MOUNTAINS, a mountain range of North America, commencing near New Haven in Connecticut, and extending through Massachusetts and Vermont into Canada. It attains its greatest elevation in Vermont, to which it gives name (*verts monts*, i.e., green mountains). Mansfield North Peak, the culminating point of these mountains, rises to the height of about 4300 feet above the level of the sea.

GREENLAND.

GREENLAND, or GROENLAND, a very large island, or, probably, assemblage of islands, lying to the north-east of North America, and for the most part comprehended within the Arctic Circle. In early times it was supposed to form a part of the American continent; but the discoveries of modern navigators have proved, what indeed the very idea of a north-west passage from the Atlantic to the Pacific Ocean supposed, its insularity. And the latest discoveries have, moreover, shown, or all but proved, the entire separation of the lands on the west side of Baffin's Bay, or rather, what we would now venture to designate *Baffin's Sea*, from those of the opposite shores, so as to limit Greenland to the country on the eastern side of that great channel. From Cape Farewell, in lat. 59° 49′ N., it stretches on the west side in a north-north-westerly direction through Smith's Sound, and then more easterly into a high northern latitude. On the other side, the Greenland coast runs first north-north-easterly, then north-easterly, and finally (so far as yet traced), in a northerly direction, bending eastward in the 75th and 76th parallels of latitude. It expands from Cape Farewell, the southern point, up to latitude 70°, where it attains a width of about 600 miles, which is pretty evenly maintained to the northern extent of our researches on the eastern side. This side of Greenland has been denominated East or Old Greenland, the other West Greenland.

In general, the discoveries which have been effected in this quarter of the globe have resulted from attempts made to discover a north-west passage to India through the Arctic Sea. The existence of such a communication is a subject which from time to time has occupied the attention of the British government for the last three centuries; and although much valuable information had been obtained by means of these voyages, the great problem remained unsolved until the very recent researches after the fate of our lamented voyager Sir John Franklin, when Capt. M'Clure, in his researches, *viâ* Behring's Strait, eastward, determined the fact of a sea communication between the Pacific and Atlantic Oceans. This he effected by sailing till within sight of Capt. Parry's discoveries at Melville Island, and thence completing the personal transit by ice-travelling and voyaging to the shores whence he had departed. But beyond the determination of the geographical fact, it was found, as had been confidently predicted, that no practical use could be made of a channel so thickly encumbered with impenetrable, or all but impenetrable ices.

Greenland was first discovered by an Icelander named Gunbiörn, who was driven by storm upon this coast, about the beginning of the tenth century, and carried back intelligence of its existence to Iceland. Towards the end of the same century,—according to some writers in 983,—an Icelandic chief named Eric Raude, or Eric the Red, having killed another powerful chief, and being obliged to quit the country, determined to follow up Gunbiörn's discovery. After having spent two or three years in exploring the country, he returned to Iceland, giving an exaggerated account of the freshness and verdure of the country, which he called Greenland. In consequence of this, a fleet of twenty-five sail was equipped and sent out, laden with persons of both sexes, cattle, and other necessaries for forming a settlement. Only about the half of the vessels reached their destination; but other adventurers setting out, not only from Iceland, but from Norway, the Orkneys, and other islands, in a few years a considerable colony was formed, and a regular trade established. The real position of these early adventures has been a subject of much learned investigation and no little controversy. But it seems highly probable that the original colony of Greenland began about the southern promontory, near Cape Farewell, and gradually extended itself along the coast in a north-westerly direction. Beyond this first settlement another proceeded farther to the west. The former was called *Œstre Bygd*, or the eastern settlement, and the latter *Vestre Bygd*, or the western settlement. Christianity having been introduced about the beginning of the eleventh century, numerous churches and convents were built, and the country was divided into regular parishes, to which monks and other spiritual instructors were attached. The colonists, although compelled to lead a life of severe privation and hardship, continued to increase, and to extend to the north. The zeal with which the early Scandinavians pushed their settlements to the northernmost parts of Greenland is strikingly attested by a curious monument which was discovered in 1824. It consists of a stone carved with Runic characters, which was found standing erect in the ground on the island of Kingiktorsoak, under the parallel of 73°.[1]

For some centuries the commercial intercourse between Greenland and Norway was kept up; but about the beginning of the fifteenth century all intercourse ceased, and the unfortunate colonists were cut off from the rest of mankind. The Esquimaux, the natives of the country, whom in derision the Norwegians called Scrœllings, or Dwarfs, on account of their diminutive stature, attacked the western colony, which was compelled to seek assistance from that which lay to the south-east. There can be little doubt that the scanty population was reduced by these savage invaders; but it was more effectually thinned by that dreadful pestilence called the *black death*, which desolated Europe from the year 1402 to 1404, and which extended its ravages even to Greenland. Those who escaped the plague probably soon fell victims to the Esquimaux; at least, nothing is known of them after the commencement of the fifteenth century. The terms eastern and western being used in reference to the original settlements, naturally led to the belief that the eastern as well as the western side of Greenland had been colonized; and a notion very generally prevailed for a long time that the western settlement only had perished, the eastern one having escaped the calamity, but, from the vast accumulation of ice, had been secluded from all communication with the rest of the world. During the last century the court of Denmark repeatedly despatched ships to ascertain if any settlers still remained on that part of the coast which is now called East or Old Greenland, but without success. A more recent boating expedition in 1829–30, under Captain W. A. Graah, of the Danish royal navy, has, however, in extent of research on the eastern side of Cape Farewell, yielded by far the most satisfactory information. He examined the coast as far north as 65° 45′ but found nothing to indicate that this coast had ever been colonized; and we are thus led to the conclusion that the notion of any of the Norwegians having settled on the eastern shores must be a mistake; a mistake arising from a misapprehension of the words *east* and *west*. In 1721 Hans Egede, a clergyman from Vaagen, in Norway, accompanied by his wife and family, left his native country to settle as a missionary in Greenland. He landed at Baals River in N. Lat. 64°, and called the place Godthaab, or Good Hope. Since that time the Danes have established numerous settlements upon the western coast of Greenland, lying between 60° and 73′ N. Lat. The whale fisheries have greatly contributed to the advancement of the colonies; and from the intimate intercourse which is now kept up with Europeans, their condition is at present more flourishing than at any former period.

There are, at present, thirteen Danish colonies in Greenland, besides some smaller establishments termed factories. For administrative purposes they are formed into two inspectorships, called respectively North and South Greenland. South Greenland lies south of N. lat. 67°, and comprises six colonies, as follows :—

	Founded.	Pop. 1845.	Of whom Danes.
1. Julianehaab, or Juliana's Hope........	1775	2336	41
2. Fredrickshaab, or Frederick's Hope	1742	650	10
3. Fiskenæset, or Fish Point..............	1754	485	20
4. Godthaab, or Good Hope...............	1721	801	25
5. Lukkertoppen..........................	1775	640	18
6. Holsteinborg..........................	1759	744	10
		5656	124

Julianehaab is the most southern as well as the most important of these. Its district extends to the most southern point of Greenland, Statenhuk, and beyond it for some distance along the east side. At Piskenæset the Danes carry on an extensive seal fishery by means of nets, &c. In its vicinity is the Moravian station of Lichtenfels, founded in 1758. Godthaab is the residence of the inspector of South Greenland; and in the vicinity is the Moravian settlement of New Herrnhut. Lukkertoppen takes its name from three pointed hills in the vicinity, resembling sugar loaves, and has one of the best and safest harbours in the country. North Greenland lies north of N. lat. 67°, and comprises seven colonies, as follows :—

	Founded.	Pop. 1845.	Of whom Danes.
1. Egedesminde, or Egede's Memory....	1759	767	15
2. Christianshaab, or Christian's Hope..	1734	420	14
3. Jacobshavn, or Jacob's Haven.........	1741	275	14
4. Rittenbenk..............................	1725	435	11
5. Godhavn, or Good Haven...............	—	249	17
6. Omenak..................................	1758	528	21
7. Upernivik...............................	—	405	18
		3079	110

Egedesminde, in Disco Bay, was founded by Captain Egede, and named in memory of his father Hans Egede. It comprises a number of large and small islands, but the proper settlement is on the island of Ausiet. Between this and Fox Island (Rævoe) there is a very secure harbour. A great many seals are caught here, especially in nets; but the collecting of eider-down forms the most important branch of industry. Godhavn, or Good Haven, in the southern extremity of the island of Disco, N. Lat. 69. 12., is the seat of the inspector of North Greenland, and has a coal-mine, which supplies the other settlements on Disco Bay with that article. Omenak is noted for its extensive seal fishery, which is carried on by the Greenlanders in their kaijaks or small boats and upon the ice, and by the Danes with nets which are let down the openings between the ice. There are here coal-mines which supply the colony. Upernivik is the most northern of these colonies, being in about N. Lat. 73., and though of recent formation, it is already one of the most important in North Greenland. The population of Greenland on 31st December 1845 thus amounted to 8735, being 8501 natives, and 234 Danes; and in 1851 is given at 9400, of whom 250 were Danes. This includes only those subject to the Danish crown; of those that may be scattered over the country, no conjecture can be formed.

We shall now give a brief outline of the discovery of the various sections of the coasts of Greenland, with occasional references to researches about proximate lands with which those on Greenland were more or less mixed up. This will lead us again to notice the enterprises of the sixteenth century in search of a passage by the north-west from the Atlantic into the Pacific Ocean.

During the reign of Queen Elizabeth, Frobisher, a distinguished English navigator, made several voyages to this quarter of the globe. In 1577 he discovered the straits which have been called after him. In the year 1585, Davis, another able seaman, came in sight of high land, which he called Mount Raleigh, supposed to lie somewhere on the west of the straits bearing the discoverer's name. In 1610 Hudson discovered the straits and the bay which are called after him, in which he experienced a disastrous termination to his useful career. To certain rocky islands lying about the 64th parallel, he gave the name of Isles of God's Mercy. He also discovered two capes, one of which was called Digge's Cape, and the other Willoughby Cape. In 1616, Baffin, one of the most distinguished of our English navigators, discovered the large expanse northward of the Strait of Davis, now known as Baffin's Bay. Sailing in a little vessel only of about fifty-five tons burthen, he effected one of the most extraordinary voyages on record. Under the imperfect appliances of the age for navigation, Baffin, with one small vessel, circumnavigated to Smith's Sound, on the north of that bay or sea which, northward of "Hope Sanderson, the furthest land Master Davis reached, lying between 72 and 73 degrees," was an utterly unknown region,—thus adding some 1100 miles of discoveries, reckoned by the mere coasting line, to the knowledge of these ice-encumbered shores. His exploration northward reached, it would appear from the brief but graphically told story of his voyage, as given among the *Pilgrimages* of Purchas, as high as about 77° 47′ of latitude, where he obtained a clear view into Sir Thomas Smith's Sound, which he describes as running "to the north of 78 degrees, and being the greatest and largest in all the bay."

---

[1] The following is a translation of the inscription by Dr Rafn, secretary of the Royal Antiquarian Society of Copenhagen:—"Erling Sigvatson, and Bjarne Thordarson, and Endride Oddson, erected these memorial stones, and cleared the place, on Saturday before Gagndag (the 25th of April), in the year 1135."

For 200 years from the time of Baffin the knowledge of this great inlet (excepting some limited and unpublished information obtained by occasional enterprises of the whalers) had not been advanced. In the year 1818, however, in consequence of information, we believe, communicated by Captain Scoresby to Sir Joseph Banks, the admiralty fitted out two expeditions; one of which, under the command of Captain Ross, was destined for the discovery of the north-west passage; and the other, at the head of which was Captain Buchan, had for its object to attempt a voyage across the pole. On the western side of Greenland, the first-named navigator discovered a high mountainous region to the north of Upernivik, to which, from national predilections, he gave the name of the Arctic Highlands. It is little else than a mass of rocks, intermingled with immense blocks of ice. He then proceeded towards the northern extremity of Baffin's Bay, which he explored as far as the ice would permit, looking from a distance into Smith's Sound. He surveyed the coast generally, ascertained the positions and the appearance of the land, the situation of the islands, and the general configuration of the great inlet, from the 78th down to the 65th parallel. The discoveries of Baffin, which some had disputed, were thus signally confirmed; for whilst the form of the bay, as given mainly from conjectural applications of Baffin's descriptions, was found to be thoroughly erroneous, the several deep inlets and other remarkable features of the coast-line, as noted by this admirable voyager, were not only easily recognised, but the latitudes and more striking particularities were found to be characteristically correct.

But the limited period of a mere summer's voyage having left several points in Ross's course defective and inconclusive, especially as to the supposed closing up of Lancaster Sound by continuous land, another expedition was sent out the year following under Captain Parry, who succeeded not only in passing through this famous inlet of Baffin, but in discovering a navigable channel among islands extending far westward, which was successfully pursued for about thirty degrees of longitude beyond Ross's furthest. But as these researches, with the general body of the discoveries since then made, fall beyond the limits of our present article, we must refer, for an abstract of them, to our general account of the Polar Regions. The chief additions to our knowledge of western Greenland which remain to be noticed consist of certain corrections of the coast-line incidentally made by the westerly exploring expeditions, and more accurate information of Smith's Sound and the coasts immediately beyond, resulting from Captain Inglefield's voyage in the summer of 1852, and from the very successful and interesting American exploration, still further north, under Dr Kane in 1853–5.

Captain Inglefield, in the Isabel, fitted out by Lady Franklin, having the advantage of an auxiliary steam power, made an advance northward of Baffin's furthest of about 50 miles, reaching within Smith's Sound to 78° 28′ N. latitude, and obtaining the view of a sea expanding again considerably beyond.

The exploration of this new expanse into the main Arctic Ocean (with which the Greenland sea in the east, and Behring Strait in the west, communicated), by the second American search expedition under Dr Kane, completes our sketch of the progress of discovery on the western side of Greenland. This hardy and intelligent adventurer, in a little solitary vessel, the brig *Advance*, pushed his way through Smith's Sound in the month of August 1853, and crawled along shore within a cram of dangerous ices which all but filled the passage, to a position higher in latitude (about 78° 40′) than had ever before been taken as a wintering station in these western regions by Europeans. In this position the brig was frozen in, early in September, and so remained throughout the succeeding summer, and with so little prospect of release as to occasion her abandonment, after a protracted adherence to her of above twenty months.

From this high position in latitude, explorations (furthered for a time by the effective aid of their Esquimaux dogs) were perseveringly made, and rewarded by results of the most interesting nature in geography, hydrography, and *glaciology*. The coast of Greenland, forming the *eastern* boundary of Smith's Sound, was traced northerly and easterly, until the exploration was diverted by a stupendous glacier of a vast extent, with a precipitous face about 500 feet in height abutting the sea. The geographical discoveries were pushed still further towards the pole, and new lands as high in latitude as 82° 30′ added to our charts. The lands on the two sides of this channel were found to be connected by apparently perpetual ices, having, at the time of the examination, an open sea beyond entirely free from visible encumbrance, whose waves were dashing with sublime action and force against the face of the icy barrier. Here an area of about 3000 square miles was seen entirely free from ice, the commencement and margin, as has been inferred, of an open *unfreezing* polar sea. On this question, however, which comes in more fitly for discussion in our article on the Polar Regions, we here only remark cautionarily against a premature conclusion, that Captain Scoresby, in his account of the arctic regions, describes an open sea, which he himself once observed and navigated, to the northward of Spitzbergen, running about E.N.E. and W.S.W. for 300 miles within the latitudes of 80° and 81° 30′, and having an area of from 15,000 to 20,000 square miles, or from five to six times the extent of that traced by Dr Kane; yet this apparently open polar ocean was found to be but a mid-glacial sea! Besides, the extreme lowness of the temperature in Dr Kane's case—being the lowest, on the mean, ever observed on the face of the globe—afforded sufficient evidence that there could be no such sea remaining open to the pole, beyond an incidental lake.

It does not come within the scope of our present article to dwell on the particular facts, and incidents, and processes of this admirable research by Dr Kane, except to notice the falling in with Esquimaux living in a region further north than any they had before met with. Agreeing as these natives in their general characteristics do with other Greenlanders, they were found to have incidental peculiarities in their habits and modes of living. They employ dog-sledges of great efficiency in speed, but have no boats or kaijaks. They surround themselves in *winter* with walls of moss, and, at that season, live mainly upon raw walrus flesh—habits of life which, for the season, Dr Kane and his party found it expedient, and, after a little experience, not unpleasant, to imitate and adopt. Under this new dietary education, raw walrus flesh soon became palatable; and even tallow candles, when they could be *spared* for such a purpose, were pronounced by the chief of the expedition to be very good! Useful and friendly as these natives were in their intercourse with Dr Kane and his party, they unfortunately possessed the infirmity (shall we call it?) too characteristic of the Esquimaux, of an insatiable habit of self-appropriation—stealing unscrupulously whatever they could manage to secrete, equally regardless of the damage to the owners, or of any possible use of the articles to themselves.

We may just add that Dr Kane, in the *Advance*, started on his expedition from New York on the 31st of May 1853, having along with him, in crew and associates, seventeen men. Three of this number, the cook, carpenter, and a seaman, died in the arctic regions, and the remainder returned safe to port on the 11th October 1855. The party left their vessel still fast in the ice on the 20th of May, and travelled over the ice to the navigable waters of Baffin's Sea, whence by means of their boats they proceeded to the settlement of Upernivik. They there took passage in a Danish trader; and when, in their progress southward, they reached Lievely in Disco Island, they met with the expedition of Lieutenant H. J. Hartstein, which had been sent out by Congress in search of them.

As to the *eastern side* of Greenland, all our *accurate* knowledge, except a few particulars referring to the coast near Cape Farewell, is of recent attainment. A coast-line, indeed, of the more southern parallels was to be found in our charts of the Arctic Regions, and in maps by Egede and Crantz, traced to a considerable extent, with an elaborateness of flexure that would indicate real and careful examination; but subsequent researches have by no means verified the supposed configurations.

Northward of the 70th parallel of latitude, all the geographical information we had of that coast previous to the voyage of Captain Scoresby (now the Rev. Dr Scoresby) in 1822, consisted of the not very definite notification of certain points of land discovered by the adventurous Hudson in 1607, with a few touches on the coast, and notices of land being seen by whalers, chiefly Dutch, in 1654, 1665, and 1670. In 1822, however, Captain Scoresby, whilst engaged in the Greenland whale fishery, and successfully pursuing the commercial object of his voyage, penetrated the ice westward, as he had previously provided for attempting, to the coast of Eastern Greenland. But the position of the coast, and its line of direction, were found to be widely different from those ascribed to them in the charts, whether English or Dutch; for the real place of the land in latitude 74° was found to be from 8° to 15° of longitude further west, and the line of direction from 69° to 74° 30′ N. by E., instead of N.E. or E.N.E. as formerly laid down.

The first land seen by Captain Scoresby, stretching from N.W. by N. to N., extended to about 74° 30′ N., the nearest headland being estimated at 50 miles distance. This was on the 7th of June, and so early in the season as to prevent any near approach to the coast, from the intervention of a chain of heavy field ice northward of 73°. But after tracing a proximate outline of the more northern part of the coast, Captain Scoresby was gradually enabled to approach the shore as, with the advance of the season, he proceeded southward; and in the course of the exploration, succeeded in landing on four or five different positions between the 70th and 73d parallels. The coast from 74° 30′ to 69° 10′ was generally surveyed, and names were given to the more particular headlands, islands, and inlets. Two very remarkable inlets were observed and partially examined, one in latitude 72° which was named *Davy's Sound*, and the other in 70° 15′, which received the name of *Scoresby's Sound*, on account of the first examination of it ever known to have been made having just been accomplished by the investigator's father. In this way, single-handed, and without cost to the country, some 600 miles of new coast line (reckoning its various flexures and inlets) were added to our Greenland charts; and much novel information on the geography, hydrography, and natural history of those regions was communicated to the public in the Journal of the Voyage, which appeared in the succeeding spring. One circumstance of geographical interest it may be proper more particularly to notice, viz., the conviction conveyed to the mind of Captain Scoresby by his observations on the current setting into Davy's Sound and Scoresby's Sound, that these fine expanses of water, which, in certain westerly directions, were clear of ice or land to the utmost extent of vision, were actual channels of communication between the sea of Greenland on the east, and that of Baffin on the west. Hence the great probability of the supposition already noticed, that Greenland consists of an *assemblage* of islands.

In the year 1823, Captain Clavering, in command of the Griper sloop-of-war, under admiralty orders for pendulum experiments, advanced on the same coast as that first approached by Captain Scoresby; and, being about a month later in the season, was enabled to get close in shore, and to enter a considerable bay in lat. 74°, supposed to be that originally discovered by Gael Hamkes, a Dutch navigator, in 1654. The line of the more northerly part of the coast, as laid down by Scoresby, was now corrected, and new coast-line, including Shannon Island, with dottings of headlands reaching from 74° 30′ to 76°, added to our charts. Southward of Gael Hamke's Bay the coast was traced pretty close along to Cape Parry of Scoresby, and then finally left. The general configuration of the coast, excepting some ten or fifteen leagues in the furthest north, seen by Captain Scoresby only in the distant horizon, was singularly verified by Captain Clavering's inshore researches. For though the first explorer was not able to approach the land between 73° 30′ and 74° 30′ N., nearer than from 40 to 45 geographical miles, the positions ascribed by the two navigators to the headlands of Gael Hamke's Bay, and other leading points (with Jackson's Island, which had been first laid down at about 30 miles distance), proved to be all but identical.

This coast presents many remarkable and interesting features. On the Liverpool coast of Scoresby there is a mountainous chain of 3000 to 4000 feet in height, forming precipitous cliffs, which terminate in numerous peaks, cones, pyramids, or series of perpendicular serrated points. In the interior were seen peaks supposed to be almost twice the elevation of the lofty coast. The coal formation of Jameson's Island, in Scoresby's Sound, was among the most interesting of the geographical particulars observed.

The final researches, which terminate our description of the eastern coast of Greenland, were those made by Captain Graah in the years 1829 and 1830, by order of the king of Denmark. The leading object was to search for the lost colonies, and trace the coast, if practicable, in boats, from Cape Farewell up to latitude 69° N., the southernmost point discovered by Captain Scoresby. The expedition consisted of two *women's boats* of the country, rowed by women, carrying the Danes of the party (Captain Graah and three others), and attended by five men in their kaijaks. From the southern island, Cape Farewell, up to latitude 65°, the coast was found to trend about N.N.E.; and from thence, for 60 to 80 miles (as far as they were able to trace it), the line was about N.E. The highest point on Captain Graah's chart extends to 65° 45′, leaving the interval of about 340 miles (in a north-easterly direction) yet uncertified and unknown. The pressing of the ice in close contact upon the land prevented the further navigation of these eastern shores.

The aspect of a country subjected during the greater part of the year to an intense degree of cold, and also for several months deprived of the light of the sun, must of course be dreary and desolate in the extreme. A fall of snow in the midst of what is here called summer, only because it is not so dismal as the other parts of the year, is by no means uncommon. Towards the end of autumn it begins to descend in a regular succession of showers, which continue until every object is buried beneath a sheet of dazzling whiteness. Ice also begins to form about this time, first upon small streams and lakes, then upon larger ones and inlets of the sea, and finally upon the ocean itself, a vast extent of the surface of which becomes a solid frozen mass.

Ere the frost has reached its highest degree of intensity, the air deposits its moisture in the form of a fog, which freezes into a fine gossamer netting or into spicular icicles. The surface of the ocean also assumes a very remarkable aspect. It steams like a lime kiln, a phenomenon called *frost rime*, and caused, as in other instances of the production of vapour, by the water being still warmer than the superincumbent atmosphere. As the cold increases both these appearances vanish; the air clears; and the sea, cooled down to the same standard, becomes a solid floor of congealed salt water. Winter now broods over the frozen regions of the higher latitudes in darkness unbroken save by the light of the moon and the stars, which serves to reveal the desolation of the scene. Halos and luminous meteors are also more numerous here than in lower latitudes. But the aurora borealis, in particular, is highly serviceable in breaking the monotonous gloom of an arctic winter. This brilliant meteor plays almost incessantly in fantastic coruscations, which have the appearance of very vivid sheet lightning, and keep up an almost constant illumination. Captain Parry observes, "The sound of voices, which, during the cold weather, could be heard at a much greater distance than usual, served now and then to break the silence which reigned around us; a silence far different from that peaceable composure which characterizes the landscape of a cultivated country; it was the death-like stillness of the most dreary desolation, and the total absence of animated existence." During this cheerless period of the year, the natives, thickly covered with skins, remain generally immured in their miserable huts; and, crowding around the stove or lamp, contrive, as far as possible, to doze away the long and tedious night. The inside of the hut, all openings in the walls of which are carefully stopped to exclude the piercing cold, becomes covered with a crust of ice; and if for an instant an aperture be made so as to admit the external air, the moisture within becomes precipitated in a shower of snow. It may be remarked, however, that the external darkness prevails only during a part of the day. Twilight exists whenever the sun is less depressed than eighteen degrees below the horizon: the limits of total obscuration occur in the latitude of $84\frac{1}{2}°$, at mid-day in the winter solstice. Captain Parry's party, when in latitude 74° 40′, could see to read the smallest print at noon in the middle of winter. After the sun has appeared above the horizon, the half-famished inhabitants venture forth in search of food about the shores of the sea. In June and July the sun is always above the horizon. The heat, thus greatly augmented, gradually dissolves the perennial ice. The icy covering of the ocean breaks, and, separated into vast masses, is driven about, dissevered, and dispersed by the winds and currents. In particular situations the snow and ice of successive years are cast into immense glaciers, the foundations of which being sapped by the sea, break off in prodigious masses, and, floating far into the ocean, present to the mariner a bright but fearful spectacle, reflecting in varied tints the rays of light, yet threatening, if come in contact with, to crush to pieces the stoutest vessel. Not unfrequently they are borne to a great distance into lower latitudes. In these high latitudes, although the summer is short, the temperature is frequently oppressively sultry on land, which causes great humidity in the atmosphere; a characteristic of the arctic regions.

The mineral productions of the arctic regions are of considerable interest. Only the shores of the country, however, have been examined, the interior remaining unexplored, on account of the eternal ice and snow under which it is buried. The rocks, as far as they have been examined, are principally of the primitive formation, consisting of granite, gneiss, mica slate, hornblende slate, syenite, and clay slate. Among the secondary rocks is found the secondary sandstone, or coal formation; similar to that which abounds in the vicinity of Edinburgh, and containing impressions of plants. Specimens of the coal formation, collected by Captain Scoresby, were found by Professor Jameson to contain impressions of tropical plants; a very interesting fact, as connected with the change of temperature which the earth appears to have undergone. The most northern part of the coast of East Greenland examined by Captain Clavering was mountainous, and principally composed of trap rocks; lower down Captain Scoresby found the primitive rocks the prevailing ones among a large and very general range of geological series. The west coast of Greenland is similar to that above described. The elevated parts of the country are for the most part covered with snow or ice; and in summer, although rivers appear, which are fed by the melting of the ice and snow, they are few and inconsiderable in size. There are also lakes, some of which are of considerable magnitude, and supplied from the same source as the rivers. Springs likewise burst forth; and Giesecke mentions a tidal spring (rising and falling with the tide), and a thermal spring, which maintains a temperature of 104°, and flows uninterruptedly during the whole of the year. The islands upon this coast, the largest of which is called Disco, are similar in formation to the continent, and present the same bleak and wintry sterility. Four formations have been found on the coast of West Greenland; namely, primitive, secondary, tertiary, and alluvial. In the first of these, various curious and rare minerals occur, such as the cryolite, gadolinite, zircon and sodalite, tourmaline, and numerous precious stones, such as garnets, iolite, rock-crystal, and the like; and in the secondary and tertiary rocks, limestone containing fishes, and imbedded amber, have been found. Copper-ore is said to be abundant in various parts; and plumbago, iron-ore, and tin-stone, are found. The lands bordering on Baffin's Bay, and the islands lying at the northern extremity of it, are not much elevated above the level of the sea, the average height being 800 feet, and the highest elevations seldom exceeding 1500 feet.

The vegetation of a soil which for two-thirds of the year is bound together by intense frost, and covered with snow several feet thick, cannot be supposed to present much variety or beauty. Even the hardy race of pine trees, which in North America during severe cold withstand the fury of the northern tempest, if they make their appearance at all within the Arctic Circle, dwindle into stunted shrubs, which only rise a few feet above the ground, throwing out lateral branches. But to supply this deficiency, and afford to the Esquimaux the means of making their arms and utensils, considerable quantities of drift timber are frequently thrown up on the barren shores. The most abundant plants are mosses and lichens; and these are not only copiously produced, but they possess a nutritious and salutary quality, which does not characterize those of the same species that grow in more temperate climates. Mushrooms and ferns also find the means of subsistence here; and there is a thick tufted juicy plant, of extreme fecundity, emphatically called scurvy-grass, on account of its acting as an antidote to scurvy. The different species of sorrel, especially the *Rumex digynus*, are found flourishing under the snow at the very furthest limits of vegetation. These are likewise antidotes to scurvy. During the short gleam of summer some beautiful specimens of the floral tribe adorn the vegetative patches, but little of vegetable production useful as food can be raised under this ungenial sky. The order *algæ*, especially the species or tribe *fucus* or sea-weed, grows in great abundance, and covers the Greenland coast with submarine meadows. The singular phenomenon of *red snow*, which has excited so much interest, is now supposed to result from an assemblage of very minute vegetable bodies belonging to the class of cryptogamic plants, and is termed *Uredo nivalis.* The arctic mountains on which Captain Ross observed the red snow are about 800 feet high, and extend eight miles in length. Captain Scoresby observed the same phenomenon on Rathbone Island on the eastern coast in 1823. Although snow is not the natural situation of this plant, it possesses a great tenacity of life, and not only preserves its vitality in winter, but, during the partial thawing of the snow it multiplies so as to cover a vast expanse with red suffusion.

Although vegetation be scanty and unimportant in the arctic regions, there is a remarkable profusion of animal life. The sea, in particular, swarms with living beings, some of which are of a magnitude far surpassing anything to be met with elsewhere. One of the grand articles of food for supporting these numerous tribes is the genus *Medusa* of Linnæus, graphically called by seamen sea-blubber. These animals are of a soft, gelatinous consistence, and they abound to an extraordinary extent. By far the most numerous of the medusan tribes, however, are very minute; but so plentiful are they, that about a fourth part of the Greenland sea is tinged of an olive-green colour by them. This portion of the ocean is considered as the polar pasture ground, where whales used to be met with in greatest numbers. Animals of the class *Crustacea* stand next in number and importance as food for the whale. Here various species of the crab occur in large numbers, as well as of the shrimp, whose carnivorous propensities, as observed by Parry, are remarkably strong. Many of the zoophitical and molluscous orders, and several species of marine worms, also abound. But the cetaceous tribes are by far the largest in size, and most important to mankind, of the numerous living beings which inhabit the northern seas. The largest of these is the whale, the *mysticetus* being sometimes sixty feet in length, and the *rorqual* nearly a hundred. Of whales there is a considerable variety; and the catching of them has long been a lucrative speculation, on account of the oil and whalebone derived from them. All the shores and borders of the arctic zone are frequented by huge amphibious races, which seem to form an intermediate link between whales and quadrupeds, between the mammalia of the ocean and those of the land. Amongst these is the morse or walrus, a large and unwieldy creature, measuring from twelve to fifteen feet in length, and from eight to ten in circumference. Seals are very numerous, and constitute both the food and the clothing of the Esquimaux, and a profitable fishery to Europeans. Amongst land animals is the polar bear, whose ferocity and daring render him one of the most formidable of quadrupeds. The rein-deer are pretty numerous in some parts of Greenland during summer, and afford a favourite object of chase. Their flesh is good, and the skin forms a very comfortable article of clothing. The arctic fox is met with in considerable numbers. The dog, however, is the most important quadruped, and the most valuable to the Esquimaux, who have succeeded in taming and rendering it subservient to them in travelling and in hunting. Yoked to a sledge, these animals can draw a great weight with very considerable rapidity. Land birds are not numerous, but the number of sea-fowl is incredible. The auk, the petrel, and the gull, in clustered myriads darken the sky, and make the rocks and shores re-echo with their wild clang. The goose and the duck are also met with in these regions; and great flocks of that species of duck called the eider, whose down is so valuable, arrive in spring on the most northern shores of Greenland. Amongst other arctic birds are terns, which produce the most delicate eggs of any water bird; the *colymbus* (guillemot), whose skin affords a comfortable article of clothing; the *tringa* (sand-piper); the *charadrius* (plover); and the *tetrao* (grouse and ptarmigan).

The native inhabitants of these countries are the Esquimaux, a race widely diffused over the shores of the Northern Ocean.

Like the vegetation of these high latitudes, the human figure is dwarfish in size, and decidedly below the European standard. A man five feet nine inches in height is considered as a person of gigantic stature, and, compared with the average altitude to which they attain, as possessing amongst them the same superiority of size which a person six feet two or three inches in height does amongst us. The body is somewhat thick, but the hands and feet are small, and the fingers short. The face is generally round and flat, with prominent cheek bones, but full and plump cheeks. They are tolerably well shaped; and the female countenance, although destitute of all pretensions to regular beauty, has a frank and good-humoured expression; and if they would allow it to be purified of its thick incrustation of grease and dirt, it might even be accounted handsome. The flesh of these people is soft and flabby, and they have a phlegmatic constitution corresponding to this habit. The dress of the men consists chiefly in a double coat of seal-skin or rein-deer; the hairy side of the inner one being placed next the skin, whilst to the outer one there is an ample hood attached, which is drawn over the head. Their breeches are also double, and of the same material, overlapping the boots, which extend to the knee; the latter are composed either of deer skin, or, if for hunting or travelling, of the hide of the seal or the walrus. The dress of the females is very nearly the same, with some slight variations in form. The chief distinction lies in their boots, which are of capacious dimensions, and, like those of Hudibras, receptacles for whatever sort of goods may come in the way of the wearer. These habiliments are very neatly sewed together, an art in which the women display considerable dexterity. The thread they use is the sinews and some other parts of animals. There is also some taste shown in decorating them with parti-coloured stripes of skins. Like other savages, they are fond of ornaments, and contrive also to paint their bodies.

Under such a rigorous climate, much labour is necessary to secure subsistence. For nine months the ground is locked up in frost, and rendered incapable of producing any root or herb which can constitute a staple article of diet. They are, moreover, improvident; in consequence of which, combined with the precarious supply of food, they are often subjected to severe privation. Yet they are proof against the lessons of experience, and so happy is their disposition, that a moment's gratification of their wants makes them forget that they had ever suffered from hunger, or that on the morrow they may again be in the same distress. Hunting and fishing are their only resources, and of course their time is spent in pursuing, by land or sea, the wild animals by which these are inhabited. During summer, the deer is pursued with bow and arrow or the gun, and their flesh and skin are highly prized. But for the greater part of the year the Esquimaux must seek their food in the waters, from the seal, the walrus, and sometimes the whale. For the purposes of respiration, these animals rise above the water, and the moment they become visible, the Esquimaux attack them with dart or harpoon, to which they have sometimes a long line attached. The capture of a whale is the greatest and rarest of their marine achievements. On these occasions a large body of men assemble armed with a variety of weapons. The animal, when struck, plunges under water; but being obliged to rise for air, a fresh attack is made upon him with their lances, until, exhausted by fatigue and loss of blood, he falls their prey.

These captures are shared amongst the inhabitants of the village, all the cooking pots in which are put in requisition when the arrival of one is announced, for the purpose of boiling the flesh of the animal, which is cut up into dainty slices. The cooking being finished, the feast commences by a person first extracting a large piece from the pot, and, after severing with his teeth as much as the mouth will hold, handing it to a second person, who does the same. and he to a third, and so on till the whole is devoured. There seems to be no assignable limit to the capacity of an Esquimaux stomach. He has been known to devour, in twenty-four hours, ten pounds four ounces of solid food, more than a pint of strong soup, and a gallon and a pint of water.

A single Esquimaux, assisted only by his dogs, will attack the polar bear without the slightest fear or hesitation; which indicates no small amount of personal courage. The dogs keep the ferocious animal at bay, assailing him on all sides, whilst the master attacks him with his spear, and avoids, with astonishing adroitness, the furious springs of the enraged monster. In reflective intellect the Esquimaux have little to boast of. Although some of them are arch, ingenious, and jocular, no manifestations of a profound understanding have yet been discovered amongst them. In arithmetical skill they are lamentably deficient, being scarcely capable of counting as far as ten; and their taste for music is nearly at as low an ebb. Some of them, however, display a constructive talent, in exercising which the principal tool employed is the knife. Their houses are built of various forms and materials, according to the season and the region of their residence. Some of their winter houses are of stone and earth, partly sunk in the ground. Others are of snow and ice. Those of ice are built in the following manner: When winter approaches, the ice is cut into tall square blocks, with which they construct regular spacious domes, connected with other smaller ones, for the purposes of domestic economy. For the admission of light, a round hole is cut on one side of the roof of each apartment, and a circular plate of ice, three or four inches thick, and two or three feet in diameter, is inserted in it. The light is soft and agreeable, similar to that which is transmitted by ground glass, and is quite sufficient for every purpose as long as there is any light to be derived from without. The inside of the tenement is shaped with care, and a glossy surface is then given to it by the effusion of water. The wall soon becomes a solid mass, which, being a slow conductor, checks the access of cold. As soon as the snow melts, the Greenlanders quit their wintry habitations, and erect their tents, which are of two kinds; one of these is of a pretty solid construction, and such as forms a fixed summer residence; the other is of a lighter nature, and can easily be removed from place to place. It generally consists of poles, upon which the skins of animals are stretched. Their boats consist of a light frame-work of wood or bone, which is covered with seal-skins. There are two kinds of them; one large for the transport of goods and for the conveyance of women; the other small, and fitted to hold only one man. The top of the latter, which is called a kaijak, is covered over with seal-skin, but in the middle there is a round opening for the reception of the Greenlander, who, here seated, propels himself through the deep by means of an oar, which is furnished with a broad blade at each end. With this slender vessel he swims over the billows like a sea bird, and without much dread of tempests.

In their moral character the Esquimaux inherit more than an average share of human frailty. Few savage tribes have made themselves more notorious for dishonest and thievish dispositions. They will steal the most useless things. Little respect indeed is entertained for the rights of property; gratitude is a virtue almost unknown amongst them; and in their habits they are exceedingly licentious, connubial infidelity being winked at as a very unimportant matter. But some tribes, especially those seen by Captain Graah, appeared to possess a much higher moral character. They also display little or no sympathy or regret for the sufferings and death of neighbours, or even of relations. The Esquimaux, however, are not inclined to war; they are neither irascible nor revengeful; and they treat their offspring with the greatest tenderness. In their domestic economy, however, they are uniformly filthy, and disgusting in the extreme.

These descriptions, however, only apply in their full extent to original Esquimaux who have had little or no intercourse with Europeans. In the various missionary stations the grosser aspect has been much modified and changed by the influence of Christian teaching. And among a no inconsiderable number of the people the true principles of the gospel have taken root, and the effects of it have become apparent in their lives, so as to yield an improvement generally among the population around, and very many individual examples of the true Christian character.

Their language is remarkable for the copiousness of its grammatical forms. Their particles are as numerous and as varied as in the Greek; but the rule which directs them to introduce into the verb all the parts of the sentence gives rise to words of a disproportionate length. The consonants *r*, *k*, and *t* predominate in this language, and produce harsh sounds by their frequent recurrence. The Greenlanders of the north speak a dialect unintelligible to those of the south; according to Captain Ross it is called *Kumooke*. The Greenlanders sometimes call themselves *Innouk*, or brothers; but their real national name appears to be *Kalalit*, and they commonly designate their country by the name of *Kalalit Nounet*. The trade of Greenland is a monopoly in the hands of the Danish government. Five or six vessels are annually sent from Copenhagen, about the beginning of May, with manufactures of various kinds, as well as colonial produce, as coffee, sugar, tobacco, &c. The exports from Greenland in 1847-9 averaged about L.17,000 annually, and consisted chiefly of seal-skin, deer-skin, oil, whalebone, and eider-down. (W. S—Y.)

GREENOCK, a seaport town of Renfrewshire, Scotland, on the south bank of the Firth of Clyde, 22 miles below Glasgow, in N. Lat. 55. 57. 2., W. Long. 4. 45. 30. In front of the town there is a fine and extensive bay, formerly known by the name of the Bay of St Lawrence, from a religious house that anciently stood there. Behind the town the land rises into a picturesque ridge of hills, about 800 feet high, between which and the bay Greenock stretches for upwards of two miles and a half along the shore, but its breadth is inconsiderable. Its name is supposed to be derived from the compound Gaelic word *Grianaig*,—*Grian* signifying sun, and *Aig* port or bay,—the bay being directly opposite to the rising sun.

In the earlier part of the 17th century Greenock was an obscure fishing village, consisting of one row of thatched cottages; and in 1716 there were only six slated houses in the place. In 1589 James VI. granted leave to Schaw, the proprietor, to erect a place of worship for the convenience of the inhabitants of the district.

In a charter, dated 5th June 1635, granted by Charles I. as administrator-in-law to his son Charles, Prince of Scotland, in favour of "Johne Schaw of Greinock, and Helen Houston, his spouse," a novodamus grant is made

"To the saids Johne Schaw, his spouse, and thair foresaids, off the toune or village of Greinock, in ane frie brugh of barronie, to be callit, now and in all tyme cuming, the brugh of Greinock." This charter, which was ratified by the Scottish parliament in 1641, appears to have excited the jealousy of the neighbouring *royal* burgh of Renfrew, whose representative, John Spreule, "protested, in name of the Provost, Bailzies, Counsel, and Communitie of the brugh of Renfrew," that any ratification of the charter "be nae ways prejudiciall to our said brugh liberties, and priviledges thereof, contenit in our antient infeftments as accords of law."

Being merely a burgh of barony, and thereby excluded from the right of foreign trade, Greenock had to contend with the royal burghs in its immediate neighbourhood, Dumbarton, Renfrew, and Glasgow, to which alone this privilege was accorded. A second charter by Charles II., and dated 11th July 1670, grants in favour of "John Schaw of Greenock in liferent, and of Sir John Schaw, now of Greenock, designed therein his eldest lawful son in fee" of the lands and barony of Greenock, "with the *harbour* built and erected thereupon;" a new grant is made "to the said Sir John Schaw, younger, of Greenock, and his airs male," of all casualties of superiority which might have accrued to His Majesty, "by reason of ward, nonentrie, forfaulture, *purpresture* . . . . or for building and edifieing the foresaid *Harbourie.*"

It is evident from these extracts that in the interval between 1635 and 1670, John Schaw, the elder, had built a harbour at Greenock; and as he had thereby incurred the penalty of purpresture by encroaching on the ground between the ebb and flow of the Clyde, the last charter was necessary to exonerate him therefrom. It further conveyed "special and full power and libertie to the said umgl. John Schaw, and his said sone, and their foresaids, to repair and build *free Ports, Harbouries,* and *Havening-places,* upon any part of the grounds of the said lands." John Schaw, the younger, had distinguished himself in the royal cause at the battle of Worcester, for which the honour of knighthood had been conferred upon him, as was subsequently that of baronetcy; and to this may probably be attributed the favourable provisions of the charter.

For upwards of a quarter of a century the original harbour appears to have remained little more than an insufficient and insecure landing-place; but on 22d September 1696, an overture was made in the Scottish parliament "for building ane harbour at Greenock;—read, and remitted to the committee of trade." To this overture reference is made as follows, in the minute of parliament of 29th November 1700:—"Petition; Sir John and John Schaw's, elder and younger, of Greenock, craving that the act brought in from the committee of trade, allowing the imposition therein-contained for building ane harbour at Greenock, be now passed; and the draft of the said act being also read, *it was ordered to lye on the table.*" The petition and draft were again read on 23d December, but nothing further was done.

Sir John Schaw died in 1702, and was succeeded by his son of the same name, who, with equal zeal, prosecuted the erection of a harbour. Notwithstanding the refusal of the legislature to aid the undertaking, he resolved to accomplish it by advancing his own money, and encouraging his feuars to advance theirs. To secure repayment an assessment was voluntarily imposed, and a regular contract to this end entered into in 1703. The harbour thus originated underwent, in the progress of its construction, many alterations and additions, of which no record now remains; it was not finished till 1734. It then comprised an area of 8 acres, 3 roods, and 10 falls; was contained within two quays, east and west, and equally divided in the centre by a middle quay.

The prosperity of Greenock had continued to advance from the period of the Union in 1707; and in 1710 it was established a custom-house port, and a branch of Port-Glasgow. In 1751 application was made to parliament, and an act (25 Geo. II.) was procured whereby an imposition of two pennies Scots, over and above the duty of excise payable to his Majesty, was laid upon every Scots pint of ale or beer that should "either be brewed, brought in, tapped, or sold within the said town of Greenock"—made payable to certain trustees—"for cleaning, deepening, building, and repairing the said harbour and piers." This tax continued to be levied for thirty years.

Prior to 1772 the harbour had been leased to the town by the superior; in that year, however, the magistrates received a feu-right thereof from John Shaw Stewart, Esq., who had succeeded to the Greenock estate on the death of Sir John Schaw on 5th April 1752. On the completion of this transaction, the magistrates having resolved on the erection of a new quay, a plan of the ground requisite for a new harbour was prepared under the engineering superintendence of James Watt; and a feu-right thereof was granted to the magistrates by Lord Cathcart, who was the grandson of Marion, the only child of the last Sir John Schaw, and inherited thereby a part of the Greenock estate. The transaction is dated 3d March 1773; and at the same time the magistrates and council brought their first bill into parliament, "for deepening, cleansing, and making more commodious the harbour of Greenock." This act received the royal assent on the 1st of April following; and the works it contemplated were prosecuted during many subsequent years.

Various acts of parliament having reference to successive enlargements and alterations of the harbours were from time to time procured as the increase of trade rendered such necessary, so that now of the original erections scarcely a vestige remains. In 1785 a dry dock was built in the western division of the old harbour, the expense of which was defrayed by subscription; and in 1818 the magistrates and council contracted for and built another, and greatly larger, entering from what is now known as the East India Harbour, and which was finished in 1824 at an expense of L.20,000.

On the 29th day of May 1805 was laid the foundation-stone of the East India Harbour; and almost contemporaneously with this large addition to the dock accommodation of Greenock, a general improvement and renovation of the quays and breasts of the older portions of the harbour were undertaken. These works, which were very extensive, and involved an expenditure of upwards of L.120,000, were not completed till September 1819.

The steadily increasing trade of the port rendered a further extension of dock accommodation absolutely necessary; and in 1840 an act was procured for the construction of an entirely new harbour and dock. Six years subsequently, the work was commenced on a site directly east of the East India Harbour, and on the 17th October 1850 the new dock was formally opened, under the designation of Victoria Harbour.

It consists of a tidal basin, covering an area of about 6 acres, and exceeding 30 feet in depth. The east and west walls are each 563 feet long; and the outer quay wall, divided by the entrance, 150 feet wide, is 176 feet long on the west, and 60 on the east side. The average width of the quays on the east, west, and south, is upwards of 85 feet, and on the north, toward the river, it is 70. The depth of water within the basin is 26 feet at high tide, and 14 feet at low water. The whole work, which is of the most substantial character, cost upwards of L.120,000; and, as a tidal harbour, has not, in respect of its size and depth, its equal in the world. On the east side a massive crane, capable of lifting from 70 to 80 tons, has been erected; and here many of those gigantic steam vessels, for which the Clyde has become universally famous, are fitted with their engines. A crane has also been erected at the East India Harbour capable of lifting 40 tons.

With the clay and earth dug out of the Victoria Harbour an embankment was formed toward the west end of the town, reclaiming upwards of 4 acres of ground between high and low water-mark. The walls, which are founded 6 feet beneath low water, extend 600 lineal feet parallel with the river, and upwards of 300 feet on the east and west. A landing slip is formed on the eastern side. The depth of water hereby secured is at high tide from 16 to 18 feet. This embankment is denominated Albert Quay, and is used for the discharge of timber-laden vessels: a portion has recently been leased for a ship-building yard.

The old graving docks having become altogether inadequate, the harbour trustees have recently purchased, for upwards of L.30,000 several acres of ground adjoining Albert Quay, and here it is in contemplation to construct a new harbour, with the requisite dock accommodation for repairing the largest vessels.

The following measurements show the extent of the existing dock and quay accommodation:—

Albert quay and slip.....	906 lineal feet.
West harbour and quays	3940 feet, girthed.

Entrance to harbour	130	feet wide.
Custom-house quay	990	... ...
East India harbour and quays	3200	... girthed.
Entrance to harbour	170	... wide.
Victoria harbour and quays	2200	... girthed.
Entrance to harbour	150	... wide.

The harbour trustees, who manage the affairs of the docks, consist of the town-council, and commissioners annually elected. Greenock enjoys coasting and foreign trade to a very considerable extent. In 1719 a vessel from this port first crossed the Atlantic; but shortly afterwards the shipping rapidly increased, for the Union had now opened full prospects to Scottish industry. With such rapidity did Greenock extend her maritime relations that the jealousy of the traders of London, Liverpool, and Bristol was excited. They accused the merchants of Greenock and Port-Glasgow of defrauding the revenue, but the charge was triumphantly refuted. The earliest trade seems to have been in herrings, and it is still continued, the amount cured annually averaging about 19,000 barrels. Trading in tobacco was also carried on at a very early period. It was first brought from the colonies, and then exported to the Continent. The Greenland whale-fishing commenced as far back as 1752, but it never rose to be of any importance, and is now discontinued. The American War greatly interrupted the progress of Greenock, as the principal trade of the port was then with that country; but after the peace in 1783 it speedily revived, and within the seven following years the shipping trade was tripled in amount. At present the principal intercourse is with the East and West Indies, Australia, and North America. Newfoundland and South America have also employed a considerable quantity of shipping. The gradual increase of trade is shown by the following tables:—

Account of the gross receipt of customs at the port of Greenock during 1728, *and various subsequent years.*

1728	L.15,231	1839	L.315,084
1770	57,336	1846	324,477
1802	211,087	1848	407,083
1822	263,464	1851	410,206
1831	592,008	1852	429,535

The stationary state of the duties of late years is ascribed partly to their reduction, and partly to the improvements effected in the navigation of the Clyde, which enable vessels that formerly had to load and unload here or at Port-Glasgow, to ascend to Glasgow.

Account of the number of registered vessels belonging to the Port of Greenock during the years 1825, 1834, 1845, *and* 1853.

	No.	Tons.
1825	241	29,054
1834	367	40,733
1845	428	82,744
1853	418	73,898

Of these last, 14 vessels, with an aggregate of 2012 tons, were steamers.

Account of the number and tonnage of vessels that entered and cleared from and to foreign ports in various years since 1784.

	INWARDS.				OUTWARDS.			
	British.		Foreign.		British.		Foreign.	
	No.	Tons.	No.	Tons.	No.	Tons.	No.	Tons.
1784...	52	6,569	4	530	63	7,297	3	520
1804 ..	165	30,802	25	5,120	155	31,896	20	5,965
1824...	188	46,162	11	3,054	188	46,857	9	2,699
1834...	277	69,843	10	2,073	284	71,698	8	2,140
1853...	274	94,575	44	13,764	153	55,630	45	11,975

In 1830, 684 vessels of 67,884 tons entered, and 796 vessels of 81,988 tons cleared coastwise at the port.

In 1853, 574 sailing vessels of 38,328 tons, and 214 steam vessels of 39,511 tons entered, and 162 sailing vessels of 8662 tons, and 102 steam vessels of 10,752 tons cleared at the port.

Prior to 1741 the police and burgh affairs of Greenock were exclusively in the hands of the superior, through whose baron-bailie they were ministerially discharged. By a series of charters, however, dated respectively 30th January 1741, 10th April, and 2d September 1751, Sir John Schaw conferred power upon the feuars and sub-feuars to elect nine trustees from among themselves, whereof two to be bailies, one to be treasurer, and the other six to be councillors for the good government of the town, and public funds thereof. Authority was given to hold weekly courts, to punish delinquents, to make laws for maintaining order, and to admit merchants and tradesmen to the privilege of burgesses. The burghal affairs of the town continued to be administered under the charter of September 1751 till 14th November 1833, when the election of councillors took place under the provisions of the Reform Act. That act conferred no special benefit upon Greenock in respect of the election of councillors, as under the charter referred to, the qualified electors of Greenock formed the most numerous constituency in Scotland. The town is divided into 5 municipal wards; and the town-council consists of a provost, 4 bailies, a treasurer, and ten councillors. A sheriff criminal court, sheriff small-debt court, and justice-of-peace court respectively are held every week.

Greenock has a very irregular appearance, and, until lately, the drainage of the town was very defective. A thorough system of drainage, however, has recently been instituted, and a corresponding improvement in the healthiness of the place is the result. The town is rapidly extending on the east by the increase of ship-building yards and other public works; and on the west a series of elegant and handsome villas stretch along the shore. The view from the heights above the town is exceedingly beautiful. Amongst the public structures which deserve to be noticed is the custom-house, a handsome edifice in a good Doric style, erected in 1818, at a cost of L.30,000. It is seen to much advantage, being situated in the centre of the quay. The tontine is a substantial and handsome building, erected in 1801, at a cost of L.10,000, and containing one large hall, and many smaller rooms. Besides these, the town can boast of several other handsome buildings. The railway to Paisley and Glasgow was opened in 1841. The line is 22½ miles in length. In 1828, a gas work was constructed at an expense of nearly L.9000, and being exclusively the property of the corporation, has hitherto been conducted with great advantage to the inhabitants. The West Parish church is a graceful and elegant structure. The Watt monument was erected in Union Street in 1838 to commemorate the genius of James Watt, who was born in Greenock. It is in the early English style of architecture, after a design by Blore, and has cost upwards of L.8000, of which the son of Watt contributed L.3000. It contains an exquisitely finished statue of the philosopher by Chantrey.

Within this building also is the public library, founded in 1783, and now containing upwards of 12,000 volumes. A mechanics' library was founded in 1832; and a mechanics' institution erected in 1840.

On the high ground between Greenock and Gourock stands the Wood Mariners' Asylum, a very handsome and extensive erection in the style of the Tudor period. It is the fruit of the generosity of the late commissary-general Sir Gabriel Wood, a native of Greenock, who died in 1845. It was founded for the benefit of decayed master mariners and seamen belonging to the various seaports on the Clyde. This building, which cost L.10,000, was begun in 1850, and opened in 1854. It provides accommodation for 50 inmates, although in the meantime only 25 have been admitted.

Greenock grammar-school was founded in the middle of last century. Its business was conducted in hired school-rooms till the present year (1855), when a handsome building in the old monastic style, erected by public subscription, was opened.

The Highlanders' Academy, a substantial and handsome building, was erected in 1836. There are various other educational institutions in Greenock adapted to every class.

The town is plentifully supplied with water, brought by an aqueduct 6½ miles in length, from an artificial lake in the neighbouring highlands, which receives the waters of a number of small streams. For several miles it runs at an elevation of 500 feet above the level of the sea, and in the vicinity of the town it pours down a torrent of water in successive falls, affording water-power to a number of mills erected on its course. There is also a compensation reservoir covering 40 acres of ground, besides other smaller basins: Also a series of self-acting sluices, constructed in a most ingenious manner, not only obviating all danger of an overflow, but preserving every drop of water even during the greatest floods. The whole of this magnificent public work, including two expensive filters, was planned by Mr Thom, an ingenious engineer, and executed under his directions at an expense of L.90,000.

The mill of the Shaws Water Cotton Spinning Company, erected in connection with the preceding works, was founded in June 1838, and opened in March 1841. It is an oblong building, 300 feet long, 65 wide, and 4 stories high. The centre portion projects, with a pediment on the top, surmounted by an octagon belfry. Each room is 215 feet long, and 61 broad, and the ceilings are supported by two ranges of cast-iron pillars, 20 in each. The wheel-house, which stands at a little distance from the main building, is 90 feet long and 33 broad. The base of the building is nearly 50 feet below, while the roof is about 35 feet above, the level of the road. The wheel itself is, in respect of its size and structure, unequalled in the world. It measures 70 feet 2 inches in diameter, or 220 feet 6 inches in circumference; the axle is of cast-iron, and weighs 11 tons; the centres or naves, into which the arms and braces are fitted with gibs and cutters, are 10 feet in diameter, and weigh 8½ tons each; the sole of the wheel is constructed of iron plates, fastened with 20,000 rivets; the buckets are 160 in number, and each contains 100 gallons of water; the wheel revolves once in a fraction more than a minute, and, with a full supply of water, is equal to 200 horse power. The weight of the whole is 117 tons. The spur wheel, with its shaft, weighs 23 tons, measures upwards of 18 feet in diameter, and revolves at the rate of 600 feet per minute. The wheel, with all its accompanying apparatus, was the workmanship of the late Mr Smith of Deanston. The mill, when fully engaged, occupies 600 hands.

A new cemetery, in the south-western part of the town, was opened in 1846. It contains upwards of 20 imperial acres, the carriage ways and walks alone considerably exceeding five miles.

On the high ground at the eastern end of the town, and commanding an extensive view of the river and adjacent country, stands the mansion-house, the old residence of the Schaw family. Adjoining this building lies the Well Park, an extensive piece of table-land overlooking the town, and inclosing the old well, on which is the date 1629. In 1851 this was generously given to the public by Sir M. R. S. Stewart. It is finely laid out with plants and evergreens, and forms an agreeable promenade ground. Another and larger park, the Wellington Park, has since been appropriated by the same donor exclusively to the use of the working classes; and here bowling, quoiting, and other athletic exercises, for which it has been adapted at the expense of the town, are zealously prosecuted.

Greenock is divided into three parishes, named respectively the Old or West, the Middle, and the East. The first church was built in 1591 on a piece of ground which at that period lay close to the shore. It was condemned in 1837. Its ruins now stand in the centre of a venerable burying-ground, near the spot where a part of the rebel forces raised by the Earl of Argyle landed in 1685. Within the burying-ground lie the remains of Burns' Highland Mary, and over the spot a public monument, bearing an appropriate inscription, was erected in 1842.

The New or Middle Parish was dissociated from the Old in 1741. The church, a plain but elegant edifice, was erected in 1757.

The East Parish was disjoined from the Old, and constituted a separate parish in 1809. The original church, which was built as a chapel of ease in 1774, was condemned in 1851, and a plain but elegant structure was erected by the town-council in 1853.

A church, containing nearly 1200 sittings, was built by subscription as a chapel of ease in the north-western part of the town in 1823, and subsequently designated the North Parish Church. Having stood empty since 1843, it has recently been sold, and is about to be converted into a public bazaar and hall for public meetings. There are also in Greenock 6 Free Church places of worship, 4 United Presbyterian, a Congregational, an Episcopalian, an Evangelical Union, a Roman Catholic, a Methodist, a Baptist, an Irvingite, and a Reformed Presbyterian chapel. A sailors' home, capable of accommodating 40 inmates, was opened in 1852. In connection with this there is a chapel containing 300 sittings, in which divine service is regularly conducted by a chaplain. Attached to the institution are a school, reading-room, library, and other advantages.

The manufactures of Greenock are various, but the principal are those immediately connected with the commercial interests of the port. Shipbuilding, of which there are seven large establishments, was introduced at an early period, and has largely increased of late years in connection with the use of iron in the construction of vessels. Four yards employ iron almost exclusively; and several of the largest steamers and merchant ships afloat have been built here. There is one patent slip which is large enough to admit a vessel of 400 tons register. Boat building is also extensively carried on; and in connection with these naval establishments are 2 sail-cloth factories, 5 rope-works, and 5 sail-making sheds. There are also several extensive engineering establishments, machine manufactories, and forges. Greenock is the chief seat of sugar-refining in Scotland, in which department there are 11 houses. In addition to the cotton mill formerly described, there are two woollen factories, a flax mill, a paper mill, 3 dyewood mills, 6 grain mills, 4 steam-saw mills, a distillery, 2 breweries, 5 tanneries, a pottery, several chemical works, and various other establishments common to large towns. The manufacture of straw-plait was extensively prosecuted for some years, but has gradually declined, and is now almost extinct. Letter-press printing was introduced in 1765, but the first book was not printed till 1810. There are 2 bi-weekly newspapers. During summer steamers arrive and depart from and to the principal places on the coast several times each day; there is also daily communication by steamboat with Liverpool, and various Irish ports. Trains run to and from Glasgow almost every hour, and the time occupied by express is 40 minutes. The philanthropic and benevolent institutions of the town are numerous, and comprehend various objects, domestic and foreign. A man-of-war is permanently stationed in the roadstead to receive volunteers for the navy.

The opposition to the monopoly of the East India Company originated with the merchants of Greenock in 1812, who were the first publicly to petition against that abuse. Greenock confers the second title of the noble family of Cathcart, who are descended from Marion, the only child of the last Sir John Schaw. The population in 1741 was 4100; in 1841, 38,846; in 1851, 39,391. (J. M. J.)

GREENWICH, a market-town of the county of Kent, in the hundred of Blackheath, within the lathe of Sutton, and five miles from London. It is situated on the south bank of the Thames, and extends along the shore of it. Though extensive, it is a single parish, and is at the present time well furnished with places of worship, having two large churches in the central part of the parish, and two others, one at the eastern and the other at the western extremity, besides other churches and chapels of the established religion, and several others belonging to various denominations of dissenters.

The most attractive object is the royal hospital for aged, decayed, or wounded seamen, built on a plan formed by Sir Christopher Wren, and devoted by William III. to this purpose. The building consists of four piles detached from each other, but so arranged as to form a complete square, open towards the river. The several divisions are occupied either as the residences of the governor or other officers; and there are a hall, a chapel, and apartments for the accommodation of the pensioners. The latter are appropriated for seamen, consisting of a cabin with a single bed, and a long gallery into which each cabin opens, where free air and recreation may be enjoyed. The hall is a magnificent apartment, decorated with excellent paintings on allegorical subjects connected with naval affairs, by Sir James Thornhill. This establishment has at present upwards of 3000 pensioners, besides between 5000 and 6000 others, called out-pensioners, who receive stipends at various rates. There is connected with it an infirmary, a school for several hundred boys, and other institutions, but without the walls. The pensioners are amply supplied with food, are well and uniformly clothed and warmly lodged, and are, besides, supplied with the sailor's most indispensable luxury, tobacco. The whole expense of maintenance is about L.26, 10s. a head, but varying with the fluctuation of the prices of bread, meat, and malt. See GREENWICH HOSPITAL.

Next to the Royal Hospital, the most remarkable institution is the Royal Observatory, primarily established in the reign of Charles the Second, for the advancement of navigation and nautical astronomy, but which has, since that time, under its successive able directors, Flamsteed, Bradley, Maskelyne, Pond, and Airy, won an unrivalled reputation for the excellence and variety of its observations, and for the advancement which it has given to all branches of astronomical science. Its organization at present is very complete, and it is enabled to take under its charge the

Greenwich Hospital.

control of magnetical and meteorological science, together with the transmission of time throughout England by means of electro-magnetic circuits, in addition to the usual work of an astronomical observatory. The chief astronomical instruments in use at present are a very large transit circle, and an altitude and azimuth instrument of sufficient firmness to produce lunar observations of first-rate excellence. To carry out the various details of the observations and processes employed, including the general use of photographic and electric manipulations, a large staff of assistants and computers is required, amounting on the whole to fourteen or fifteen persons.

The Park of Greenwich is an object of great attraction, and the hill behind commands a prospect over London and the plains of Essex. There are well-supplied markets on Wednesday and Saturday. It returns two members to parliament. In 1851 the population of the parish was 35,028, and of the parliamentary borough, 105,784.

Greenwich has always been famed for the excellence of its local charities, amongst which those most deserving of notice are—the Jubilee Almshouses, for the maintenance of a certain number of aged women; the Bluecoat Girls' School for boarding, clothing, and educating as many girls as the funds will allow; and the Bluecoat Boys' School. It has also two branches of the National School for boys and girls.

From the salubrity of the air and the beauty of the scenery around Greenwich, its neighbourhood has always possessed a great number of boarding schools and other educational institutions of a superior class. Of these may be mentioned a very large proprietary school for boys intended for commercial or professional pursuits.

Greenwich Park and Blackheath form the pleasure-ground of the population of London; and on every public holiday, especially at the two fairs held at Easter and Whitsuntide, a very large number of persons crowd to Greenwich by the steamboats, railroads, and other means of conveyance, partly to partake in the amusements that are to be found there, and partly, we may presume, to enjoy the fresh air and delightful views attainable from the Park and its neighbourhood. Under the metropolitan police regulations the good order uniformly preserved amongst so large a concourse of people is very remarkable; scenes of riot and confusion rarely occur; and nothing is needed but a little co-operation of the wealthier classes to render these periodical gatherings at Greenwich a source of profitable delight, as well as of mere amusement to the numerous visitors.

Greenwich Hospital is a royal foundation, erected by the munificence of William and Mary (originating, as is generally believed, with the queen), by letters patent of 25th October 1694. The hospital occupies the site of the old palace, called *Greenwich House*, which was from very early times a residence of our sovereigns. Edward III. had a palace there. Henry IV. resided much at Greenwich, and his will is dated from his manor of Greenwich. It was granted by Henry V. to the youngest son of John of Gaunt, and reverted again to the crown on his death (25th Henry VI.). Edward IV. took great delight in the palace, and enlarged it at much cost. He granted it to his queen, Elizabeth. It afterwards came into the possession of Henry VII., who enlarged and beautified it, and resided much there. Henry VIII. was at great expense to render the palace worthy of his sumptuous court. He called this his manor of pleazaunce, and held there many great banquets and royal ceremonies. Queen Elizabeth made many additions to the building, and resided much there. James I. laid the foundation of the *House of Delight*, which afterwards became the residence of the governor of the hospital. Charles I. resided frequently at the palace; and his queen furnished, with extraordinary magnificence, the building begun by his predecessor. At his death, it was taken possession of by the officers of the Commonwealth, who excepted it, for their own use, from the general ordinance passed 16th July 1649 for the sale of the crown lands; but upon their subsequent necessities for the support of the navy, it was ordered by the House of Commons, 27th November 1652, to be immediately sold for ready money. Preparations to give effect to this order were made, and some small part of the outbuildings was sold. The palace and park were, however (with other of the royal palaces), assigned by the House of Commons for the accommodation of the Lord Protector, and happily reverted to the crown on the restoration of Charles II., by whom the west wing of the present hospital buildings was added, as part of an extensive design. (Hasted's *History of Kent.*) The palace remained in the unfinished state in which Charles II. left it, when it was assigned by the patent of William and Mary to certain of the great officers of state, as commissioners for its conversion into an hospital for seamen. This was followed in the succeeding year by a patent, dated 10th September 1695, which recited that the object of the institution was to make some competent provision that seamen who, by age, wounds, or other accidents, should become disabled for further service at sea, and should not be in a condition to maintain themselves comfortably, might not fall under hardships and miseries, but might be supported at the public charge; and that children of such disabled seamen, and the widows and children of such seamen as should happen to be slain in the king's service, might, in some reasonable manner, be provided for and educated. The patent appointed Prince George of Denmark, several of the great officers of state, nobility, bishops, and others, to be commissioners for these purposes; and required them to consider how they might be best carried out, and the palace best converted for the charitable object to which it was assigned, and also to frame for his majesty's approval a charter of foundation. The government of the hospital has been continued in similar commissions in subsequent reigns, and the most distinguished persons have been appointed commissioners. George III., by his charter of 5th December 1775, incorporated the commissioners, vesting the goods and revenues of the hospital in them, and gave to them and their successors a perpetual succession.

Greenwich Hospital.

The revenues of the hospital have been derived from several sources. William III. contributed by grant L.2000 a-year towards perfecting the work, and authorized the commissioners to receive voluntary gifts and subscriptions in aid. Above L.50,000 had been expended, on Queen Anne's accession, upon the buildings, which though still very incomplete, were so far in a state of readiness that, in December 1705, 100 disabled seamen were taken into the hospital. On the 1st July 1708, the number amounted to 350, and the income was estimated at L.12,000 a-year; half of which was applied to the maintenance of the seamen, and the other half to the completion of the buildings.

By statute 7th and 8th Will. III., cap. 21 (1696), seamen in the royal navy and the merchant service were compelled to contribute 6d. per month from their wages to the support of the hospital, and the advantages of the institution were extended to both services. The latter, perhaps, did not receive their share of these advantages, for in the following year it was provided, by 8th and 9th Will. III., cap. 23, that, for avoiding all partiality and favour, any persons entitled shall be admitted in succession, one after the other, according to their priority of registration. But this did not last long, for we find it enacted in 1703 (2d and 3d Anne, cap. 6), that the admiralty shall thenceforth have full power to appoint disabled seamen and their widows and children, and the widows and children of seamen killed in the service, notwithstanding the provisions of the two preceding statutes in favour of the merchant seamen who made compulsory contribution to the support of the hospital. The funds of the hospital in its infancy were also supported by occasional grants. By 4th Anne, cap. 12, the queen was authorized to appropriate to its use L.6472, the proceeds of the goods of Kidd the notorious pirate. By 8th Geo. II., the forfeited estates of the Earl of Derwentwater, attainted of high treason (estimated to produce L.6000 a-year), were devoted to its completion and support; and by statutes of the same reign, six sums of L.10,000 were devoted to the same objects. Shares of prize money, of penalties in certain cases, percentage upon bounty money, upon freightage of treasure, and forfeited seamen's pay, were also assigned to the support of the hospital.

Within the last five years great changes have been made in the management of the hospital and its revenues. In 1825, by statute 5th Geo. IV., cap. 26, the Royal Naval Asylum (a school for the education of 800 boys, the children of seamen of the royal and the merchant navy) was consolidated in its government and funds with the hospital. In 1829 the corporation was dissolved by statute 10th Geo. IV., cap. 25, and the estates were vested in the treasurer of the navy, the first commissioner of woods, and three other persons named in the statute, whose appointments were during pleasure, and to whom the crown is empowered to appoint successors, while the lords of the admiralty assign their salaries. In 1834 the contribution out of seamen's wages was abolished, and in lieu thereof a sum of L.20,000 annually towards the support of the hospital was charged upon the consolidated fund.

The management of the civil affairs of the hospital is now vested in the five commissioners appointed under the above statute. Subject to the control and direction of the lords of the admiralty, they have power to make all contracts for the supply of the establishment, to execute all agreements, mortgages, and bonds relating to the corporate property, to grant leases, and to purchase, sell, and convey land. The governor of the hospital is charged with the maintenance of discipline and good order. The civil department consists of the five commissioners who are appointed by the crown on the nomination of the prime minister,—the two *ex-officio* commissioners receiving no salary, the other three L.600 a-year each—a secretary, clerks, and other officers. The military department consists of the governor, salary L.1500 a-year, lieutenant-governor, salary L.800 a-year, appointed in the same manner as the commissioners, four captains, four commanders, eight lieutenants, two masters, chaplains, surgeons, and other officers. With the above exceptions, all the appointments, civil and military, and the presentation to livings belonging to the hospital property, are in the gift of the first lord of the admiralty. The number of pensioners maintained in 1849 was 2710.

The revenue of the hospital in 1849 (for which year the latest accounts are printed) was—

Net produce of the estates	L.29,219
Rents in Greenwich	2,531
Interest on invested property	82,491
From consolidated fund, in lieu of merchant-seamen's sixpences	20,000
Freightage of treasure	10,406
Other small contingent receipts, including sale of L.3000 stock to purchase river frontage	3,736
	L.148,383

And the expenditure for the same year was—

Household and contingent expenses, comprising the maintenance, clothing, and allowances to 2710 pensioners and 97 nurses, with salaries and wages to the subordinate officers and servants, and all works and repairs	L.112,375
Charge for the royal naval schools	18,684
Parochial and assessed taxes	1,341
Annuity pursuant to 28th Geo. III., cap. 63, to Lady Newburgh	1,000
Purchase of river frontage and property for improvements	12,890
Other small charges	667
	L.146,957

It is stated that under the arrangements made pursuant to the acts of 1829 and 1834, the hospital surrendered L.42,000 a-year of its revenues.—(*Ho. Comm. Return*, 1850. No. 495.) (S. R.)

GREET, in England, a small picturesque trout river in the centre of Nottinghamshire. It rises in Jenkin's Carr, near Farnsfield, and falls into the Trent close by the village of Fiskerton.

GREGORIAN CALENDAR, one which shows the new and full moon, with the time of Easter, and the moveable feasts, by means of epacts disposed through the several months of the Gregorian year. See CALENDAR, vol. vi., p. 85–89; CHRONOLOGY, vol. vi., p. 668.

GREGORY I., called THE GREAT, elected Pope in 590, was born at Rome about the middle of the sixth century. His family was both wealthy and noble, and in his thirtieth year he was appointed prætor of Rome. He soon abdicated office, however; and on his father's death he surrendered his whole fortune to the church, building six monasteries in Sicily and one at Rome, to which he himself retired, intending for the future to lead a strictly ascetic life. Seeing one day some English slaves of striking beauty exposed for sale in the market, he suddenly cried out that their countrymen would be not "Angli" but "Angeli," if they were only Christians, and straightway formed the resolution of evangelizing Britain. He set out secretly on his mission; but his friends, who had been watching his movements, speedily brought him back. The Pope of that day, Pelagius II., then sent him on an embassy to Constantinople to beg assistance against the Longobardi who were threatening Rome. On Gregory's return from the Eastern capital, Pelagius died of the plague, and he was unanimously chosen to succeed him. He strongly deprecated the honour, and wrote to the Emperor Maurice imploring him not to confirm his nomination. A pious fraud committed by the city prætor then in office prevented these letters from reaching their destination; and though Gregory even hid himself for a time, he was at length obliged to yield to the instances of his friends and accept the Papal crown. As soon as he was seated on the throne he began with vigour the work of reform, and not only put an end to the corruptions and abuses that had been creeping into the church since the days of St Paul, but sent out his missionaries to the ends of the known world. In Lombardy he crushed the remains of Arianism; in Africa he weakened the sect of the Donatists; in Spain he effected the conversion of the monarch; and in England he gained many thousands of converts among all classes of the people. When John the Abstinent of Constantinople assumed the title of "Œcumenic Patriarch," Gregory protested strongly, alleging that the Pope himself had declined the title when offered him by the council of Chalcedon, and that for his part he gloried in being called the "Servant of God's Servants." On this principle he contented himself with advising the bishops without dictating to them. Though he was unweariedly zealous in propagating the gospel, he strictly abstained from using cruel or dishonest means to gain his end. He was perfectly tolerant of Jews and heretics; set a good example in liberating his slaves; and when master of all the wealth of the Roman see, remained till his death as austere an ascetic as when he was a simple deacon in the monastery of St Andrew. He died at Rome in 604.

Of Gregory's works the most important are his *Moralium Libri xxxv*, and his two books of homilies on *Ezekiel* and the *Gospels*; his *Letters*, which, as might have been expected, throw much light on the history of the times; and his *Dialogues*, in which are described the miraculous works of several saints—all related with the artless naïveté of entire belief. Some grave imputations have been cast upon Gregory, but, as is now known, on very insufficient grounds. He has been accused, for instance, of burning all the remains of ancient literature in the Palatine library. It is known, indeed, that he looked upon such works with suspicion, and forbade them to be read by the faithful; but the sacrilege attributed to him was not perpetrated till many centuries after his time, as is proved in the admirable *Art de Vérifier les Dates*. Equally unfounded is the charge brought against him of destroying the monuments of ancient Roman art, a crime which rather lay at the door of the countless pilgrims who used to visit the Eternal City. So far indeed

Gregory VII.

is this accusation from being true as regards Gregory, that he is known to have reprimanded Serenus, bishop of Marseilles, for having given over the images in his church to the iconoclasts, and to have charged the missionaries whom he sent forth, to preserve and purify the pagan temples.

Gregory VII., one of the greatest of the Roman pontiffs, was born, about 1013, at Soano in Tuscany, where it was said that his father was a carpenter. His own name was Hildebrand. He is first met in history as prior of the Abbey of Clugni, where he was held in high esteem for the depth of his learning, the sanctity of his life, and the severity of his self-discipline. Some services which he rendered to Bruno, bishop of Toul, who was on his way to Rome to take possession of the chair of St Peter (which he occupied under the title of Leo IX.), were the immediate causes of his rise. The grateful Pope made him a cardinal, sub-deacon of Rome, and superintendent of the convent and church of St Paul. Leo's successors, Victor, Stephen, Nicholas, and Alexander, were in reality nothing but tools in Hildebrand's hands, chosen by his influence to wear the insignia of the Papal rule till the time when he believed that he might himself assume them. At length, in 1073, the moment seemed favourable. Alexander died; and Hildebrand, as if in obedience to the tumultuous demands of the mob, was compelled, as it seemed against his will, to mount the vacant throne. But he refused to put on the tiara of St Peter without first obtaining the sanction of the Emperor of Germany. As soon as, by an act of adroit humility, he had gained this point, he was proclaimed Pope, by the title of Gregory VII. Once firmly established, Gregory determined to give practical effect to the two leading ideas of his life. The first of these was the reformation of the Church, whose ministers, especially in Germany and the north of Italy, had long practised simony without let or hindrance, besides leading grossly immoral lives. The second was the total emancipation of the Church from the interference of the civil power. In this way he saw that the sole right of distributing the valuable patronage of the Church would come to be vested in the Church herself. The latter of these ideas he determined to work out through the former, and a pretext for immediate action was not long wanting. One of the most flagrant of the sinners whom Gregory was bent on punishing was Henry IV. of Germany, a man of naturally fine qualities, but vain, licentious, grasping, and always in want of money. To meet the expenses of the wars he was constantly waging with his rebellious barons, he openly sold the most valuable sees in his empire to men whose only qualification was a round sum of ready money. Gregory, resolved on putting an end to the practice, first warned the emperor by letter; and, when no heed was given to his admonitions, sent legate after legate to bring the imperial sinner to reason. When these means failed, Gregory's next step was to assemble a council at Rome, in which it was resolved to excommunicate persons guilty of simony, to expel from the Church all married priests and such as were guilty of personal licentiousness, and not to admit into it as ministers any who would not take the vow of celibacy. Gregory foresaw the fierce opposition that would be raised to these measures, but he was inflexible, and his perseverance was finally rewarded with success. The most obstinate of his opponents was the young Emperor of Germany, and an occasion was not long wanting to bring them into open collision. Henry, holding in contempt the decrees and councils of Gregory, continued to exercise the patronage of the Church as before, and that not in Germany only, but in Italy. The see of Milan had become vacant, and the Emperor and the Pope both claimed the right of appointing a successor. While the dispute was still pending, Henry's Saxon and Thuringian subjects had broken out in open rebellion against the tyranny of their ruler, and were encouraged in their disaffection by Gregory. The Pope even went so far as to summon the German emperor to Rome, to answer before him for his sins towards his subjects. Henry's rage at this assumption knew no bounds. He summoned a diet of the leading clerical functionaries of his empire at Worms, declared Gregory deposed, announced this fact to the clergy at Rome, and took steps for appointing a successor to the dethroned pontiff. Gregory, undaunted, assembled his counsellors, excommunicated the emperor, and absolved his subjects from their oath of allegiance to him. Henry's tyrannies had raised a host of enemies against him; and, backed by the authority of the Pope, they convened to elect a new emperor. Resistance was in the meantime impossible, and Henry hurried away to Rome to make his submission and obtain pardon for his contumacy. In the dead of winter, and amid hardships that might have appalled the chamois-hunter, Henry crossed the Alps, attended only by his wife and a few followers. Gregory was in waiting for him at Canossa; but when his humbled and suppliant rival reached that town he refused to admit him into his presence for three days, and compelled him, though it was the depth of winter, and intensely cold, to spend the time in an outer court of the palace without shoes, and with no clothes but a single woollen garment. The Pope was at length pleased to absolve his royal penitent, who had no sooner left the Papal presence than he began to plot his revenge. Stung to madness by his humiliation, he threw himself on the generosity of his Lombard vassals, and, supported by them, recrossed the Alps, defeated his rebel subjects in several battles, and finally conquered and slew Rudolf of Suabia, who had been chosen emperor in his stead. Having restored his fortunes at home, he determined to take a signal vengeance on him whom he believed to be the cause of all his disgraces. In 1081 he entered Italy at the head of a powerful army, declared Gregory deposed, elected as his successor Guibert, bishop of Ravenna, and would have taken the Eternal City itself, had not the scorching heats of summer, and the advance of Robert Guiscard with his Normans and Saracens from Apulia, forced him to retreat. In each of the two following years he renewed his attack upon Rome, but he did not gain possession of it till, in 1084, the treachery of some of the inhabitants threw open the gates to him, when Gregory was obliged to take refuge in the castle of St Angelo. After being publicly acknowledged by the Romans, and establishing Guibert on the pontifical throne, with the title of Clement III., Henry determined to return to Germany, especially as the terrible Robert Guiscard was again at hand. Gregory, at length released from his confinement by the arrival of this freebooter, excommunicated Henry and Clement; but not deeming himself secure at Rome, he retired to Salerno, where he died in 1085. His last words were, "I have loved righteousness and hated iniquity, and therefore I die in exile." Hildebrand has been called by Guizot the Czar Peter of the Roman Catholic Church. On this illustration it has been remarked that the Czar wrought in the spirit of an architect who invents, arranges, and executes his own plan; Hildebrand, in the spirit of a builder, erecting by the Divine command a temple of which the Divine hand had drawn the design and provided the materials. His faith in what he judged to be the purposes and the will of heaven was not merely sublime but astounding. He is everywhere depicted in his own letters the habitual denizen of that bright region which the damps of fear never penetrate and the shadows of doubt never overcast. Could we accept this self-subordination as genuine, it would go far to redeem a character, formidable indeed as a whole, but presenting some weak, and it may be a few base points. But if we grant that it subsisted at all, it must be in a very different measure, and of a very different quality, from that noble faith which sustained Luther, or Cromwell, or Knox, or even

Gregory.

the higher spirits of Hildebrand's own Church, such as Xavier and others of his type. It was alloyed, too, with a large admixture of dross, such as found no place in the moral natures of the men we have just named. They could not, like him, act a part. They could not, as he often did, turn round from denouncing the terrors of the Church against recusants discreetly selected for their weakness to cringe and fawn upon the mighty of the earth. His conduct towards William the Conqueror, Philip of France, Robert Guiscard, and others that might be named, puts it beyond a doubt that he seldom allowed his principles to interfere with his interests. But though we may deny him the praise of integrity, truthfulness, and the higher kinds of courage, we must still admit him to have been perhaps, on the whole, the ablest of all the successors of St Peter. The amount of work which he did, and the imprint which he stamped upon the Church, will more than bear out this assertion. In the words of Sir James Stephen,—"He found the papacy dependent on the empire; he sustained her by alliances almost commensurate with the Italian peninsula. He found the papacy electoral by the Roman people and clergy; he left it electoral by a college of papal nomination. He found the emperor the virtual patron of the holy see; he wrested that power from his hands. He found the secular clergy the allies and dependants of the secular power; he converted them into the inalienable auxiliaries of his own. He found the higher ecclesiastics in servitude to the temporal sovereigns; he delivered them from that yoke to subjugate them to the Roman tiara. He found the patronage of the Church the mere desecrated spoil and merchandise of princes; he reduced it within the dominion of the supreme pontiff. He is celebrated as the reformer of the impure and profane abuses of his age; he is more justly entitled to the praise of having left the impress of his own gigantic character on the history of all the ages which have succeeded him."

Fifteen Gregories in all have occupied the chair of St Peter. The name is one well adapted for a Pope as the Watchman of Sion, being derived from ’εγρήγορα (the 2 p. a. of ’εγείρω), which signifies to keep watch, to be wakeful or vigilant. Of the fifteen by far the most eminent are the first and the seventh, whose lives have been given above in some detail. The second and third, whose reigns fell within the first half of the eighth century, became involved in unprofitable broils with the Longobards. The fourth came to the throne in 827, and is known from his efforts to patch up the quarrels between Louis le Debonnaire of France and his rebellious sons. The fifth and sixth were not remarkable either for their personal qualities or the events that took place in their reign; and the eighth was equally characterless. The ninth was noted for the uncompromising haughtiness of his views on the subject of the Papal supremacy, which involved him in serious collision with the Emperor Frederick II. of Germany. Open war soon broke out between the two potentates, the Pope being supported by his Guelphic partizans on the one side, and the Emperor, assisted by the Ghibelline faction, on the other. The tenth Gregory was respected in his day for some reforms which he effected in the discipline of the church; while the eleventh, whose name was Pierre Roger, though personally nowise remarkable, is noteworthy as being the last Frenchman that sat on the Papal throne. It was in the time of Gregory XII. that the schism which had divided the Roman Church since 1379, by the simultaneous reign of two popes, was brought to a close. Gregory XIII. is renowned for his learning, his liberal spirit, and his reformation of the Calendar in 1582. He had no share in the massacre of St Bartholomew, which happened during his reign; but he is believed to have countenanced the conspiracies against the life of Elizabeth of England. His successor was the famous Sixtus V. Little is known of Gregory XIV.; but the last of the name, Gregory XV., was renowned for his learning, his piety, and his gentleness, and also as the founder of the College de Propaganda Fide at Rome. He died in 1623.

Gregory of Nazianzum.

GREGORY *of Nazianzum* was born about the beginning of the fourth century. Both the exact time and place of his birth, however, have been disputed. His father, bearing the same name, became ultimately Bishop of Nazianzum, in the south-east of Cappadocia, from which the more illustrious son derives his surname. His mother Nonna, an eminently pious woman, appears to have exercised a powerful influence over the opening mind of her son. He was dedicated by her to the service of God from his birth; and, trained up under this consciousness, he is said to have early manifested strongly religious feelings, and to have even shown as a boy that ascetic tendency which marked his riper years.

In pursuit of a more liberal and extended culture than he could procure in the insignificant little town of Nazianzum, he went first of all to Cæsarea, the capital of his native province, and then successively to Cæsarea in Palestine, to Alexandria, and finally to Athens. Having embarked for Athens at an unfavourable season of the year, he very nearly perished in a storm. Here he renewed his acquaintance with Basil of Cæsarea, between whom and himself sprang up that warm and devoted friendship which has closely associated their names in the history of the Church. Here also he formed acquaintance with another person of a very different character, the prince Julian, destined afterwards to play so prominent a part in the world's history. This acquaintance has special significance in relation to the future conduct of Gregory. He seems thus early to have penetrated the true character of Julian, and to have imbibed towards him that hostility (for it can scarcely receive any milder name) which he afterwards strongly manifested.

Gregory remained at Athens for a lengthened period. He entered it when a youth, and only quitted it when he was about thirty years old. He returned to his father's house at Nazianzum; and being now for the first time baptised, he renewed on his own part his dedication to the service of religion. He still continued, however, for some time, and indeed more or less throughout his whole life, in a state of hesitation as to the special form in which he should apply himself to this service. Strongly inclined by nature and education to a contemplative and ascetic life, he was yet continually urged by circumstances to active pastoral labour. The monastic spirit clung to him through life, and never ceased to struggle for the ascendency. It was strongly encouraged by his correspondence with his friend Basil, who, after various travels, had betaken himself to a solitude in Pontus, and there gathered around him a group of like-minded devotees. It is this continually recurring desire for a monastic life that alone explains the vacillation and inconsistencies of Gregory's public career.

In the meantime circumstances, apparently accidental, determined his lot. The Emperor Constantius, by a course of artful intrigue and intimidation, having succeeded in thrusting an Arian formula upon the Western bishops assembled at Ariminum in Italy, attempted the same course with the Eastern bishops. The aged Bishop of Nazianzum having yielded to the imperial threats, a great storm arose among the monks of the diocese, which was only quelled by the influence of the younger Gregory. Shortly after, with a view to his permanent assistance, his father came forward before the assembled congregation, and unexpectedly ordained him to the priesthood. It appears to have been during this period of his life, while he continued as a presbyter in his father's diocese, that he distinguished himself by his opposition to Julian, and sent forth his two *Invectives* against that emperor. Subsequently he allowed himself to be nominated Bishop of Sasima, a small town between Nazianzum and Tyana. But he seems scarcely to have assumed his duties here, as we find him almost immediately again at Nazianzum, sharing there the episcopal duties, now grown too burdensome to his aged parent.

But a more important scene of duty awaited him. The small and depressed remnant of the orthodox party in Constantinople sent him an urgent summons to undertake the task of resuscitating the cause of truth, so long persecuted and borne down by the dominant Arians of the capital. With the accession of Theodosius to the imperial throne, the prospect of success to this cause was opened up, if it could only find some courageous and devoted champion. The fame of Gregory pointed him out as such a champion, and he could not resist the appeal made to him, although he took the step sorely against his will, and was even obliged to be dragged forcibly from his retreat. Here, amid many contentions, he laboured so zealously that the orthodox party speedily gathered strength; and the small chapel in which they had been accustomed to meet became extended into a vast and celebrated church, which received the significant name of Anastasia, or the Church of the Resurrection. It bespeaks the true Christian character of Gregory, that his first object was to awaken among his flock a loving Christian spirit, and not merely to build up and defend their doctrinal position. This also, however, he did, and with such powerful success in his five famous Discourses on the Doctrine of the Trinity, that he received the distinctive appellation of ῾Ο Θεολογος, "the Divine." He laboured in the Eastern capital till the arrival of Theodosius, and with this the triumph of the orthodox cause. The metropolitan see was then temporarily thrust upon him; but a spirit of discord and envy in reference to the promotion soon springing up in the episcopal council assembled by the emperor, Gregory resigned his dignity, and withdrew again into retirement. The remainder of his days he appears to have passed peaceably on his patrimonial estate near Arianzum. Here he devoted himself to his favourite studies—poems, discourses, and epistles, still extant (Edit. Morelli, Paris 1615), attest his diligence and activity as a student. The best account of his life and writings is to be found in the monograph of Dr Ullmann—*Gregory of Nazianzus; a Contribution to the Ecclesiastical History of the Fourth Century*, Darmst. 1825; Translated by G. F. Cox, M.A., Oxon. London; J. W. Parker, 1851. (J. T—H.)

Gregory *of Nyssa*, one of the fathers of the church, was brother of St Basil, and was born probably at Cæsarea in Cappadocia about A.D. 331 or 332. He received the best education that could be got at that time; and when of suitable years, married Theosebia, a lady whose virtues are highly extolled by her husband's friend and namesake of Nazianzus. After his marriage Gregory entered the church, but after holding for some time the office of a reader he once more devoted himself to the pursuits of secular life. However, the remonstrances of Gregory of Nazianzus led him to reconsider this step; and he was finally ordained by his brother, the great Basil, to the bishopric of Nyssa, a small town of Cappadocia. Here he adopted the opinion then gaining ground in favour of the celibacy of the clergy, and his wife became a deaconess in the church. His stern orthodoxy made him obnoxious to the Arian faction, then on the ascendant through the protection of the Emperor Valens; and in 375 he was driven into exile, whence he did not return till Gratian ascended the throne in 378. In the following year he took part in the council of Antioch, and was commissioned by the synod of that city to inspect the churches of Arabia and Jerusalem. The results of his journey and the shocking discoveries he made regarding the state of religion and morality, he published in a letter, in which he inveighed against the practice of pilgrimages to the holy city. At the second œcumenical council, held at Constantinople in 381, Gregory made himself conspicuous by his zeal against the Arians, and read his elaborate work in twelve books against Eunomius, in which he establishes the divinity and consubstantiality of the Word. It was chiefly through his means that the Catholic doctrine on the subject of the Holy Spirit was added to the Nicene Creed. The exact date of his death is unknown. Some authorities refer it to 396; others to 400.

Gregory's works may be classified under six heads,—1st, Treatises chiefly on doctrinal theology, with especial reference to the Arian heresies; 2d, Homilies; 3d, Sermons; 4th, Controversial writings, including the refutation of the Manichæans and Apollinarists; 5th, Biographies and Funeral Orations; and 6th, Letters. There have been numerous editions of some of Gregory's separate works, but the only complete edition of the whole works is that by Fronton du Duc, Paris, 1615; reprinted with additions in 1618; and again, though less correctly, in 1638.

Gregory, *Thaumaturgus*, or worker of miracles, whose Christian name was Theodorus, was born of heathen parents at Neocæsarea, in Cappadocia, in the third century of the Christian era. He was destined by his parents for the bar, and after studying at Athens, Alexandria, and Berytus, removed to Cæsarea in Palestine, where he became the pupil and finally the convert of Origen. On returning to his native town he displayed so much learning, piety, and zeal, that Phædimus of Amaseia, his metropolitan, resolved to consecrate him to the episcopate. Gregory long declined the honour, and even fled into the desert to escape Phædimus' importunities. At length he yielded, and (about A.D. 240) became bishop of his native town. He worked in this new sphere with so much zeal and success that, whereas at the outset of his labours there were only seventeen Christians in the city, there were at his death only seventeen persons who had not embraced Christianity. This result he achieved in the face of the Decian persecution and the inroads of the barbarians, who laid waste his bishopric A.D. 260. Gregory was strictly orthodox in his creed, and in 264 was present at the council of Antioch, convoked to investigate the heresies of Paul of Samosata. To him also was due the extirpation of Sabellianism throughout the province of Pontus. The miracles which he wrought, and which earned for him the surname of Thaumaturgus, are attested by Gregory of Nyssa and St Basil. They caused him to be venerated as a second Moses, and would be beyond the sphere of human credence unless certified by testimony which it is difficult utterly to reject. Gregory is believed to have died in the reign of Aurelian about the year 270, though some accounts place his death six years earlier. His principal works are his *Panegyricus ad Originem*, which he wrote when on the point of leaving Origen's school; *Expositio Fidei*, a summary of the doctrine of the Trinity; *Metaphrasis in Ecclesiasten*, criticised by St Jerome as "short but useful;" and an *Epistola Canonica*, for the benefit of those converts who had relapsed into paganism and desired to be once more admitted into the church. There have been several editions of Gregory's works, of which may be mentioned that of Gerard Voss, in Greek and Latin, Mayence, 1604; the Paris edition of 1622; and that contained in Galland's *Bibliotheca Patrum*, Paris, 1788.

Gregory *of Tours*, who may be called the father of French history, was born in Auvergne in 539, or, according to other authorities, in 544. His family was noble and powerful, and his uncle Gallus, or St Gal, who took care of his education, was Bishop of Clermont. At the age of 34 he already enjoyed a wide reputation for piety and wisdom in virtue of which he was appointed Bishop of Tours. The new bishop distinguished himself by his unflinching opposition to the ambitious designs of Chilperic, king of Soissons, whom, in his *Historia Francorum*, he denounces as the Nero of his age, while his royal spouse Fredegonda is hardly more gently dealt with. After governing his diocese with great ability and success during many years, he died in 593 at the age of 54.

Gregory's *History* is the work of a truthful, impartial, and enlightened observer of men and manners. His style is indeed not only barbarous in its Latinity, but feeble and devoid of colour or expression; his descriptions are lifeless, and his reflections commonplace. The information, however, which he conveys is valuable; and his work, which embraces a period of 174 years after the first establishment of the Franks in Gaul, throws abundance of light on the origin of the French nation. Besides his *History*, Gregory has left some other works on the glory of martyrs, the glory of the confessors, the miracles of St Martin, &c. The best edition of his works is that of Ruinart, Paris, 1699.

Gregory, the name of a Scottish family, of which many members have attained the highest eminence in various departments of science. The first who thus distinguished himself was David Gregory, son of the minister of Drumoak in Aberdeenshire, and elder brother of the inventor of the reflecting telescope. He is said to have been the first person in Scotland who possessed a barometer; and his curious experiments with this instrument led his ignorant and superstitious neighbours to suspect him of being in league with the devil. He was accordingly tried for witchcraft, but pardoned, as it was proved that he had never exerted his powers except for the good of the sick and poor in his vicinity. His son David, more famous than himself, was born in Aberdeen in 1661, and was educated partly in his native city and partly in Edinburgh. At the early age of twenty-three he became professor of mathematics in the university of the latter town, and was the first who openly taught the Newtonian philosophy in Scotland. In 1691 he was appointed Savilian professor of astronomy at Oxford,[1] and held that situation till his death in 1708.

David Gregory's principal works are his *Exercitatio Geometrica de dimensione figurarum*, Edinb., 1684; *Catoptricæ et Dioptricæ Sphæricæ Elementa*, Oxon., 1695; *Astronomiæ Physicæ et Geometricæ Elementa*, Oxon., 1702. This last is his greatest work, and was highly esteemed by Newton himself, of whose system it is an illustration and a defence. Besides these works we owe to Gregory an excellent edition of Euclid in Greek and Latin; and at the time of his death he was engaged, conjointly with his colleague Halley, in editing the Conics of Apollonius. A treatise of Gregory's on Practical Geometry, which he left in manuscript, was published in 1745 by the celebrated Maclaurin.

Of Gregory's four sons, the eldest, David, became regius professor of modern history at Oxford. He died in 1767, after having been for many years dean of Christ Church College in that university.

Gregory, *James* (1638–1675), one of the greatest names in modern mathematical and optical science, was the son of the minister of Drumoak in Aberdeenshire. He was born and brought up in the city of Aberdeen, and at an early period manifested a strong inclination and capacity for scientific pursuits. Before completing his twenty-third year he had published his famous treatise *Optica Promota*, in which is explained the principle of the reflecting telescope, which is still called by his name and widely used. After the publication of this work, Gregory lost some precious time in making experiments, and allowed Newton to share with him the glory of perfecting his great invention. In telescopes of moderate size, the original or Gregorian form is still in use; but in those vast instruments adopted by the Herschels the improvements of Newton have been found indispensable. About the year 1665 Gregory went abroad and studied for some years at Padua, where he published his *Vera Circuli et Hyperbolæ Quadratura*, in which he propounded his method of an infinitely converging series for the areas of the circle and hyperbola. When this treatise was republished in 1668, the author appended to it another, entitled *Geometriæ pars Universalis*, in which he laid down with great elegance and originality a series of rules for the transmutation of curves, and the measurements of their solids of revolution. These and his other works brought Gregory into correspondence with the leading mathematicians of that day, Newton, Wallis, Halley, and Huygens, with the last of whom he carried on a discussion on the subject of his treatise on the quadrature of the circle and hyperbola. On returning to England, Gregory was elected a member of the Royal Society, and finally became professor of mathematics at St Andrews in 1669. In that same year he married a daughter of the famous painter Jameson, whom Walpole pronounced the "Scottish Vandyke." In 1674 he was transferred to the chair of mathematics in Edinburgh, which, however, he only held for about a year, when in October 1675 he was suddenly struck with blindness, while showing the satellites of the planet Jupiter to some of his students through one of his telescopes, and died a few days after at the early age of 37. James Gregory, according to Dr Hutton in his *Philosophical and Mathematical Dictionary*, was a man of very acute and penetrating genius. His temper was in some degree an irritable one; and, conscious of his merits as a discoverer, he seems to have been jealous of losing any portion of his reputation by the improvements of others on his inventions. He possessed one of the most amiable characters of a true philosopher, that of being content with his position in life. But the most brilliant part of his character is that of his mathematical genius as an inventor, which was of the first order.

Among the other works of Gregory, besides those we have already mentioned, are his *Exercitationes Geometricæ*, Lond. 1668; and, it is alleged, *The Great and New Art of Weighing Vanity*, written to ridicule Sinclair, the slanderer of Boyle and Saunders, and published under the name of "Patrick Mathers, Archbeadle of the University of St Andrews." This latter, if it be really Gregory's, which is almost certain, is quite unworthy of its author.

Gregory, *Dr John*, professor of medicine in the university of Edinburgh, was the son of Dr James Gregory, professor of medicine in King's College, Aberdeen, and grandson of James, the inventor of the Gregorian telescope. His father was married first to Catharine Forbes, daughter of Sir John Forbes of Monymusk, by whom he had six children, most of whom died in infancy; and afterwards to Ann Chalmers, only daughter of the Reverend George Chalmers, principal of King's College, by whom he had two sons and a daughter. John, the youngest of the three, was born at Aberdeen on the 3d of June 1724. Having lost his father when only in the seventh year of his age, the care of his education devolved on his grandfather Principal Chalmers, and on his elder brother Dr James Gregory, who, upon the resignation of their father a short time before his death, had been appointed to succeed him in the professorship in King's College. He likewise owed much in his infant years, and indeed during the whole course of his studies, to the care and attention of his cousin, the celebrated Dr Reid, afterwards of the university of Glasgow. The rudiments of his classical education he received at the grammar-school of Aberdeen; and under the eye of his grandfather he completed, in King's College, his studies in the Latin and Greek languages, and in the sciences of ethics, mathematics, and natural philosophy. His master in philosophy and in mathematics was Thomas Gordon, professor of philosophy in King's College, who ably filled an academical chair for above half a century.

---

[1] On obtaining this professorship, he was succeeded in the mathematical chair at Edinburgh by his brother James, likewise an eminent mathematician, who held that office for thirty-three years, and when he retired in 1725, was succeeded by the celebrated Maclaurin. A daughter of this Professor James Gregory, a young lady of great beauty and accomplishments, was the victim of an unfortunate attachment, which furnished the subject of Mallet's well-known ballad of William and Margaret. In 1707, another brother, Charles, was appointed by Queen Anne professor of mathematics at St Andrews. This office he held with reputation and ability for thirty-two years; and, on his resignation in 1739, was succeeded by his son, who inherited the eminent talents of his family, and died in 1763.

In 1742 Mr Gregory went to Edinburgh, where the school of medicine was then rising into that celebrity for which it has since been so remarkably distinguished. Here he attended the anatomical lectures of the elder Dr Monro, of Dr Sinclair on the theory of medicine, and of Dr Rutherford on the practice of physic. He heard likewise the prelections of Dr Alston on the materia medica and botany, and of Dr Plummer on chemistry. The Medical Society of Edinburgh, instituted for the free discussion of all questions relative to medicine and philosophy, had begun to meet in 1737. Of this society we find Mr Gregory a member in 1742, at the time when Dr Mark Akenside, his fellow-student and intimate companion, was a member of the same institution.

In the year 1745 our author went to Leyden, and attended the lectures of Professors Gaubius, Albinus, and Van Royen. Whilst at this university he had the honour of receiving from the King's College of Aberdeen, his *alma mater*, an unsolicited degree of doctor of medicine; and soon afterwards, on his return from Holland, he was elected professor of philosophy in the same university. In this capacity he read lectures during the years 1747, 1748, and 1749, on mathematics, experimental philosophy, and ethics. In the end of 1749, however, he resigned his professorship of philosophy, his views being turned chiefly to the practice of physic, with which the duties of this professorship, occupying as they did a great portion of his time, too much interfered. Previously, however, to his settling as a physician at Aberdeen, he went for a few months to the Continent; a tour of which the chief motive was probably amusement, though to a mind like his certainly not without advantage in the enlargement of ideas, and an increased knowledge of mankind.

Some time after his return to Scotland, Dr Gregory married, in 1752, Elizabeth, daughter of William Lord Forbes, a young lady who, to the exterior endowments of great beauty and engaging manners, joined a very superior understanding and an uncommon share of wit. With her he received a handsome addition of fortune; and during the whole period of their union, which was only for the space of nine years, he enjoyed the highest portion of domestic happiness. Of her character it is enough to say, that her husband, in the admired little work, A Father's Legacy to his Daughters, the last proof of his affection for them, declares, that "while he endeavours to point out what they should be, he draws but a very faint and imperfect picture of what their mother was." The field of medical practice at Aberdeen being at that time in a great measure pre-occupied by his elder brother Dr James Gregory, and others of some note in their profession, our author determined to try his fortune in London. Thither accordingly he proceeded in 1754; and being already known by reputation as a man of genius, he found an easy introduction to many persons of distinction, both in the literary and polite world. Amongst these may be mentioned George Lord Lyttleton, who became his friend and patron. An acquaintance, which had been founded on a striking similarity of manners, tastes, and dispositions, grew up into a firm and permanent friendship; and to that nobleman, to whom Dr Gregory was accustomed to communicate all his literary productions, the world is indebted for the publication of the Comparative View of the State and Faculties of Man, which made him first known as an author. Dr Gregory likewise enjoyed the friendship of Edward Montagu and his lady, the celebrated champion of the fame of Shakspeare, against the cavils and calumnies of Voltaire.

In 1754 Dr Gregory was chosen fellow of the Royal Society of London; and as he made daily advances in the public esteem, it is not to be doubted that, had he continued his residence in the metropolis, his professional talents would have found their reward in an extensive practice. But the death of his brother, Dr James Gregory, in November 1755, having occasioned a vacancy in the professorship of medicine in King's College, Aberdeen, which he was solicited to fill, he returned to his native country in the beginning of the following year, and took upon him the duties of that office, to which he had been elected in his absence.

Here he remained until the end of the year 1764, when, urged by a laudable ambition, and presuming on the reputation he had acquired as affording a reasonable prospect of success in a more extended field of practice, he changed his place of residence for Edinburgh. His friends in that metropolis had represented to him the situation of the medical school as favourable to his views of filling a chair in that university; and this accordingly he obtained in 1766, on the resignation of Dr Rutherford, professor of the practice of physic. In the same year he had the honour of being appointed first physician to his majesty for Scotland on the death of Dr Whytt.

On his first establishment in the university of Edinburgh, Dr Gregory gave lectures on the practice of physic during the years 1767, 1768, and 1769. Afterwards, by agreement with Dr Cullen, professor of the theory of medicine, these two eminent men gave alternate courses on the theory and practice of physic. As a public speaker, Dr Gregory's manner was simple, natural, and animated. Without the graces of oratory, which the subject he had to treat in a great degree precluded, he expressed his ideas with uncommon perspicuity, and in a style happily attempered between the formality of studied composition and the ease of conversation. It was his custom to premeditate, for a short time before entering the college, the subject of his lecture, consulting those authors to whom he had occasion to refer, and marking in short notes the arrangement of his intended discourse; then, fully master of his subject, and confident of his own powers, he trusted to his natural facility of expression to convey those opinions which he had maturely deliberated. The only lectures which he committed fully to writing were those introductory discourses which he read at the beginning of his annual course, and which are published under the title of Lectures on the Duties and Qualifications of a Physician. Of these, which were written with no view to publication, many copies were taken by his pupils, and some from the original manuscript, which he freely lent for their perusal. On hearing that a copy had been offered for sale to a bookseller, it became necessary to anticipate a fraudulent, and perhaps a mutilated publication, by authorizing an impression from a corrected copy, of which he gave the profits to a favourite pupil. These lectures were first published in 1770, and afterwards in an enlarged and more perfect form in 1772.

In the same year, 1772, Dr Gregory published Elements of the Practice of Physic, for the use of Students; a work intended solely for his own pupils, and to be used by himself as a text-book to be commented upon in his course of lectures. In an advertisement prefixed to this work, he signified his intention of comprehending in it the whole series of diseases of which he had treated in his Lectures on the Practice of Physic; but this intention he did not live to accomplish, having brought down the work no further than to the end of the class of Febrile Diseases.

Dr Gregory became early a victim to the gout, which began to show itself at irregular intervals even from the eighteenth year of his age. His mother, from whom he inherited that disease, died suddenly in 1770, whilst sitting at table. Dr Gregory had prognosticated for himself a similar death; an event of which, amongst his friends, he often talked, but had no apprehension of the nearness of its approach. In the beginning of the year 1773, whilst in conversation with his son Dr James Gregory, the latter remarked, that having for the three preceding years had no return of an attack, he might expect a pretty severe shock that season; and he received the observation with some degree of anger, as he felt himself then in his usual state of health. The prediction, however, proved but too true; for having gone to bed on the 9th of February 1773, with no apparent disorder, he was found dead in the morning. His death had been instantaneous, and probably in his sleep; for there was not the smallest discomposure of limb or feature.

Gregory, *Dr James*, professor of the Practice of Medicine in the University of Edinburgh, and eldest son of the subject of the preceding notice, was born at Aberdeen in the year 1753, and there received the rudiments of his education. He accompanied his father to Edinburgh in 1764; and after going through the usual course of literary studies at Edinburgh, was for a short time a student at Christ Church College, Oxford, of which his relation Dr David Gregory had been dean. It was there probably that he acquired that taste for classical learning, and that admiration for the character of an accomplished classical scholar, which ever afterwards distinguished him. He entered early on the study of medicine at Edinburgh, and was a student in that faculty at the time of his father's sudden death, in February 1773. The extraordinary exertion which he then made to complete his father's course of lectures, was regarded by many of his friends as sufficient indication of his ability to continue and extend the hereditary reputation of his family. He took the degree of doctor of medicine at Edinburgh in 1774, and spent the greater part of the next two years in Holland, France, and Italy. It is worthy of notice, that his most intimate friend and companion on the Continent was Mr A. Macdonald, afterwards lord chief baron of the Court of Exchequer, in London.

After the death of Dr John Gregory, the chair of the Institutes of Medicine (then finally separated from that of the Practice of Medicine, of which Dr Cullen remained professor) was offered to Dr Drummond, who was at that time abroad, and who ultimately declined accepting it. For two winters the class was taught by Dr Duncan, whose appointment, however, was only temporary. In 1776 the chair was again declared vacant, and on the 1st of August of that year Dr Gregory was appointed professor. He began to lecture on the Institutes the next winter session, and in the succeeding year he commenced also the duty of teacher of Clinical Medicine in the Royal Infirmary, and continued to deliver at least one course of clinical lectures annually, for more than twenty years.

From the time of commencing his duties as professor Dr Gregory was continually engaged in medical practice; but his practice amongst the higher ranks of society was not extensive until many of his pupils had been settled in business, and were desirous of availing themselves of his assistance. For the last twenty-five years of his life he was much engaged in consulting practice; and for the last ten he was decidedly at the head of his profession in Scotland. Indeed, the boldness, originality, and strength of his intellect, and the energy and decision of his character, were so strongly marked in his conversation, that, wherever his professional character was known, it could hardly fail to inspire general confidence.

In 1778 he published his *Conspectus Medicinæ Theoreticæ*, as a text-book for his lectures on the Institutes. This work passed through several editions, both during his lifetime and since his death, and has been very generally admired, partly on account of the accurate view which it affords of the state of medical science at the period when it was composed, and partly for the ease, perspicuity, and elegance of its Latinity. The greater part of the work is occupied by the principles of Therapeutics; and as it must be confessed that there has been less improvement since that time in the investigation of the powers of remedies, than of the principles either of Physiology or Pathology, that portion of it may still be studied with advantage by all medical men.

On the illness of Dr Cullen in 1790, he was appointed joint-professor of the Practice of Medicine; he became sole professor on the death of Dr Cullen in the same year; and continued to deliver lectures on that subject, to audiences almost regularly increasing, until his last illness in 1821. He died on the 2d of April of that year.

As a practitioner and teacher of medicine, it may be stated that Dr Gregory was chiefly distinguished by his clear perception, and constant application, of the truth contained in a maxim which he was accustomed to quote from a favourite Greek author: "The best physician is he who can distinguish what he can do from what he cannot do." He distrusted all theories in regard to the intimate nature of diseased actions, as premature and visionary; but he had early and carefully studied the diagnostic and prognostic symptoms, and the various forms of the most important diseases, and the agency of the most powerful remedies; and, without entering into the minutiæ of morbid anatomy, he had a clear understanding of the changes of structure to be apprehended from disease in the different internal parts of the body. On these points, and their immediate practical bearing, he fixed all his attention. When he thought that these changes were approaching, and could be arrested by active treatment, he urged the truly effectual remedies with the peculiar energy of his character; restrained only by his strong good sense and ample experience, and despising all parade of nicety, or variety of prescription. When he was satisfied that the nature or the stage of the disease did not admit of effectual cure, his decision of character was equally shown in abstaining from useless interference, and confining his views to the relief of suffering.

As a teacher, he was always strongly impressed with the duty of fixing the attention of his pupils on those points in the history of disease, and in the application of remedies, the knowledge of which he had found by experience to be most practically important, and the ignorance of which he thought practically dangerous. The characteristic symptoms and varieties of inflammatory diseases, and the extent to which the antiphlogistic treatment might be carried in opposing them, were, therefore, subjects on which he dwelt with peculiar earnestness; and in regard to the use of those remedies in such diseases, he had acquired, by long and keen observation, a *tact* and decision which probably were never surpassed. On the other hand, in regard to those numerous chronic diseases, where *remedies* are so frequently ineffectual, he was equally zealous in inculcating those means of *prevention* which he thought most effectual and most attainable; and whilst he was incredulous as to the alleged virtue of most medicines in such diseases, he omitted no opportunity of illustrating the efficacy of temperance, even of abstinence, of bodily exertion without fatigue, and mental occupation without anxiety, in averting their approach, or even arresting their progress. From these great practical objects of his labours as a teacher, no consideration ever turned him aside. His extensive reading, particularly of the older authors, never led to pedantic displays of learning; his logical acuteness never beguiled him into useless controversies; his fertility of imagination never carried him beyond the simplest and most practical views of the subjects of which he treated.

As a lecturer, he possessed the great advantages of a command of language, which made him almost independent of any written notes, and of a tenacity of memory which enabled him to detail cases, in illustration of his principles, year after year, from the whole range of his experience, merely from having the names of the patients before him, without the slightest inaccuracy or omission. The commanding energy and quickness of intellect which his lectures displayed, the frank and fearless exposition of his opinions which they contained, the classical allusions with which they abounded, and the genuine humour by which they were often enlivened, rendered them peculiarly attractive and interesting, and acquired for him a remarkable ascendency over the minds of his pupils.

In the practice of the profession he was remarkable for the frankness and candour of his communications with the relations and friends of the sick; and for the zealous and even tender interest, always increasing with the difficulty and danger of the case, which he took in his patients. This made the more impression, as it contrasted with a certain roughness of external manner, and a constitutional hilarity and whimsical humour, which on some occasions, it must be owned, like that of a celebrated fictitious character, made him "not hesitate between his friend and his joke."

His conduct with his professional brethren in consultation was eminently distinguished by candour and liberality, and the total absence of all professional trick. He never attempted to make himself of importance, but was ever ready to give the strongest commendation to the treatment previously pursued, when he thought it judicious; always laying stress on the great and essential points of practice, and never giving an undue importance to favourite nostrums, or remedies of a secondary or frivolous kind. Thus the young practitioner, who was attentive to his duties, and honourable in his conduct, always found in him a zealous friend; those only had to dread coming into collision with him, who were wanting in professional zeal or professional integrity.

Dr Gregory's more intimate friends and connections were strongly attached to him on account of the warmth and steadiness of his attachments, of a generosity of disposition bordering on profusion, and of a high and somewhat aristocratic sense of honour, which made him instinctively shrink from any proceeding liable to the slightest imputation of meanness, selfishness, or duplicity.

He had therefore an utter detestation for all those professional arts by which the favour of the public is sometimes too successfully propitiated; and this was the true origin of various controversies in which he was at different times engaged with his professional brethren, and to which his strong sense of humour, his fondness for logical disputation, and (it must be confessed) a somewhat irascible temper, led him to devote more of his time and attention than their importance deserved. For the interests of the Medical School, and of the medical profession of Edinburgh, the continuance of these disputes was a matter of serious regret; but the feelings which led him to engage in them were too well understood and appreciated, to permit them to occasion him any loss, either of private friendships or of public estimation.

No medical teacher or practitioner of eminence was ever more ready to acknowledge the imperfection of his art, more distrustful of medical theories, or even of the alleged results of medical practice, when not in accordance with his own experience; or more careless of posthumous reputation. But none was ever more solicitous to give, both to his pupils and his patients, the full benefit of those principles of medical science, of the truth and importance of which he was himself convinced; and on this account his professional character had assumed, long before his death, a superiority over most of his contemporaries, of which those who judge of it only from his own contributions to medical science or literature cannot form an adequate conception.

Dr Gregory used to say, that whilst physic had been the business, metaphysics had been the amusement, of his life. Of this predilection we have a highly honourable testimony, in Dr Reid's Dedication to him and to his illustrious friend Mr Dugald Stewart, of his *Essays on the Intellectual Powers*, published in 1785; and, at a much later period of his life, in the cordial friendship which united him with the late Dr Thomas Brown, and the warm interest which he took in the appointment of that eminent metaphysician to the Chair of Moral Philosophy, on Mr Stewart's resignation of it, and retirement from the University. It is proper to add, however, that on some important metaphysical questions the opinions of Dr Brown were different from those of Dr Gregory, and probably never were the subject of discussion between them.

His own metaphysical and literary works are, *A Theory of the Moods of Verbs*, published in the Edinburgh Philosophical Transactions for 1787; and his *Literary and Philosophical Essays*, in two volumes, published in 1792. The main object of the latter work was to explain and defend a new argument on the old controversy as to the liberty or necessity of human actions; and whatever may be thought of the soundness of the argument, no one has ever disputed the acuteness and power of logical reasoning which he displayed in defence of it. It must be admitted, however, that his ideas of metaphysical inquiry were in some respects limited. He regarded metaphysics rather as a field for syllogistic reasoning, than as a subject of inquiry directed to the establishment of general principles by induction; and one of his favourite doctrines, that metaphysics admit of no *discoveries*, if admitted as literally correct, would almost imply that the study can lead to no useful practical results.

He retained throughout life a fervent admiration for the classical authors, and a severe and somewhat fastidious taste in literature, which was formed on the classical models. Several of the lighter and controversial writings with which he amused himself, particularly his Memorials on certain changes in the arrangements of the Royal Infirmary in 1800 and 1803, exhibit very numerous examples of his ready recollection and happy application of quotations from the classics; and a number of Latin epitaphs and inscriptions of various kinds, which he composed at different periods of his life, attest an accuracy of knowledge of the Latin language, and a purity of taste in Latin composition, which few men have the faculty of retaining throughout a lifetime of incessant professional labour.

Dr Gregory was married in 1782, to Miss Mary Ross; but within a few months after her marriage, this lady, to the extreme regret of all her friends, became decidedly consumptive, and survived only two years. After her death her two sisters continued to reside with their brother-in-law, until they both successively sunk under the same cruel disease. In 1796, he married one of the daughters of the late Mr M'Leod of Geanies, by whom he had a large family. His second son devoted himself with zeal and ability to the profession of medicine. He had entered on practice, had already been placed in several responsible situations in Edinburgh, and distinguished himself by some papers on medical subjects, when he was unfortunately carried off by a fever contracted in the course of his duties in 1832. (W. P. A.)

GREGORY, *Olinthus*, LL.D., was born in 1774 at Yaxley in Huntingdonshire. He first acquired distinction through his *Treatise on Astronomy*, and by his *Pantologia*, a sort of cyclopædia of the arts and sciences which he edited. In 1802 he was appointed mathematical master, and, some years later, professor, in the Military School at Woolwich, where he remained till 1838, when bad health compelled him to retire. During this long period of time he published a number of works, some of them of considerable value, such as his *Elements of Plane and Spherical Trigonometry; Mathematics for Practical Men; Letters on the Evidences of Christianity*, &c. His work on *Mechanics* is a good popular treatise on the subject, and one that has proved very valuable to many artizans whom want of mathematical knowledge has debarred from the perusal of more scientific works. Dr Gregory died in 1841.

GREIFFENBERG, a town in the Prussian province of Pomerania, and government of Stettin, on the Rega, 45 miles N.E. of Stettin. It is the capital of a cognominal circle, the seat of a court of justice, and has important manufactures of woollen and linen cloths, hats, and leather. Pop. (1849) 4975, including the military. There are several smaller towns of this name in Germany.

GREIFFENHAGEN, a town in the Prussian province of Pomerania, and government of Stettin, on the Reglitz, 12 miles S.S.W. of Stettin. It is the capital of a cognominal circle, the seat of a court of justice, and has manufactures of woollen and linen cloths, breweries, distilleries, fisheries, and some trade. Pop. (1851) 5591.

GREIFSWALD, or GREIFSWALDE, a town in the Prussian province of Pomerania, and government of Stralsund, on the Ryck, 3 miles from its mouth, in the Baltic, and 20 miles S. by E. of Stralsund. It is pretty well built, and is surrounded by promenades formed out of its old ramparts. It is capital of a cognominal circle, and the seat of several judicial tribunals. A university was founded here in 1456, but the number of students is inconsiderable, being in 1850 only 189. It has also a botanic garden, observatory, gymnasium, &c. There is a good harbour for small vessels at the mouth of the Ryck, and an active coasting-trade is carried on. It has building-docks, distilleries, salt-refineries, oil-mills, soapworks, and tobacco manufactories. Pop. (1849) 12,715, besides 524 military.

GREIZ, or GREITZ, a town of Germany, capital of the principality of Reuss-Greitz, in a valley on the right bank of the Elster, near the borders of Saxony, and 14 miles W. by S. of Zwickau. It is surrounded by walls, and is tolerably well built. It has a Latin, a normal, and other schools, and is the seat of the government and of a judicial consistory. The prince's palace occupies a hill adjoining the town, and is surrounded by fine gardens. Its manufactures are considerable, chiefly of woollen and cotton cloths. Pop. about 7000.

GRENADA (or rather GRANADA), the most southern of the Antilles, lies between N. Lat. 11. 58. and 12. 20., and W. Long. 61. 20. and 61. 35., being 60 miles N.W. of Tobago and about the same distance from the nearest point of South America. It is 25 miles in length from N. to S., and its greatest breadth is 12 miles; area 133 square miles. Grenada was discovered by Columbus in 1498, and at that time it was inhabited by a numerous and warlike race, the Caribbs. The Spaniards did not attempt to form a settlement, and the Caribbs remained in undisturbed possession of their territory until the year 1650, when Du Parquet, the French governor of Martinique, organized an expedition, consisting of 200 adventurers, for the purpose of seizing the island. These were received with the utmost kindness; and the few knives, glass-beads, and other trinkets presented to the natives, they subsequently asserted to be the price paid for the island. This afforded them a pretext for commencing hostilities against the Caribbs; and Du Parquet, who had returned to Martinique, sent a reinforcement of 300 men with orders to extirpate the natives altogether. The greatest cruelties were practised on the unfortunate natives—not even the women and children were spared. Father Du Tertre mentions that on one occasion "forty of the Caribbs were massacred on the spot. About forty others who had escaped the sword, ran towards a precipice, from whence they cast themselves headlong into the sea, and miserably perished." In a few years the island became vested in the crown of France; but for a long time the colony remained in a state of poverty and depression, so that, according to Abbé Raynal, the island in 1700 contained only 251 whites, and 525 blacks, who were employed on 3 plantations of sugar, and 52 of indigo. Subsequently the French turned their attention more particularly to their colonies, and Grenada rapidly increased. In 1753 it contained 1262 whites, 175 free blacks, 11,991 slaves, and 83 sugar plantations. Grenada surrendered on capitulation to Britain in 1762, and was formally ceded to that country by the definitive treaty of peace which took place in the following year. Certain stipulations were made in favour of the inhabitants; but the island does not seem to have prospered, and was retaken by the French in 1779. By the general peace, which took place in January 1783, it was restored to Britain, of which it has since been a dependency, although an insurrection of the slaves which took place towards the close of the last century is said to have been fermented by the French for the purpose of again obtaining possession of it.

Grenada is in general mountainous and picturesque. The interior and north-west coast consist of continuous ridges of hills rounded in their outline, and covered with vast forest trees and brushwood. An irregular but continuous range of mountains traverses the island from north to south, and in some parts rises to the height of 3000 feet above the level of the sea. From these several lesser ridges branch off, and form rich and picturesque valleys. The geology of the island is very complicated and irregular. The great mass of the mountains and some parts of the low lands consist of red and gray sandstone, greywacke, hornblende, and argillaceous schist; but the strata are very much diversified, being in one place horizontal, in another vertical, and in almost all suddenly and abruptly intersected by each other. Sulphur and fuller's earth are common; and porphyry, limestone, and basaltic rocks occur in certain places. The rivers are numerous but not large. In the centre of the island, and 1740 feet above the level of the sea, is the *Grand Etang*, a circular lake 2½ miles in circumference and 14 feet deep. Several hot chalybeate and sulphurous springs are met with in different parts. Along the coast are numerous excellent bays and harbours. The waters abound with fish; and game and various species of birds are abundant. Hurricanes are comparatively mild and unfrequent, but shocks of earthquakes are sometimes experienced. The medium temperature throughout the year is estimated at 82° Fahr. in the low country, but in the more elevated parts it is, of course, lower. A considerable quantity of rain falls, and throughout the year showers are frequent. Of late years the climate has been materially improved. The soil consists principally of a rich black or reddish coloured mould. The chief products are sugar, cocoa, coffee, and cotton; indigo and tobacco are also raised, together with luxuriant crops of fruits and vegetables, which grow here in great abundance and arrive at high perfection. In 1853, 17,722 acres were under cultivation. Grenada is divided into six parishes—St Patrick, St Andrew, St John, St Mark, St David, and St George. In the last of these is the capital

St George or George Town, which is built upon a peninsula projecting into a spacious bay on the west or lee side of the island, not far from the southern extremity. It is embosomed in an amphitheatre of hills, and stands principally on elevations which rise from the bay, and consequently the streets are steep. The houses are well built of brick or stone, and on the whole the town has a handsome appearance. It is divided by a ridge running into the sea, and forming on one side the Carenage, a large basin of water, surrounded by wharfs and stores. Here the ships lie land-locked and in deep water close to the wharfs. The entrance is defended by a citadel called Fort George, which stands upon a rocky eminence. On the left the land rises gradually to some height, the summit being crowned by the fortifications of Hospital Hill; and a long ridge, which falls towards the middle, connects this fort with Richmond Heights which constitute the background of the scene, and which are also fortified. The ridge which connects Fort George with Hospital Hill also separates the Carenage from the larger portion of the town, which contains the market-place and looks upon the bay. Upon this hill are built some of the principal houses of the town, the church, and the parsonage. At its extremity is the court-house, and nearly opposite is the Catholic chapel. Besides the Carenage there is another spacious sheet of water called the Lagoon, which is separated from the former by a reef passable only by boats. Among the public buildings of George Town are the court-house, a fine and commodious building, the jail, the church, a handsome building with a spire and clock, the Roman Catholic chapel, and the custom-house. The market-place is a square piece of ground of considerable dimensions, surrounded by houses, and having a public fountain. Pop. (1851) 4567. The other towns are unimportant.

Between St Vincent and Grenada there is a cluster of small islands called Grenadines, some of which are dependencies of Grenada. Of these Cariacou is the most important. It is about 19 miles in circumference, and contained, in 1851, 4461 inhabitants. The principal town is Hillsborough. It is fertile and well cultivated, but suffers occasionally from long-continued drought. Cotton was formerly the chief article of cultivation, but sugar is the staple article now raised.

The following return shows the different products of Grenada and the Grenadines in 1853:—Sugar, 11,293,851 lbs; rum, 326,808 galls.; molasses, 19,972 galls.; cocoa, 9318 lbs.; cotton, 73,633 lbs. The imports from Great Britain during that year amounted in value to L.71,981; from British colonies to L.44,181, and from foreign countries to L.22,898,—total L.139,060. Exports to Great Britain, L.104,432; to British colonies, L.14,289; to foreign countries, L.5234,—total, L.123,955. In 1853 the total revenue was L.15,038, L.9471 being custom duties, and L.5567 assessed and other taxes; and the expenditure, L.17,130, being—civil government, L.4122; judicial, L.820; ecclesiastical, L.2478; education, L.1097; police, L.2358; prisons, L.390; and miscellaneous, L.5865. In that year the revenue was L.2328 less, and the expenditure L.236 more, than in the preceding year. The population in 1851 was 32,671, of which 15,713 were males, and 16,958 females. In 1853 it was estimated at 34,077. There were then 11 Episcopalian churches, and 16 belonging to other denominations, with an average attendance of 11,916. The number of scholars attending Episcopalian schools was 967, other schools 1057. Crimes and offences—44 felonies, 50 misdemeanours, and 120 other offences.

GRENADE, in *Artillery*, a kind of small shell which, as soon as the fuze is lighted, is projected by the hand. It weighs about 1 lb. 13 oz., and is chiefly used for throwing into the ditch or covered way from the parapet. Grenades were first used in 1594.

GRENADIER, originally denoted a soldier who threw the grenade; but the term *grenadiers* came afterwards to be applied to certain troops of the line, distinguished from the latter chiefly by a high cap and some other peculiarities of dress. The term originated with the French, in 1667. In the infantry regiments of most European armies, the tallest and finest-looking men are selected to form a company of grenadiers who occupy the right of the battalion when in line, and lead in attack.

GRENOBLE (the ancient *Gratianopolis*), a fortified city of France, formerly capital of Dauphiné, now of the department of Isère, is pleasantly situated on the Isère, just above its confluence with the Drac, in a basin surrounded by lofty mountains, 58 miles S.E. of Lyons. The city proper, or larger portion, occupies the left bank of the river, and is connected with the opposite bank by two bridges, one of stone, the other an iron chain bridge. This portion of the town is surrounded by bastioned ramparts, and has a citadel; it contains several good squares, and the houses are three or four storeys in height, with flat, tiled roofs; but the streets are narrow, though well paved and regular. The portion on the right bank, called the Faubourg St Laurent, consists chiefly of one spacious street, immediately behind which rises an abrupt mountain studded with fortifications to the height of 918 feet above the river. From the summit of this mountain an extensive view of the surrounding country is obtained. This part of Grenoble was formerly surrounded by an ancient wall, which has recently been demolished, and its place is now occupied by a fine promenade. The river is bounded on both sides by handsome quays, along which extend lines of elegant houses. This town has been much enlarged and improved of late years; and it is proposed to extend it considerably, and reconstruct the fortifications so as to inclose a much larger space of ground. The public buildings are not remarkable. The cathedral is a heavy, ungainly structure, partly ancient and partly modern. There are several public walks and handsome fountains. The court-house is the most interesting old building in the town, having been originally the palace of the dauphin. One of the most pleasing features of the town is its extensive and well laid out public garden, on the left bank of the Isère. In the Place St André is a bronze colossal statue of Bayard the "*chevalier sans peur et sans reproche*," who was interred in a contiguous church. It has a public library, with 60,000 vols.; a college; museums of natural history and antiquities; a picture gallery; botanic garden; schools of medicine, artillery, and design; and societies of agriculture, science, art, &c. The chief manufactures are kid gloves, for which it is specially noted; chamois and other leathers; liqueurs, &c. It has some trade, by means of the river, in hemp, iron, timber, and marble. Grenoble occupies the site of the ancient Cularo, the name of which was subsequently changed to Gratianopolis in honour of the Emperor Gratian. This was the first place that openly received Napoleon on his return from Elba in 1815. Pop. (1851) 26,852.

GRENVILLE, LORD. See WYNDHAM, *Right Hon. William*.

GRENVILLE, *Richard*, Earl Temple, the most distinguished of a family of English politicians, was the eldest son of a country gentleman of the same name, who possessed the estate of Wotton, in Buckinghamshire. This Richard Grenville of Wotton was married to Hester Temple, a lady who succeeded to the title and estates of Lord Cobham, to whom Pope inscribed one of his epistles. Their son, the future Lord Temple, was born in 1711; and he partly owed his introduction to public life to the circumstance that his sister, Hester Grenville, was married to the celebrated William Pitt, afterwards Lord Chatham. When Pitt was, in 1755, dismissed from his office of paymaster of the forces, Lord Temple generously made him a present of L.1000. In the following year Pitt was secretary, and Temple was made first lord of the admiralty. In 1757

Grenville.

he was lord privy seal. He had various differences with his illustrious relative, and was latterly a sort of leader in opposition; but he ultimately retired from politics, and devoted himself to the embellishment of his seat of Stowe, so famed for its magnificence. He died in 1777. Mr Macaulay characterizes Temple as possessing no high talents for administration or debate, but as being formidable on account of his great possessions, his turbulent and unscrupulous character, his restless activity, and his skill in the most ignoble tactics of faction. Since Mr Macaulay wrote, the "tactics" of Earl Temple have received a new and interesting illustration. In 1852 were published *The Grenville Papers;* being the correspondence of Earl Temple and his brother, George Grenville, their friends and contemporaries. This correspondence—long known and mentioned as the "Stowe Papers"—commences in 1742, and terminates in 1777. It is important as explaining many of the political movements of the day, and exhibiting the sovereign, George III., in private communication with his ministers. The papers were believed to contain a solution of the mystery connected with the authorship of *Junius' Letters*, but this they failed to accomplish, though containing many interesting particulars relative to that curious and well-kept secret. Mr W. J. Smith, editor of the *Grenville Papers*, endeavours to establish the claim of Earl Temple to be Junius. The necessary information Earl Temple undoubtedly possessed, and Mr Smith assumes that Lady Temple was his amanuensis and assistant: "She had talent enough to assist him in the composition of his writings, and her praise was sufficient to support his vanity." The handwriting of this lady, it appears, bears a striking resemblance to that of Junius. Now, it is certain that the statements of Junius, made in his private communications to Woodfall, printer of the *Public Advertiser*, are not always consistent. He declared that he was the sole depositary of his secret, and that it should die with him; yet he writes to Woodfall—"The truth is, there are people about me whom I would wish not to contradict, and who would rather see Junius in the papers, ever so improperly, than not at all." On another occasion he speaks of the gentleman who manages the conveying department of the letters between himself and Woodfall. Junius also boasts of being above a common bribe, and asserts that he is a man of rank and fortune—assertions which seem to countenance the supposition that Earl Temple might be the author. But, militating against this theory, and against Junius' own assumption of superiority of position, is the information contained in three letters first published in this very work, the *Grenville Papers*. In 1768, before the writer had adopted the signature of Junius, he addressed private communications to Earl Temple, professing the warmest respect for his character and public spirit, and offering hints on political questions. The first relates to a report that Lord North was to introduce into his budget a tax of threepence in the pound on all articles sold by auction. In this letter, "C," or Junius, says—"It is not necessary or proper to make myself known to you at present; hereafter I may, perhaps, claim that honour." In the second letter he avows himself to be the author of papers signed "Lucius," but assures Earl Temple that he (the writer) "is a man quite unknown and unconnected," who had attached himself to the earl's cause, and to him alone, upon motives which, if he were of consequence enough to give weight to his judgment, would be thought honourable, &c. He adds, that at a proper time he would solicit the honour of being known, but that he had then important reasons for wishing to be concealed. The third letter is to the same effect. The writer states that a satire on the ministry, entitled "The Grand Council" (published in Woodfall's *Junius*) proceeded from his pen, as had "almost everything that, for two years past, attracted the attention of the public." He adds—"Until you are minister I must not permit myself to think of the honour of being known to you; when that happens, you will not find me a needy or a troublesome dependant." He further expresses the great desire he has to be honoured with Earl Temple's notice. Such is the substance of the three letters; they are by the same writer who afterwards used the signature of Junius, and they seem to prove that their author looked for patronage from Lord Temple, to whom he virtually offers his services as a political writer. Mr Smith supposes that hints and materials were forwarded to Lord Temple by his mysterious ally; and that from these, aided by his own knowledge of events and parties, his lordship wrote the letters signed Junius, Lady Temple acting as assistant and amanuensis. Exactly the reverse we take to have been the case. Lord Temple, and subsequently his brother, George Grenville (who became prime minister after the resignation of Lord Bute in 1762, and held office until dismissed to make way for the Rockingham administration in 1765), saw the importance of this brilliant and unscrupulous political writer, and supplied him with facts and scandal for his polished invectives and unmeasured vituperation. Lord Temple apparently had no talents as a writer, however active he may have been as a politician; and though Junius was of the Temple school, he assuredly was not Temple. (R. C. S.)

Gresham.

GRESHAM, Sir Thomas, the founder of the Royal Exchange and of the college called by his name in London, was born in 1519. His father had amassed great wealth and attained great eminence as a merchant and bill-broker in the reign of Henry VIII., and resolved to train his son to succeed him in his business. After a thorough education at Caius College, Cambridge, young Gresham was apprenticed to his uncle, a knight and a distinguished member of the Merchants Company. Under Edward VI. Gresham was employed on the same services as his father had performed for that king's father, and in the course of Edward's short reign he made no fewer than forty voyages to Antwerp on the royal business. By his financial skill and foresight he rendered great service to the revenues of the English crown, which he rescued from the extortions of Dutch and Jewish capitalists, and introduced with great effect the practice of raising money from native money-lenders, in preference to foreigners, who exacted a ruinous rate of interest. Mary and Elizabeth continued him in his employment, and the latter knighted him in 1559. He had now amassed an immense fortune, and built himself a splendid house in Bishopsgate Street (which, after his wife's death, was used as Gresham College, and the site of which is now occupied by the excise office), where he lived in great state, and where, by command of Elizabeth, he often entertained the ambassadors and visitors of rank that thronged her court. To these circumstances Gresham owed his title of the "Royal Merchant."

During his repeated visits to Antwerp, Gresham had seen and fully appreciated the value of a general place of rendezvous for the merchants of the city. Anxious to introduce something of the kind into London, he offered to build a suitable house if the citizens would furnish a site. A piece of ground was accordingly bought, and a building on the model of the Bourse of Antwerp was erected and ready for use in 1569. In the following year it was opened in state by Elizabeth, who, by a trumpet and herald, proclaimed it "The Royal Exchange." This building was burned down in the great fire of London, but was afterwards rebuilt on a larger scale and at a cost of nearly L.59,000. In 1838 this edifice was destroyed, like its predecessor, by fire; but on the same site a new exchange, of far greater dimensions and more splendid in style, was opened in 1844 by the Queen in state. See London.

Gresham invested a good deal of his wealth in landed property in various parts of England. At one of his estates, that of Osterlay near Brentford, he used sometimes to entertain Queen Elizabeth. Extant accounts describe the splendour and extravagance of these passages of her Majesty.

Gresham *College*. See London.

GRESSET, Jean Battiste Louis, the author of *Ver-Vert*, and many other poems, was one of the most original French writers of the eighteenth century. He was born at Amiens in 1709, and was educated there in the college of the Jesuits. In his seventeenth year he entered their order, and was sent to Paris to complete his studies at the Collège de Louis-le-Grand. He had not completed his twenty-third year when he wrote his inimitable little poem of *Ver-Vert*. There is not in the French language any badinage more pleasant or more graceful than the adventures of the famous parrot of Nevers. He next published the *Carême Impromptu* and the *Lutrin Vivant*, two brilliant trifles that display remarkable powers of narrative; and soon after, two charming epistles under the title of *La Chartreuse* and *Les Ombres*. Both of these epistles, but especially the first-named, are in their way as remarkable as the *Ver-Vert*. They are perhaps less correct; the copiousness of diction degenerates into luxuriance, and the *abandon* sometimes savours of carelessness. Yet the happy flow and pleasant cadences of the lines redeem the diffusion and the long sentences which have been often censured as the prevailing faults of almost all Gresset's compositions. An exception must be made in favour of his *Epître à ma sœur, sur ma convalescence*, which is in its way a perfect masterpiece, and far superior to many of the fugitive pieces of Voltaire in the same vein. Inferior in merit to these, yet still worthy of respectful mention, are the *Epître au père Bougeant*, *A ma muse*, *Epître d' un Chartreux*, &c. The fame of these works spread far and wide, and gained for their author the professorship of humanity at Tours. Here he had the misfortune to displease an influential and high-born religieuse, who accused him of doing mischief by the light and frivolous character of his poetry; and Gresset by way of punishment was transferred to La Flêche. To divert his thoughts, he set himself to translate the Eclogues of Virgil, which he accomplished, however, with very indifferent success. Finding his banishment intolerable, he applied for a recall; and when his superiors refused, he left the order. He always preserved a kindly remembrance of his connexion with it, however, as is evidenced by his *Adieu aux Jésuites*. He now removed to Paris, where he endeavoured to gain a reputation as a tragic writer. In 1740 he produced his drama of *Edouard III.*, which La Harpe pronounced a "roman sans vraisemblance, sans intérêt et sans aucune entente du théatre;" and his *Sidney*, played five years later, has no merits to save it from a like condemnation. Both were utter failures on the stage. Hardly more fortunate was his comedy of *Le Méchant*, which possesses very great merits, though these are more appreciable in the closet than on the stage. This comedy gives a most brilliant picture of the period which culminated in the Regency. Many of the lines are exquisitely finished, and many of them have become proverbs, but the plot is cold and commonplace. In 1748 Gresset obtained the much coveted honour of a seat in the French Academy; but a few years later he retired to his native town, where, with permission from the king, he founded an academy. The remainder of his life was spent in the neighbourhood of his beloved Amiens, which he never quitted unless business called him to the capital for a few days. One of these flying visits to Paris was made in 1774, to congratulate Louis XVI. on his accession, in the name of the French Academy. The new monarch ennobled him, and the dauphin (afterwards Louis XVIII.) made him historiographer of the order of St Lazarus. In his latter days Gresset became religiously disposed, and published a letter of regret for the mischief which he believed his comedies to have done. This retractation excited the wrath of Voltaire, who wrote of him in 1759—"Et ce polisson de Gresset qu' en dirons-nous? quel fat orgueilleux! quel plat fanatique!" This was at least ungrateful in the patriarch of Ferney; for Gresset had not only never joined in the outcry against him, but had even defended his *Zaïre* against its many assailants. Though it is hard to see what Gresset had to retract, or what evil influence he had exerted over French literature, he took great blame to himself for having multiplied editions of his works; and in deference to his religious advisers, he burned some unpublished plays, and two new cantos of *Ver-Vert*. Gresset died at Amiens, June 16, 1777.

Gresset, more than any other French poet, seems to have felt the influences of time and circumstance; and his works reflect to a surprising degree the influences by which he was surrounded at the time when each was written. He was the most original poet of his century in France, and neither belonged to any school nor followed any model. Not a trace of the Voltaireanism which was the ruling spirit of French literature in his day is to be found in his writings. His originality, refined humour, easy grace, and beautiful versification, will always secure for him an independent niche in the pantheon of French greatness. The best editions of his poems are those of Fayolle, Paris, 1803, 3 vols. 18mo; and Renouard, Paris, 1811, 3 vols. 8vo. The *Ver-Vert* has been twice translated into English, first by T. G. Cooper, and afterwards by Alexander Geddes; into German by J. M. Goetz; into Italian by L. A. Vincenzi; and into several other modern tongues.

GRETA, a river of England, in Cumberland. It rises in the mountain cove of Wythburn, and at the western base of Helvellyn enters the lake of Thirlmere or Leathes Water, through which it flows, and whence it emerges under the name of St John's Beck, flowing thence along the narrow but extremely picturesque valley of St John's, which is bounded on the W. by Naddle Fell, and on the E. by Great Dodd, a hill at the extremity of the Helvellyn chain. The lower end of the dale is closed by Saddleback, which rises on the N., with its deep ravines and rocky projections. This beautiful vale is the scene of Scott's poem of the *Bridal of Triermain*, and at its entrance from Thirlmere rise "the castled rocks," so graphically described by the poet. At the foot of Saddleback, which rears its summit above "the ruined towers of Threlkeld Hall," the stream is joined by the Glenderamaken, and takes thence the name of Greta. In its further course it receives the Glenderaterra, which comes bounding down between the mountains of Saddleback and Skiddaw. Thence the Greta passes under the woody side of Latrigg ("Skiddaw's Cub"), where its scenery is of the finest and most remarkable kind. Little more than a mile from the foot of Skiddaw stands the town of Keswick, on the left bank of this river, in the most beautiful vale. Quitting the town, the Greta falls into the Derwent at the foot of the noble lake of Derwentwater. The bed of the Greta is stony and rocky, but the channel immediately above Keswick has been to a great extent cleared of the immense stones which, by their concussion in high floods, produced the loud noises described in Wordsworth's sonnet on the Greta. Black's *Guide to the Lakes;* Works of Scott, Wordsworth, and Southey.

Greta, a romantic tributary of the Tees, in the N.W. part of the north-riding of Yorkshire. The valley of this stream was well known to the Roman conquerors; and in recent times its charms have been enhanced by the picturesque descriptions of Sir Walter Scott and other poets. The Greta rises by a few branches on the Stainmoor Forest and the northern slopes of Watercrag, the name first belonging to the branch that springs near Rere Cross on Stainmoor. These streams united flow past Bowes, a large village remarkable for its castle. Further down, the famous scenery which deservedly renders the Greta so remarkable, presents itself in the Cliff of Scargill and the woody and rocky banks of Brignall and Rokeby, so beautifully described in Sir Walter Scott's *Rokeby*. Quitting "Brignall's dark-wood glen," the river passes under Greta Bridge, and, flowing along the romantic ravine between Mortham Tower and Rokeby Park, it joins the Tees.

GRETA, "the rocky water," in the west riding of Yorkshire, and county of Lancaster, is a tributary of the Lune. It rises on the slope of the vast height of the Whernside, and flows along Chapeldale, a very remarkable valley bordered on one side by the towering elevation of Ingleborough, and on the other by the Ingleton Fells. In this secluded dale is Wethercoat Cave, one of the most astonishing natural curiosities in the kingdom—a waterfall of great depth and force, completely subterraneous, yet enlightened by the sun which sometimes forms a beautiful rainbow in the spray. The scenery at the village of Ingleton at the lower end of Chapeldale is truly magnificent, especially when viewed from the Burton Road. Here the roaring torrent is seen rushing through the deep chasm, the village church and tower rising far above on its brink, and Ingleborough rising immediately as from a base nearly to the distance of five miles. Here the Greta is joined by the stream of Kingsdale, a lonely glen between Ingleton Fells and the Ridge of Graygrath. In this moorland valley are the cavern of Yordas and the waterfall of Thornton Force. From Ingleton the Greta flows on to Black-Burton, and soon enters Lancashire, and terminates its rapid career in the broad channel of the Lune. Phillip's *Yorkshire*; Baines' *Lancashire*; and Lewis' *Rivers of England and Wales*.

GRETNA or GRAITNEY GREEN, a village of Scotland, county of Dumfries, 9 miles N.W. of Carlisle, and having a station on the Caledonian Railway. It has long been celebrated for its irregular marriages, noticed under BERWICKSHIRE.

GREVILLE, FULKE, Lord Brooke, an English poet of the brilliant Elizabethan period, was born in 1554, at Alcaster in Warwickshire. He was educated, along with his cousin Sir Philip Sydney, at Shrewsbury; and on leaving school, spent a considerable time at both the universities. After travelling on the Continent, and mastering some of the modern languages, he returned home; and through the influence of friends at court, obtained some honourable and lucrative employments, chiefly in connection with the government of Wales. In 1614 he was made under-treasurer and chancellor of the exchequer; and six years later, was raised to the peerage by the title of Lord Brooke of Beauchamp's Court. He was murdered in 1628, in a moment of rage, by an old servant of his own, who had no sooner done the deed than he threw himself upon the sword with which he had slain his master.

Fulke Greville's name is noteworthy in the history of English literature, both from his own contributions to it, and the services which he rendered to some of its needy cultivators in his day. Besides founding an historical lecture at Cambridge, he rendered much valuable aid to Davenant, Camden, Speed, and others, in their struggles with the hardships of a literary career. Of his own writings we may mention, *The Life of the Renowned Sir Philip Sidney*, Lond. 1652; *Certaine learned and elegant Workes of the Right Hon. Fulke Lord Brooke, written in his youth, and familiar exercise with Sir Philip Sidney*, Lond. 1633; *The Remains of Sir Fulke Greville, Lord Brooke, being Poems of Monarchy and Religion, never before printed*, Lond. 1670; *A Treatise of Human Learning; An Inquisition upon Fame and Honour; A Treatise of Wars*; &c. Greville's poems are remarkable for their depth of thought and masculine strength of expression. They abound, however, more in solemn ethical and philosophical thought than in poetic beauties, strictly so called; and the diction in which they are couched, though terse and powerful, is not unfrequently obscure. Southey calls Greville "the most difficult of all our poets," and adds, that "no writer of this or any other country appears to have reflected more deeply on momentous subjects." Charles Lamb, than whom few knew better the spirit of the Elizabethan era, says of Greville, that "he is nine parts Machiavel and Tacitus for one of Sophocles or Seneca. Whether we look into his plays or his most passionate love-poems, we shall find all frozen and made rigid with intellect."

The most noticeable feature of Lord Brooke's personal character was his friendship and admiration for his cousin Sir Philip Sidney. The inscription on his tomb-stone describes him as "The servant of Queen Elizabeth, the counsellor of King James, and the friend of Sir Philip Sydney."

GREW, NEHEMIAH, the earliest vegetable anatomist and physiologist of this country, was born at Coventry about 1628. He was educated as a Presbyterian; and on the change of the national form of religion, at the restoration of Charles II., he was sent to study at some foreign university, where he took his degree of doctor of physic. He settled first at Coventry, but removed afterwards to London, where he obtained considerable practice as a physician; and at length succeeded Mr Oldenburg in the office of secretary to the Royal Society. In this capacity, pursuant to an order of council, he drew up a catalogue of the natural and artificial rarities belonging to the society, under the title of *Musæum Regalis Societatis*, 1681. Besides several papers in the *Philosophical Transactions*, he also wrote—*The Comparative Anatomy of the Stomach and Guts*, fol.; *The Anatomy of Vegetables, of Roots, and of Trunks*, 1682, fol.; *Tractatus de Salis Cathartici Natura et Usu*; *Cosmologia Sacra*, or a *Discourse of the Universe, as it is the Creature and Kingdom of God*, fol. The works of Grew were translated into French and Latin; but, as it appears, by no means correctly, at least in the latter of these languages. He died suddenly, March 25, 1711. A genus of plants of the natural family of Tiliaceæ has been called "Grewia" in his honour.

GREY, EARL. The family from which Earl Grey sprung had been settled in Northumberland since the Conquest, and was at various times ennobled in its branches, giving birth to the Earls of Tankerville in Normandy and England, and the Barons Grey of Werk. Charles, first earl, son of Sir Henry Grey of Howick, was aide-de-camp to Prince Ferdinand at Minden, served long and well in the American War, and commanded the land forces at the reduction of Martinique, &c., in 1794. As the reward of his long service, he was created Baron Grey of Howick in 1801, and in 1806 Viscount Howick and Earl Grey. His eldest son Charles, the subject of this notice, was born at Falloden, near Alnwick, on the 13th of March 1764. He received his early education at Eton, and before he was sixteen entered King's College, Cambridge, where he studied with distinction for two years. He completed his education in the usual manner, by a continental tour, spending some time in France, Spain, and Italy. In 1786 he returned home, and soon after was sent to parliament by his native county. To the surprise of his friends, who belonged, of course, to the Tory party, the youthful member took his seat on the left of the speaker, and soon convinced the House that a formidable ally had been gained by the small but brilliant opposition that followed the banner of Fox. His maiden speech, Feb. 21, 1787, stamped his character as a speaker. The clearness and force of his argument, the animation and grace of his delivery, joined to a stately and aristocratic bearing, excited general admiration. The subject of debate was Mr Pitt's commercial treaty with France, which the young statesman followed his leader in opposing. A few years sufficed to show that he was capable of taking wider views, and shaping a course untrammelled by any docile subservience to a chief. He soon became a prominent man in the House; and to have commanded respect in a house where Fox, Burke, and Sheridan spoke on the same side with him, implied no common abilities. In the following year, though not yet twenty-four, he was appointed one of the managers in the trial of Warren Hastings.

From the very commencement of his political life, Mr Grey stood out as the champion of the principles which gave character to his whole career. The three words which summed up his ministerial programme in 1831, PEACE, RETRENCHMENT, and REFORM, constitute the main burden of his early parliamentary history. In the debates on the Regency Bill in 1789, indeed, he vigorously supported his party in defence of expenditure for one whom they "valued highly as an auxiliary." That Mr Grey's conduct, however, was guided by no servile partizanship was evinced by his subsequent resistance to the additional grant for liquidating the prince's debts. Of his principal appearances in the House from 1789 to 1792, it may suffice to notice his motion for inquiry into the convention with Spain in 1789, his opposition to a war with Russia (on the taking of Oczakow), and his efforts to mitigate the law of imprisonment for debt.

The outbreak of the French Revolution, and the rapid series of events from 1789 onwards, produced a schism in the camp of the Whigs. While Burke vehemently opposed the progress of the terrible phenomenon, and many of the Whigs consented to support the omnipotent minister, Fox and Grey, at the head of their small but resolute band, never swerved for a moment in their opposition to a war with France. Fearlessly committing himself to the advocacy of principles then regarded, not only by the order with which birth and feeling connected him, but by an immense majority of the people, as dangerous and revolutionary, Mr Grey became one of the chief promoters of a political confederacy, entitled "The Society of the Friends of the People." The very name smacked of revolution; and though most of the leading and more liberal Whigs joined this formidable association, Mr Fox declined to have anything to do with it, and even exerted himself privately against it. The avowed object was to obtain a reform in the system of parliamentary representation; and on the 30th April 1792 Mr Grey gave notice of a motion for next session, embodying the principle "that the evils which threaten the constitution can only be corrected by timely and temperate reform."

Before next session the aspect of parties had considerably altered. The general antipathy to everything known as "liberal"—a synonym to many minds for *Jacobinism*, *anarchy*, and *atheism*—had its due weight with timid and time-serving politicians, and a section of the Whigs were already meditating an alliance with the ministry. The demand for parliamentary reform was not indeed quite new. It had been for some time recognised as a valuable stock-cry for ambitious politicians, and so late as 1785 Mr Pitt himself spoke of it as "the great question which was nearest his heart." Mr Pitt had changed his sentiments, so persuasive was the French revolution; and it was no wonder that smaller men consented to leave things as they were. Of another stamp was Mr Grey. Amid almost universal selfishness and servility, he adhered to his principles from first to last, "unshaken, unseduced, unterrified." The faith of his youth continued to be the creed of his manhood, and its triumph was the glory of his old age.

On the 6th of May 1793, the House of Commons was inundated with petitions in favour of parliamentary reform. Among others, Colonel Macleod presented one from Edinburgh "of the whole length of the floor of the House." Last of all came Mr Grey with the petition of the People's Friends, a document "of such length as took nearly half an hour in the reading." It stated "with great precision and distinctness" the existing defects in the system of parliamentary representation, and the evils arising from the long duration of parliaments. It offered to prove that the treasury and the peers actually nominated 97 members, and influenced the return of 70 more, while 91 individual commoners procured the election of 139, in all 307—a majority of the entire House of Commons being thus returned by *one hundred and sixty individuals.* Mr Grey concluded his speech by moving for a select committee. After two long debates the motion was lost by 282 to 41. The House of Commons was well pleased with its own purity!

The war with France continued to meet with Mr Grey's determined opposition, even after it had come to be regarded by many of his party as a necessary evil. Acknowledging as he did (1794) that France "groaned under the most furious tyranny," and that "he would prefer the dominion of Nero or Caligula to the authority which now governed that nation," he made repeated motions (1795–96) for the opening of negotiations, dwelling always with great force on the ruinous expense of the war. The result was ever the same; "extended and animated speeches," able reasoning, and undeniable figures, were followed invariably by crushing minorities. The introduction of foreign troops into England, the suspension of the Habeas Corpus Act, the large addition to the grant for liquidating the debts of the Prince of Wales, and the "detestable" bill to restrain public meetings, were opposed with equal vigour and with as little success. His motions in 1796 (March 10 and May 6), on the state of the nation, and for an impeachment of ministers for malversation of public money, were lost in like manner by overwhelming majorities. His whole career was a desperate battle against invincible odds. On the 26th May 1797, he again brought forward a motion for parliamentary reform, and this time he put forth a plan. He proposed to leave the number of members unaltered, but to increase the county representation from 92 to 113; to extend the county franchise from freeholders to copyholders and leaseholders; the burgh franchise to all tax-paying householders; a voter only to vote for one member; the elections to be all on the same day; and, if the whole measure were carried, but not otherwise, triennial parliaments—a measure in principle little different from the Reform Bill of 1830. In concluding his speech, Mr Grey intimated that if his motion were lost he would despair of any further success in attempting to remedy the national ills, "and not again trouble the House with his observations." The motion was lost by 258 to 63, and the general question of parliamentary reform went to sleep for more than a generation. Mr Grey did not speak again in parliament till 1799, when he came forward in opposition to the Irish Union. For some years after this he made no public appearance of importance.

On the 23d of January 1806, Mr Pitt died, and the Whigs came into power under Grenville and Fox. Mr Grey, now Lord Howick, was made first lord of the admiralty. On the death of Mr Fox, a few months after his great rival, Lord Howick succeeded his departed chief as secretary for foreign affairs, and leader of the House of Commons. The time had now come for attempting with better hope some of the great reforms for which he had hitherto battled. One only of these the brief duration of his power permitted him to carry—the abolition of the slave trade. Early in March 1807, he moved the abolition of the oath which barred Roman Catholics and other dissenters from serving in the army and navy. The opposition shriek of horror at so latitudinarian a proposal, was more loud than edifying. The cries of "No Popery," "Church and King," &c., were raised with great effect from the expectant premier down to the orthodox street-sweeper. The old king took violent alarm, and demanded a written promise from his ministers not to meddle with the obnoxious topic. Mr Pitt had given him such a pledge, but Lord Howick and his colleagues respectfully declined to follow the example, and threw up their offices. A few years later their successors quietly passed the measure to the abjuration of which they owed their power.

On the dissolution of parliament, Lord Howick declining to contest the county of Northumberland, took his seat for Appleby. The death of his father in November of that year removed him to the House of Peers as Earl Grey, and for several years he enjoyed the calm pleasures of domestic retirement, steadily refusing the power which was more than once within his reach, while its acceptance involved the slightest compromise of the principles for the realization of which alone power had for him any charms. To the sweeter influences of family life, though outwardly a man of stiff and haughty reserve, he was keenly sensitive, and nowhere were these influences more attractively displayed than in the family circle at Howick. He had married in 1794 the only daughter of William, afterwards Lord Ponsonby, by whom he had ten sons and five daughters.

In 1809, 1810, and 1812, repeated overtures were made to Earl Grey and Lord Grenville to join the administration, but on each occasion the offers were unhesitatingly rejected. The Prince Regent was anxious to obtain the support of "some of those persons with whom the early habits of his public life were formed;" and after the last unsuccessful negotiation, on the death of Mr Perceval (May 1812), Lord Grey was careful to express his willingness that his friends should take office without him, promising his cordial support;—for himself untrammelled freedom was a stern necessity. During the eighteen succeeding years, Lord Grey headed the opposition in the House of Peers. In that time of depression and discontent which followed the peace, he opposed, consistently with his ancient policy, the harsh and coercive measures of the government, ever advocating, as the true and constitutional method of dealing with the existing evils, the removal of the causes from which they sprung. In no part of his public life did he earn higher honour than on the trial of Queen Caroline. His severe and dignified opposition to the Bill of Pains and Penalties had great weight in influencing the decision of the Peers, and alienated him for ever from a king who had been from the beginning unworthy of his friendship.

In 1827 Mr Canning became prime minister, and a shameful spectacle of place-hunting ensued. All the Whig leaders gave him their support. Earl Grey alone stood disdainfully aloof from a man whose tardy and doubtful liberalism contrasted so strongly with the unyielding consistency of his own political life. His utter distrust of Mr Canning's policy, and the severity with which he criticised his career, were sufficiently justified to his rigid sense of honour by that statesman's declaration of unqualified opposition to Reform and Roman Catholic Emancipation. In that session, in supporting the Duke of Wellington's unpopular amendment on the ministerial Corn Bill, he made the memorable declaration so characteristic of his severe patrician spirit. "If," said he, "there should come a contest between this house and a great portion of the people, my part is taken; and with that order to which I belong I will stand or fall." Coriolanus was not less "ambitious for poor knaves' caps and legs" than the lordly English reformer.

The time at last came for the triumphant realization of the great objects for which Earl Grey had so long and almost hopelessly contended. One of these—the relief of the Roman Catholics from civil disabilities—was granted by his opponents as a tardy concession to the imperious voice of the nation. In the debates on that question in the House of Lords, Earl Grey was said to have "excelled all others, and even himself." The long sleeping question of Reform was once more revived when disappointed politicians found that ministers were bidding for popular favour, and the exciting impulse of the French Revolution of 1830 gave new life to the agitation of grievances. The Iron Duke with fatal honesty scouted the necessity of change, and affirmed that the existing system of representation enjoyed "the full and entire confidence of the country." The country answered with a groan, and the Wellington ministry had to retire. The veteran leader of the Whigs was summoned to the helm of affairs; and on the 22d of November, Earl Grey, as prime minister, delivered his programme in the House of Peers. The history of the great event which crowned his long labours in the cause of Reform is elsewhere fully narrated (see BRITAIN). Throughout the whole of that trying and momentous time, the wisdom and firmness of the minister were manifested so conspicuously as to have earned him, in all impartial eyes, the glory of having guided the nation in safety over the kindling mine of revolution. The contest between his order and the people, of which he had once spoken, had actually arrived, and he sacrificed the independence of the peers to the will of the nation. That no other course was open to a man charged with so fearful a responsibility, is a sufficient answer to the charge of inconsistency. The moral courage requisite to so stern a duty was of higher account than a martyrdom purchased by civil war.

The acts of the first reformed parliament are already told (see BRITAIN). The emancipation of the slaves, the abolition of the East India Company's monopoly, the reform of the Irish Church, and of the poor-laws, were the chief of the legislative victories won under the rule of Earl Grey. His foreign policy, in the able hands of Lord Palmerston, was at once bold and pacific, temperate but just. Personal changes and differences finally shook the cabinet, and in November 1834 Earl Grey resigned. The remaining years of his life were spent in retirement. For some time he appeared occasionally in the House of Lords, frankly supporting the administration of Lord Melbourne. He died at his seat, in Northumberland, on the 17th July 1845, in the eighty-second year of his age. A political career so long useful and unblemished had seldom been exemplified. Faithful, in the midst of so much inconsistency and cowardice, to the principles for which he had braved obloquy in his youth, and resisted the fascinations of power, he attained at length, in the decline of life but not of vigour, the goal of all his strivings, the grand results, of which he had all but despaired. In the latter part of his political life he stood alone—an *ultimus Romanorum;* and, after his death, his characteristic part as a statesman was no longer possible to a successor, had any been fit to assume it. Let his defects have been ever so many, and they were few, the high example of his uncorrupted honour and constancy in the pursuit of great ends is a κτημα ες αει to the nation which reaps their fruits.

GREY, *Lady Jane*, a scion of the blood-royal of England, remarkable for her many virtues and accomplishments no less than her misfortunes, was born in 1537, at Broadgate, in Leicestershire. She was the great-granddaughter of Henry VII. of England. Mary, second daughter of that king, after being left a widow by Louis XII. of France, married Charles Brandon, Duke of Suffolk, by whom she had a daughter, who ultimately married Henry Grey, Marquis of Dorset. The offspring of this union was three daughters, the eldest of whom was Lady Jane Grey. From an early period she was distinguished for her talents; it is known for certain that while still very young she had thoroughly mastered Latin, Greek, French, and Italian, and was conversant with at least three of the Oriental tongues, Hebrew, Chaldee, and Arabic. In Ascham's *Schoolmaster* is given a touching account of the difficulties and hardships under which she pursued her studies, and the causelessly cruel treatment she experienced from her parents. In 1553, her father and the Duke of Northumberland, having risen to power after the downfall of Somerset, resolved to transfer into their own families the right of succession to the throne. A marriage was accordingly brought about between Lady Jane Grey and Lord Guilford Dudley, the Duke of Northumberland's fourth son; and the weakly Edward VI., when he found his end approaching, was easily persuaded to pass over his own sisters, Mary and Elizabeth, and nominate Lady Jane Grey and her husband as his successors to the English throne. Some days elapsed after the king's death before Lady Jane was told that she was queen of England; and when she came to know the fact, she could only with the greatest difficulty be persuaded to avail herself of it. After a reign of ten days, she quietly resigned the throne in favour of Mary. Her husband and she were thrown into the Tower; and though it was not originally intended to put them to death, yet, in consequence of Wyat's insurrection, they were executed together, Feb. 12, 1554. Lady Jane displayed on the scaffold the same pious resignation and calm self-possession that had distinguished her throughout life. (Ascham's *Schoolmaster*; *Biog. Brit.*; Burnet's *Hist. Ref.*)

GREYHOUND. See Hound, and Mammalia.

GREYWACKE, or Grauwacke, a rock formation, composed of quartz, flinty slate, clay slate, and felspar, in pieces varying in size, and cemented together by a clay-slate basis. See Mineralogy.

GRIESBACH, Johann Jacob, an eminent German biblical critic, was born at Butzbach, in Hesse-Darmstadt, Jan. 4, 1745. He was educated at Frankfort-on-the-Maine, and completed his studies at the universities of Tübingen, Halle, and Leipzig. He distinguished himself especially in all theological and biblical inquiries, and was the favourite pupil both of Semler and Ernesti. At the early age of twenty-four he had determined to devote himself to the scientific study of the doctrines and text of the New Testament. To carry out his plan, he began a literary tour through Germany, Holland, and England, making friends for himself among the leading literati of all these countries, and amassing large stores of valuable materials for his great work. In 1770 he returned to Frankfort to arrange and digest these; but in the following year was made theological lecturer, and in 1773, extraordinary professor of theology at Halle. In this office he distinguished himself so much that he was offered a professorship at Jena, which he accepted. In 1780 he became rector of the university, and was promoted to various other responsible offices. The Duke of Saxe-Weimar nominated him his ecclesiastical councillor, and a member of his states; and he had been already made prelate and deputy of the district of Weimar. About ten years before this, he had married a sister of the famous Schütz, with whom he seems to have lived happily till his death, March 24, 1812. Griesbach's first edition of his text of the New Testament was published at Halle in 1774, in the form of a hand-book for the students then attending his lectures. The first volume of the second edition was published in 1796, and the second in 1807. A font of types was cast expressly for this edition by the famous type-founder Göschen; and as the expense of the paper was borne by the Duke of Grafton, chancellor of the university of Cambridge, the grateful author published his book simultaneously in London and Halle. The book has been since twice reprinted in London, once in 1809, and again in 1818.

Griesbach's recension of the text of the New Testament is based on a comparison of the three great classes into which he divides the various Greek MSS. These sets of MSS. are the Alexandrine, the Western, and the Byzantine or Asiatic, which latter is the basis of the Greek Vulgate. Of these, the first is by far the best, as Griesbach considers undeniable, from the coincidence between the Scripture quotations in the extant works of Origen and the text of the celebrated Alexandrian MS. of the New Testament. The Byzantine, in opposition to Matthiæ and Scholz, he considers far from reliable. But his whole system has been attacked repeatedly in Germany and England, in the latter country more especially by Dr Nolan in his *Enquiry into the integrity of the Greek Vulgate, or received Text of the New Testament*, and by Archbishop Lawrence in his *Remarks upon the Systematical Classification of MSS. adopted by Dr Griesbach.*

Griesbach's chief works, in addition to those already mentioned, are—*Dissertatio de fide historicâ, ex ipsâ rerum quæ narrantur, natura judicandâ*, 4to, 1764; *Diss. hist. theol. locos theologicos ex Leone M. Pontifice Romano Sistens*, Halle, 4to, 1768; *Dissertatio de Codicibus quatuor Evangeliorum Origenianis*, 4to, 1771; *Dissertatio curarum in historiam textûs Græci Epistolarum Paulinarum specimen*, Jena, 1777; *Programma de fontibus unde Evangelistæ suas de resurrectione Domini narrationes hauserint*, 1784; *Progr. de imaginibus Judaicis quibus auctor Epistolæ ad Hebræos in describenda Messiæ provincia usus est*, 1791–92; *Symbolæ criticæ ad supplendas et corrigendas varias N. T. lectiones; Accedit multorum N. T. codicum Græcorum descriptio et examen*, Halle, 1785–93; *Commentar. critic. in textum Græcum N. T.*; Griesbach's *Opuscula Academica* were published at Jena in 1824.

GRIFFIN, or Gryphon (*gryphus*, *γρύψ*), in the natural history of the ancients, the name of an imaginary bird of prey, of the eagle species, represented with four legs, wings, and a beak; the upper part resembling an eagle, and the lower a lion. This animal, which was supposed to watch over gold mines and hidden treasures, was consecrated to the sun; and the ancient painters represented the chariot of the sun as drawn by griffins. According to Spanheim, those of Jupiter and Nemesis were similarly provided. The griffin of Scripture is that species of the eagle called in Latin *ossifraga*, or osprey. The griffin is frequently seen on ancient medals, and is still borne in escutcheons. Guillim blazons it rampant, alleging that any very fierce animal may be so blazoned as well as the lion; but Sylvester, Morgan, and others use the term *segreiant* instead of rampant. The griffin was also an architectural ornament among the Greeks, and was copied from them, with other architectural embellishments, by the Romans.

GRIMALDI, one of the four ancient families of "high nobility" of Genoa. The lordship of Monaco, afterwards elevated to the rank of a principality, belonged to the Grimaldi from A.D. 980 for more than 600 years. With the Fieschi they always acted an important part in the history of Genoa, especially in the disputes between the Ghibelines and the Guelphs, to which latter family both parties belonged. The influence of the Grimaldi was much increased by their large estates in France and Italy. Of this family there were several eminent men, of whom the principal are: 1. Ranieri Grimaldi, the first Genoese who conducted the naval forces of the republic beyond the straits of Gibraltar. He sailed to Zealand, in the service of Philip (the Fair) of France, in 1304, with sixteen Genoese galleys and twenty French ships under his command; and there he defeated and made prisoner the Count Guy of Flanders, who commanded the enemy's fleet of eighty sail.—2. Antonio Grimaldi, likewise was distinguished in the naval service of his country in the early part of the fourteenth century. His victories over the Catalonians and Aragonese, who had committed aggressions on the Genoese, gave the latter a decided maritime ascendency for a long time; but at length, in 1353, the Catalonians, assisted by the Venetians, under the command of Nicholas Pisani, gave him battle, and nearly destroyed his whole fleet.—3. Giovanni Grimaldi is celebrated for the victory he gained over the Venetian admiral Trevesani, on the Po, in 1431, when, in sight of Carmagnola's army, he succeeded in taking twenty-eight galleys and a great number of transports, with immense spoils.—4. Domenico Grimaldi, cardinal, archbishop, and vice-legate of Avignon, was famous as a naval commander, and eminent as a zealous extirpator of heresy from the Romish Church. Though a bishop at the time, he distinguished himself by his skill and courage at the battle of Lepanto in 1571.—5. Geronimo Grimaldi, born in 1597, was sent by Urban VIII. as nuncio to Germany and France, and the services he rendered the Roman hierarchy were rewarded by a cardinal's hat in 1643. His whole career was highly honourable. He was bishop of Aix, and strenuously endeavoured to reform the manners of the clergy in the diocese by establishing an ecclesiastical seminary. He also founded an hospital for the poor, and annually distributed 100,000 livres in alms alone. He died at the advanced age of eighty-nine, in the year 1685.

GRIMM, Friedrich Melchior, Baron, born at Ratisbon in 1723, is a remarkable instance of the power of letters in the eighteenth century. He was born of poor parents, who, however, gave him an education far beyond their station. On completing his studies, he tried his fortune as a dramatic writer, and, failing utterly, went to Paris as tutor to the young Count Schönberg, whose father was Polish minister at the court of Versailles. He there became reader to the Prince of Saxe-Gotha, and attached himself to the Encyclopedists, who then numbered in their ranks nearly all the intellect of Paris. In the contest as to the respective merits of French and Italian music, which at this time divided the French capital, Grimm sided with the partizans of the latter, and published on the subject a very witty little pamphlet, entitled *Le petit Prophète de Böhmischbroda*, which covered the champions of the national music with ridicule, while Rousseau drove them out of the field altogether by his *Lettre sur la Musique Française.* Their common fondness for music was the origin of a sincere friendship between Grimm and Rousseau. Grimm's reputation as a man of wit and talent now threw open to him the best *salons* in Paris. His inimitable social tact, his fine conversational powers, and the perfect elegance of his manners and person (on which last he bestowed infinite pains), all strengthened the impression which he had made on his first appearance as an author. His success was still further ensured by his powers of fascinating the fair sex, with several of whom simultaneously he contrived to pass as the perfect model of a passionate and disinterested lover. After the death of the Comte de Friesen (nephew of Marshal Saxe), to whom Grimm owed much, and whose secretary he had been, he attached himself to the Duke of Orleans, and began writing, for the benefit of some of the German princes, those literary bulletins, in which, with great ability, he analyzed the current literature of France. In 1776 he became the Duke of Saxe-Gotha's minister at the French court. When the Revolution broke out he retired to Gotha. In 1795, Catherine II. of Russia appointed him her minister at Hamburg, and her successor Paul confirmed him in this office. A sudden illness deprived him of the sight of an eye, and he once more returned to Gotha, where he died in 1807, at the advanced age of eighty-four.

Grimm's only title to remembrance by posterity is his *Correspondence Litteraire, Critique et Philosophique*, of which there have been several editions, the best being that in 15 vols., Paris, 1829. This work is an invaluable guide to all who desire to know the secret, literary, and social, and even political history of France during the middle and towards the close of the eighteenth century. But it must be remembered that its author was till his death—what he had been all his days—an adventurer, without fixed principles, a professed atheist, and, on the score of *morale*, infinitely inferior to the Diderots and D'Alemberts, who respected, and even feared him. Of these men Rousseau alone seems to have thoroughly understood the intense selfishness, egotism, and spirit of intrigue that constituted the real basis of Grimm's character. To the latter quality he owed mainly his success in life; and that he possessed it in no common degree may be easily imagined from the skill with which he finally worked his way to the top of the social ladder.

GRIMMA, a town of Saxony, circle of Leipzig, on the Mulde, 16 miles S.E. of Leipzig. In the middle ages Grimma was an important commercial town. It has a bridge over the river; an old castle; manufactures of cotton, linen, and woollen stuffs; mathematical, surgical, and musical instruments; and some trade. Pop. (1849) 5384.

GRIMSBY, Great, a municipal and parliamentary borough and seaport-town of England, county of Lincoln, on the S. side of the estuary of the Humber, near its mouth, and 15 miles S.E. of Hull. In the reign of Edward III. it was a port of such importance as to furnish that monarch with 11 ships and 170 mariners for the siege of Calais; but the gradual blocking up of the harbour by the accumulation of mud and sand led to the decay of the port, until the construction of the new harbour in the beginning of the present century. This soon became inadequate for the increasing commerce; and, in 1846, a new harbour was commenced, and the foundation-stone was laid by Prince Albert 17th April 1849. The new works occupy a space of 135 acres, gained from the sea, and comprise a wet dock of upwards of 20 acres, with two entrance-locks, having in front a tidal basin of 13 acres. The latter is formed by two timber piers, which are together about 2000 feet in length, and is provided with landing-slips. The chambers of the two entrance-locks connecting the tidal basin and the dock are respectively 45 feet in width by 200 in length, and 70 in width by 300 in length. At the dock entrances the average depth of water is about 9 feet at ebb and 26 feet at high tides, the latter being the permanent depth in the dock itself. There are extensive warehouses and sheds for the storing of merchandise, and lines of railway extend along each side of the dock. The dock was opened on 23d March 1852. The Manchester, Sheffield, and Lincolnshire, and the East Lincolnshire lines of railway terminate here. The vessels registered as belonging to the port on 31st December 1853 were,—under 50 tons, 74 sailing-vessels, tonnage 2151, and 4 steamers, tonnage 71; above 50 tons, 14 sailing-vessels, tonnage 1251, and 2 steamers, tonnage 1030. The vessels that entered and cleared at the port during that year were,—Coasting trade, sailing-vessels, inwards 251, tonnage 17,143; outwards 176, tonnage 14,656; steamers, inwards 4, tonnage 1563; outwards 1, tonnage 346;—Colonial and foreign trade,—sailing-vessels, inwards 420, tonnage 82,397, outwards 243, tonnage 51,039; steam-vessels, inwards 88, tonnage 33,760, outwards 95, tonnage 36,311. The amount of customs duty received at the port during 1852 was L.29,101. The parish church of Grimsby is a large cruciform structure, with a tower and steeple rising from the centre. There are a free grammar and other schools, a mechanics' institute, &c. Grimsby is governed by a mayor, four aldermen, and twelve councillors, and returns one member to parliament. Pop. (1851) of parliamentary borough, 12,263; of municipal do., 8860.

GRINDELWALD, a village of Switzerland, in one of the most picturesque valleys of the Canton of Berne. It is 3250 feet above the sea, and is surrounded by the lofty Wetterhorn, Schreckhorn, and Grindelwald Mountains. Near it are the two glaciers of Upper and Lower Grindelwald.

GRINDSTONE, a mass of sandstone cut into a flat circular form, and mounted on a spindle, which is commonly made to revolve by means of a winch. It is used for grinding metal or sharpening tools. The finer grindstones, such as those called polishing stones by the cutlers, are obtained from different rocks in Derbyshire, Staffordshire, and Warwickshire. Stones of the common kind are exported from Newcastle.

GRINSTEAD, East, a market-town of England, county of Sussex, 28 miles S. of London. It is pleasantly situated on an eminence, and the tower of its parish church forms a conspicuous object for a great distance around. The church and town-hall are both handsome edifices. At the east end of the town is Sackville College, a quadrangular stone building, erected in 1616. It was founded by Robert, Earl of Dorset, for the support of twenty-four aged unmarried persons of both sexes, but in consequence of a deficiency of income the number has been reduced to twelve. Each of these has a comfortable room, and L.8 a-year in money. Market-day Thursday. Previous to the Reform Act, by which it was disfranchised, E. Grinstead returned two members to parliament. Pop. of parish (1851) 3820.

GRISONS (Ger. *Graubünden*), the largest and most eastern of the cantons of Switzerland, is bounded on the N.E., E., and S.E., by Liechtenstein and the Austrian dominions, and on the other sides by the cantons of St Gall, Glarus, Uri, and Ticino. It lies between N. Lat. 46. 15. and 47. 4., and E. Long. 8. 40. and 10. 29.; is 80 miles in length from E.N.E. to W.S.W., and 45 in breadth, and has an area of 2963 square miles. Lofty ranges of mountains constitute its boundaries on almost every point, and occupy a great part of the interior; indeed, the whole canton may be said to be mountainous. The main chain of the Rhaetian Alps crosses the canton from W. to E., at first separating it from Ticino and Italy, and afterwards dividing the waters of the Rhine from those that flow into the Inn. A great portion of this chain is above the limit of perpetual snow; and some of the summits, as those of the Muschelhorn, the Piz Val Rhin, and Monte Maloya, considerably exceed the height of 10,000 feet above the sea. It is crossed by the passes of the Splügen, Bernardin, Albula, and Scaletta. Another mountain range, an offset of the Lepontine Alps, and little inferior in height to the former, extends in a N.E. direction from the St Gothard, and forms the western boundary of the canton, dividing the waters of the Rhine from those of the Reuss and Linth. A third chain bounds the Engadine on the S.E., and a fourth, called the Rhaetihon, forms the boundary between the Grisons and the Vorarlberg. The valleys are numerous and strikingly beautiful. There are five greater valleys, known as the Hither Rhine, the Farther Rhine, the Engadine, the Albula, and the Brettegau; and nearly 150 smaller valleys are connected with these. There are no fewer than 240 glaciers and 56 waterfalls within the canton. The Rhine and the Inn both have their sources in the Grisons, as have also several tributaries of the Upper Adige, the Po, and the Adda. The scenery is peculiarly grand and magnificent. The character of the country unfits it for agriculture, and consequently its chief wealth consists in cattle, which, with timber, constitute its principal exports. Sheep, goats, and hogs are also numerous. Iron, lead, and zinc are among the mineral products, but few mines are worked. The manufactures are not important, and are chiefly for domestic use. The climate is very various. In the upper valleys the snow lies for seven months in the year, while in some of the others the temperature is sufficiently mild to admit of the cultivation of the vine. The corn produced does not by half supply the wants of the inhabitants. Hemp and flax are largely cultivated. The principal branch of commerce is the transit trade with Italy, across the Alps. The old division of the canton into three leagues is still adhered to; the Gray League (*Graue Bund*), the League of God's House (*Gottes-haus Bund*), and the League of Ten Jurisdictions (*Zehngerichte Bund*). Each of these comprise several jurisdictions (in all twenty-six), and these in their turn contain a number of communes, which may almost be said to be so many little republics, as each exercises within itself rights almost independent. The legislative power is vested in the great council, as also the election to public offices, and the settling of disputes among the communes; but the people have a *veto* in the passing of new laws, and in the concluding of treaties. It is composed of sixty-five members chosen annually, in the different jurisdictions, by universal suffrage of the male population above seventeen years of age. It nominates a commission of nine members, charged with the preparation and preliminary discussion of subjects coming before it; and also a small council of three members, one for each league, intrusted with the executive. Pop. (1850) 89,895, of whom 38,039 were Roman Catholics, and 51,855 Protestants. About 50,000 speak Romansch, 30,000 German, and 9000 Italian.

GRIT, or GRITSTONE, a name given to several kinds of sandstone used in building, as well as for millstones or grindstones, and sometimes for filtrating water. In geology the term is applied chiefly to the *calcareous grit*, a part of the middle oolite formation; and to the *millstone grit*, a rock which contains embedded quartz pebbles.

GROAT, an old English silver coin, equal to fourpence. Other nations, as the Dutch, Poles, Saxons, Bohemians, and French, have likewise their groats, groots, groschen, gros, and the like. In England in the Saxon times, no silver coin larger than a penny was struck, nor after the Conquest till the reign of Edward III., who about the year 1351 coined grosses or great pieces, which went for fourpence each; and so the matter stood till the reign of Henry VIII., who in 1504 first coined shillings.

GROATS, oats deprived of the husks.

GROCYN, WILLIAM, a distinguished classical scholar, was born at Bristol in 1442, and educated at Winchester School, and New College, Oxford. He was the friend of Dean Colet the tutor of Erasmus, and the godfather of Lilly the grammarian. A Latin epistle of his to Aldus Manutius is prefixed to Linacre's translation of *Proclus de Sphæra.* It was Grocyn who first publicly taught Greek in Exeter College, Oxford, and introduced a better pronunciation of that language than had hitherto been known in England. By the introduction of this language alarming many as a most dangerous innovation, the university divided itself into two factions, distinguished as "Greeks and Trojans," who bore such decided hostility to each other that they proceeded to open hostilities. Thus was Grocyn situated when Erasmus came to Oxford and studied Greek under his tuition. After distinguishing himself as one of the most learned and able men of his day, Grocyn died at Maidstone in 1519. His will is printed in the appendix to Knight's *Life of Erasmus.*

GRODNO, a government in the middle and western portion of European Russia, lying between N. Lat. 51. 30. and 54. 20., E. Long. 23. 7. and 26. 42., and bounded on the N. by the government of Vilna, E. by Minsk, S. by Volhynia, and W. by the kingdom of Poland. Its greatest length is about 173 miles and its greatest breadth about 120. Area 14,700 square miles. The surface is an extended sandy plain, broken only by a few chalk hills. A large portion of it is covered with forests, particularly in the N., while in the S. are extensive marshes. The principal rivers are the Niemen, Bug, Narew, and Priepec. The climate is moist and foggy. Rye is the principal grain cultivated, of which about 2,348,000 English quarters are produced annually, and about one-third of this quantity is exported. Few other kinds of grain or vegetables are grown for food; but considerable quantities of flax, hemp, and hops are raised. The pasture lands are extensive, and the rearing of cattle obtains a considerable amount of attention. The sheep have been much improved by crossing, and wool constitutes a principal article of export. The mineral products comprise iron, chalk, nitre, and building stone. The manufactures are inconsiderable, and chiefly for domestic use; the principal are woollen cloths and leather. In the N. the inhabitants are mostly Lithuanians, elsewhere the Rusniaks prevail. It is divided into eight circles. The principal towns are Grodno, Novogrodek, Slonim, and Brzesc-Litovski. Pop. (1849) 905,666.

GRODNO, the capital of the foregoing government, is situated at the foot of a hill on the right bank of the Niemen, 90 miles S.S.W. of Vilna. The town is irregularly built on a large uninclosed space, and the houses are mostly of wood. The streets, with the exception of two or three, are unpaved and extremely dirty. It has a spacious and handsome modern palace, built by Augustus III. of Poland, and a more ancient one now uninhabitable. There are nine Roman Catholic churches, two Greek churches, a Lutheran church, and two synagogues; also a gymnasium, a riding school, and an academy of medicine, founded by Stanislaus Augustus, in connection with which are a library, museum of natural history, and a botanic garden. The manufactures are inconsiderable. Pop. (1849) 16,527.

GROIN, that part of the abdomen next the thigh.

Groin, in *Architecture*, the angular curve formed by the intersection of simple vaults crossing each other at any angle, and leading to a common centre or apex. See plates to Architecture.

GRÖNINGEN, a province of Holland, forming the N.E. extremity of that kingdom, and bounded on the N. by the German Ocean, E. by the estuary of the Ems, the Dollart, and Hanover, S. by the province of Dantzig, and W. by that of Friesland. Its greatest length from S.E. to N.W. is 50 miles, and its extreme breadth in the northern part 34 miles. Area, 883 square miles. The surface is level and everywhere intersected by canals and ditches, whilst it is protected by continuous dykes against the inundations of the sea. The soil is generally heavy and marshy; and in several parts, especially in the S.E., are extensive swamps. The principal rivers are the Hunse and the Aa. The climate is humid and unhealthy. Along the shore there extends a tract of land from 18 to 20 miles in breadth, which, by being well drained and embanked, bears excellent crops of oats and some barley. The land farther from the shore is generally sandy heath, affording much turf, and yielding with care a supply of potatoes. The pastures constitute the chief wealth of this province, and support a great number of excellent cattle. The butter and cheese are, however, inferior to those of the provinces of Holland and Friesland. The manufactures are few and insignificant. The only town of importance is the capital. The province is divided into three arrondissements—Gröningen, Winschoten, and Appingadam. Pop. (1854) 199,563.

Gröningen, the capital of the above province, and the most important town in the northern part of Holland, is situated on the Hunse, 92 miles N.E. of Amsterdam. It is neat, clean, and regularly built, and is surrounded by walls and ditches. It has twelve churches, the finest of which is St Martin's, a handsome Gothic edifice, surmounted by a lofty spire. The town-hall is an elegant modern structure, in the Bree-market, one of the grandest squares in the kingdom. The university, founded in 1614, has an excellent museum of natural history and a botanic garden, and is attended by about 400 students. Gröningen has an academy of painting, sculpture, and architecture; schools for the blind and the deaf and dumb; societies of natural history, chemistry, and literature; a public library, &c. It has an active trade in cheese, butter, cattle, corn, and other agricultural products; and ship-building is carried on. There are paper-mills, and some factories of woollen and silk stuffs, but, generally speaking, the manufactures are inconsiderable. Pop. (1850) 33,695.

GRONOVIUS, the Latinized form of Gronov, Johann Friedrich, a learned scholar and critic, was born at Hamburg on the 10th of September 1611. He went through his early studies with great distinction at Bremen, after which he studied law at Altdorf under the learned professors who had conferred celebrity on that school. To extend his knowledge by travel, and to converse with the learned and explore the libraries, he visited the principal cities of Holland, England, and France. In 1658 he succeeded Daniel Heinsius, the celebrated professor of belles-lettres in the university of Leyden; and in that city he died on the 28th of December 1671. Gronovius was a man of equal learning and modesty; and, as he was naturally disinclined to controversy, he avoided those literary disputes by which so many then sought to obtain distinction. For a correct list of his numerous works, we refer to the *Biblioth. Erudit. Præcoc.* of Klefeker, and to the *Dictionnaire* of Chauffepié, and shall only mention the following:—

Diatribe in Statii poetæ Sylvas, Hague, 1637, in 8vo; *De Sesterciis sive subsesivorum Pecuniæ veteris Græcæ et Romanæ libri iv.*, Deventer, 1643, in 4to; *Observationum libri iv.*, Deventer, 1662, in 12mo; *Laudatio funebris Joannis Golii*, Leyden, 1668, in 8vo; *De Musæo Alexandrino Exercitationes Academicæ*, inserted in the eighth volume of the *Thesaurus Antiquitatum Græcarum*; *Lectiones Plautinæ, quibus non tantum fabulæ Plautinæ et Terentianæ, verum etiam Cæsar, Cicero, Livius illustrantur*, Amsterdam, 1740, in 8vo; *Notes on the Treatise of Grotius De Jure Belli et Pacis.* Gronovius also revised the text, and published editions with notes, of Titus Livius, Statius, Pliny the Elder, Justin, Tacitus, the Senecas, Aulus Gellius, Phædrus, and Paulinus, almost all of which form part of the *Variorum* collection.

(J. B—E.)

Gronovius, *Jacobus*, son of the preceding, and one of the most laborious philologers of the seventeenth century, was born at Deventer (Holland) on the 20th of October 1645. At an early age he had read all the masterpieces of antiquity. In the course of his travels he visited England, where he occupied himself several months in collating the manuscripts in the libraries of Oxford and Cambridge. He then returned to Leyden, and there published, in the year 1670, an edition of Polybius, with notes, amongst which he inserted those that Casaubon had on his deathbed bequeathed to him. This first editorial effort did him much honour, and well merited the offer, which was in consequence made him, of a chair in the academy of Deventer. But entertaining the intention of continuing his travels, he declined the proffered situation, and almost immediately set out for Paris, where he met with a most distinguished reception. The death of his father obliged him to return a second time to Leyden; but as soon as he had arranged his affairs, he again set out along with M. Paats, ambassador of the States-general, to Spain; and having travelled through that country, he embarked for Italy. The Grand Duke of Tuscany retained him in his states by appointing him professor in the university of Pisa; and Gronovius profited by the facility he had of visiting Florence, to form a connection with Magliabecchi, who placed at his disposal all the treasures of the Medicean library. At the end of two years he prevailed on the grand duke to accept his resignation; visited Venice and Padua; and traversed Germany on his way to Deventer, where it was his intention to settle. But scarcely had he arrived in that city when the curators of the university of Leyden tendered him a chair, and pressed their offer so urgently that he was induced to accept it; and he taught at Leyden till his death in 1716. If he inherited the erudition of his father, he had neither his gentleness nor his moderation. Never was there a man fonder of disputation, or more unjust towards the adversaries whom, for the most part, he raised up against himself by his asperity and haughtiness. It would be tedious, if not disgusting, to enter into details respecting the quarrels he had to maintain with Fabretti on the sense of some passages in Livy; with Feller and Perizonius as to the manner of Judas's death; with Vossius on Pomponius Mela; with Bentley and John Leclerc on the corrections of Menander; with Kuster on Suidas, &c. The scurrility he indulged in these discussions, which did not always terminate to his advantage, and his exorbitant vanity, caused him to be compared to Scioppius, and procured for him the unenviable distinction of a place in the work of Mencken on the Empiricism of the Learned. In the *Memoirs of Nicéron* will be found a notice of his life, followed by a catalogue of his works, forty-six in number.

The most celebrated, as well as the most important of these, is the *Thesaurus Antiquitatum Græcarum*, Leyden, 1697 and the following years, in 13 vols. folio. For this invaluable collection he adopted the plan traced out by Grævius in the *Thesaurus Antiquitatum Romanarum*, Utrecht, 1694, in 12 vols. folio. Gronovius published new editions of several authors commented on by his father, such as Seneca, Aulus Gellius, Phædrus, and others; and he also edited Macrobius, Polybius, Tacitus, Pomponius Mela, Cicero, Ammianus Marcellinus, Quintus Curtius, Suetonius, Arrian, Minutius Felix, Herodotus, Cebes, and some ancient geographers; the poem of Manetho on the stars; the *Dactylotheca* of Gorlæus; the *Lexicon* of Harpocration, &c., the greater part of which, enriched with correction and notes, form part of the *Variorum* collection, though, in general, not held in much estimation. The other productions of Gronovius consist of Theses, Discourses, and Diatribes, of which a list will be found in the *Memoirs of Nicéron*, and also in the *Biblioth. Erudit. Præcocium* of Klefeker. (J. B—E.)

GROOM (Flemish, *grom*, a boy), a servant; more particularly one who takes care of horses in the stable, &c.

Groom is also the title of several superior officers of the royal household; as groom of the chamber, groom of the stole or robes, &c. See Household, *Royal*.

GROOTE Eylandt (*Great Island*), the largest island in the Gulf of Carpentaria, North Australia; in S. Lat. 14., E. Long. 136. 40. It is of an irregular form, and is 45 miles in length from N. to S., with an average breadth of 30 miles. It is generally barren and unproductive on the coast; but towards the interior is covered with wood.

GROSE, Francis, a celebrated English antiquary, was of Swiss extraction, but born at Greenford in Middlesex, about the year 1730 or 1731. The bias of his mind showed itself early; and his father indulging it, procured him the office of Richmond Herald in the Herald's College. In 1763 he exchanged this position for that of adjutant and paymaster of the Hampshire militia, where, as he himself humorously observed, the only account-books he kept were his right and left pockets, into the one of which he received, and from the other of which he paid. This carelessness exposed him to serious losses; and after a vain attempt to repair them by accepting a captaincy in the Surrey militia, he began to turn to account his excellent education and his powers as a draughtsman. In 1773–76 he published his *Views of Antiquities in England and Wales*, a work which brought him money as well as fame. In the following year he added two more volumes to this work; and in 1789 he set out on an antiquarian tour through Scotland. In the course of this journey he visited Burns, who composed in his honour the famous song beginning "Ken ye aught o' Captain Grose," and that other, still more famous, "Hear, land o' cakes and brither Scots." In 1790 he began to publish the results of what Burns called "his peregrinations through Scotland;" but he had not finished the work when he bethought himself of going over to Ireland and doing for that country what he had already done for Great Britain. Shortly after his arrival in Dublin, however, he was seized at table with an apopletic fit, and died in a moment.

Grose was a sort of antiquarian Falstaff; at least he possessed in a striking degree the knight's physical peculiarities; but he was a man of true honour, a valuable friend, and an inimitable boon-companion. Though his professional merits were far from contemptible, he showed to greatest advantage as a social being; his humour, his varied knowledge, and his good nature, were all eminently calculated to make him a favourite in society. As Burns says of him—

> "But wad ye see him in his glee,
> For meikle glee and fun has he,
> Then set him down, and twa or three
> Guid fellows wi' him,
> And port, O port! shine thou a wee,
> And then ye'll see him."

Subjoined is a list of Grose's works:—

The Antiquities of England and Wales, in 8 vols. 4to and 8vo; *The Antiquities of Scotland*, in 2 vols. 4to and 8vo; *The Antiquities of Ireland*, in 2 vols. 4to and 8vo, a posthumous work edited by Mr Ledwich, 1794; *A Treatise on Ancient Armour and Weapons*, 1785, in 4to; *A Classical Dictionary of the Vulgar Tongue*, 1785, in 8vo; *Military Antiquities, being a History of the English Army from the Conquest to the Present Time*, 1786, 1788, in 2 vols. 4to; *The History of Dover Castle*, by the Rev. William Darell, 1786, in 4to; *A Provincial Glossary, with a Collection of Local Proverbs and Popular Superstitions*, 1788, in 8vo; *Rules for Drawing Caricatures*, 1788, in 8vo; *Supplement to the Treatise on Ancient Armour and Weapons*, 1789, in 4to; *A Guide to Health, Beauty, Honour, and Riches, being a collection of humorous advertisements, pointing out the means to obtain these blessings*, with a suitable introductory preface, 8vo; *The Olio*, a collection of essays, jests, and small pieces of poetry, highly characteristic of Grose, though certainly not all by him, 1793, in 8vo.

GROSS, the number of twelve dozen.

Gross Weight, in commerce, the weight of merchandise and goods with the dust and dross, as also of the bag, cask, chest, &c., in which they are contained; and out of this gross weight allowance is to be made for tare and tret.

Gross, or *Grossus*, in ancient English law. A *villein in gross, villanus in grosso*, was one who did not belong to the land, but immediately to the person of the lord, and was transferable, like personal goods and chattels, from one owner to another.

GROSSASPERN. See Aspern.

GROSSENHAIN, a town of Saxony, capital of a cognominal bailiwick, in the circle of Dresden, stands in a fertile valley on the Röder, an affluent of the Elbe, 20 miles N.W. of Dresden. It has manufactures of woollen and cotton stuffs, and dye-works; and in 1849 contained 6943 inhabitants.

GROSSWARDEIN (Hung. *Nagy-Varad*), a city of Hungary, capital of the county of Bihar, on the left bank of the Körös, 140 miles E.S.E. of Buda. It is strongly fortified, and is the seat of a bishop, and of the several civil and military boards of the county. Besides the town proper it comprises eight suburbs, or rather distinct villages. The chief public buildings are the cathedral and some of the churches. It has several monasteries and nunneries, an ecclesiastical seminary, gymnasium, national school, and an orphan and other hospitals. It carries on a considerable trade in the products of the vicinity. In the neighbourhood are some hot mineral springs and valuable marble quarries. Pop. (1851) 21,221.

GROTESQUE, in its usual acceptation, is applied to anything distorted in figure; hence unnatural, wildly formed. Dryden says—"There is yet a lower sort of poetry and painting which is out of nature; for a farce is that in poetry which *grotesque* is in a picture: the persons and actions of a farce are all unnatural, and the manners false—that is, inconsisting with the characters of mankind; *grotesque* painting is the just resemblance of this."

In architecture, *grotesque* is applied to the light and fanciful ornaments used by the ancients in the decorations of the walls and some of the subordinate parts of their buildings. The term was thus applied from their having been long buried: the Italians call any subterranean apartment by the name of *grotta*, whence *grotesque*. *Arabesque* is also applied to the same kind of ornament which was much in use about the time of the Renaissance.

GROTIUS, Hugo, a celebrated Dutch scholar, jurist, historian, and miscellaneous writer, was born at Delft, April 10, 1583. His father, Jan Grotius or Groot, was a lawyer in that city. He was so much esteemed for his legal and general learning, that he was four times chosen burgomaster, and was made one of the three curators of the university of Leyden. He took great pains with the education of his son, who at the age of eight wrote good Latin verses, and at twelve is said to have converted his mother from the religion of Rome to that of the Reformed Church. After an elementary course at the Hague, under the famous Uytenbogoard, young Grotius was sent to Leyden, where his studies were superintended and directed by Joseph Scaliger. In 1597, when only fourteen, he defended, with much applause, public theses in mathematics, philosophy, and jurisprudence. Next year he accompanied Count Justin of Nassau and the grand-pensionary Olden Barneveldt on an embassy to the court of France. In that country he resided for nearly twelve months; and during this period he took the degree of LL.D. at the university of Orleans, though he had not then attained the age of seventeen. On returning to his native country, he was called to the bar, and pleaded his first cause at Delft in 1599. This year also witnessed his first published work, which was an edition of the Satyricon of Martianus Capella, with notes and commentaries. The work was undertaken at the instance of Scaliger, and was dedicated to the Prince of Condé. His reputation as a classical critic was increased by his edition of the *Syntagma Arateorum*, published in the following year. As this work relates to astronomy, it afforded him an opportunity of displaying his science as well as erudition. His brief notes on Lucan, accompanying an edition of the text, made their appearance in 1603. Some of his Latin verses had been printed so early as the year 1598, and others followed in 1599 and 1600. *Adamus Exul, tragœdia*, was published in 1601; but this tragedy he afterwards considered as too juvenile to be admitted into the general collection of his poems. His *Christus Patiens, tragœdia*, was printed in 1608, and was received with great applause. It was translated into English by George Sandys, and, at a more recent period, into German by D. W. Triller. With the former version he appears to have been much pleased. His third drama, *Sophompaneas, tragœdia*, was not published till 1617. It relates to the history of Joseph, whom he thus describes by an Egyptian name. Of this tragedy a Dutch version was undertaken by the celebrated poet Vondel. His *Prosopopeia* of Ostend was still more enthusiastically received, and was immediately translated into French by three different persons, and into Greek by Casaubon.

His first appearance at the bar produced a very favourable impression, and he soon rose to eminence. In 1607, that is, at the age of twenty-four, he was promoted to the important office of advocate-general of Holland and Zeeland. During the following year he married Maria van Reygersberg, a daughter of one of the first families in Zeeland. About this period he was occupied with a professional work, which appeared in 1609, under the title of *Mare Liberum, sive de Jure quod Batavis competit ad Indicana Commercia Dissertatio,* and involved its author in a violent controversy with Selden, Wellwood, and other English jurists. In 1610 he published a work *De Antiquitate Reipublicæ Batavæ;* and in the same year a Dutch translation of it, which was partly executed by his father. The book was afterwards translated into French. In 1613 Grotius was appointed pensionary, or syndic, of Rotterdam, and then fixed his residence in that city. In the course of the same year he was sent on a mission to the court of London, for the purpose of remonstrating against the arbitrary proceedings of the English, who claimed an exclusive right to the Greenland fisheries. His diplomatic exertions appear to have been attended with little or no success; but he was very graciously received by James VI., and had the satisfaction of forming a personal acquaintance with Isaac Casaubon.

Soon after this the famous Arminian controversy broke out, which ended so disastrously for Arminius and his partisans. Of these none had been more zealous than Grotius; and when the Stadtholder's influence had decided the day against him, he did not shrink from the punishment which he well knew would follow defeat. Barneveldt was beheaded; and Grotius, after an irregular and unfair trial, was condemned to perpetual imprisonment, and to have all his property confiscated. On the 6th of June 1619, in accordance with this cruel sentence, he was removed to the fortress of Loevestein, near the town of Gorcum in South Holland. His father was not allowed to visit him, and it was only with great difficulty that his wife obtained permission to share his cell. In literary pursuits he found at once the business and the pleasure of his life. He wrote some short annotations on the New Testament, and a work in Dutch verse on the truth of the Christian religion. For the use of his daughter Cornelia, he composed a metrical catechism in the same language. It was printed at the Hague in the year 1619, and he afterwards translated it into Latin verse. Another of his labours during his imprisonment was his introduction to the Dutch law, *Inleydinge tot de Hollandse Rechtsgelehrtheyt.* It was published in 1631, or perhaps earlier, and went through many editions, several of which contain the additions of Groenewegen, well known for his treatise *De Legibus abrogatis et inusitatis in Hollandia.* He translated Stobæus's fragments of the Greek poets, the Phœnissæ of Euripides, and the remains of Menander and Philemon. After he had been imprisoned for about twenty months, his wife devised a plan for his escape. He was in the habit of receiving books and clothes in a very large chest, which, for the first year, was examined regularly, and with great care by the officers. At last, however, they ceased their scrutiny; and Grotius' wife perceiving this, persuaded her husband to allow himself to be carried out in the chest. He consented, and after some hair-breadth escapes, found his way to Antwerp. After a short stay in that city he sought a more secure asylum in France. He reached Paris, April 13, 1621, and was warmly received by the literati of that city, and by the king himself, who gave him a pension of 3000 livres. He was at last joined by his wife, who had been detained in prison for about a fortnight after his escape, but had been released when it was found useless to detain her.

Being placed in a situation of comparative tranquillity, he now resumed his literary labours. Before the close of the year 1622, he published an *Apology* for himself and the party with which he acted. For this work sentence of death was pronounced against him in Holland, and the same penalty was denounced against all in whose possession it might be found. Grotius spent another year in Paris, editing and writing, and next year retired into the country to a villa near Senlis, which the kindness of the president De Mesmes had placed at his disposal. He here began the composition of his famous treatise *De Jure Belli et Pacis,* which was published in 1625. This work immediately made its author known all over Europe, and was translated into Swedish, English, and German, and twice into French. The treatise *De Veritate Religionis Christianæ* was published at Leyden in the year 1627, and the subsequent editions of this work have been very numerous. It has been translated into almost all the languages of Europe, and into various languages of Asia. An Arabic version was executed by the learned Dr Pococke.

In the meantime, his residence in France was not entirely free from inquietude and mortifications. His pension had never been paid with any degree of regularity; and he began at last to yearn for his own country. The death of Maurice of Orange, April 23, 1625, gave him hopes of returning in safety. He arrived at Rotterdam in the October of 1631; but his reception there, and in the other Dutch towns, was so extremely ungracious, that he was glad to escape from Holland with his life. He retired to Hamburg, where offers were made to him by the King of Denmark and several other princes. He accepted that of Oxenstiern, the chancellor of Sweden, who then governed that country in the minority of Christina. By him Grotius was appointed Swedish ambassador to the Court of France. He made his public entry into Paris, March 2, 1635. His mission was to try to secure the assistance of the French against the Imperialists; and though he had to contend with the statecraft, first of Richelieu, and afterwards of Mazarin, he upheld the honour and secured the interests of his adopted country with much address and effect. His diplomatic engagements, however, did not wholly interrupt his literary labours. During his stay in Paris he edited *Tacitus;* and, renewing his legal studies, published his *Florum Sparsio ad Jus Justinianeum*, Paris, 1642, 4to. Of this work, two different editions, both in duodecimo, were printed at Amsterdam in the course of the following year. It contains a series of annotations on the body of the civil law, and, as the title suggests, many of them are philological. At this busy era of his life he completed most of his theological works. The publication, in 1640, of his *Commentatio ad Loca quædam Novi Testamenti quæ de Antichristo agunt aut agere putantur*, exposed him to many severe animadversions from such men as Des-Marets, Du Moulin, Cocceius, and Slichtingius, some of whom accused him of being at heart a partizan of Papacy, others a follower of Socinus. This, however, did not prevent Grotius from publishing another volume of an equally liberal character, which bears the title of *Via ad Pacem Ecclesiasticam*, Amst., 1642, 8vo. His professed object is to conciliate the differences between the Protestants and the Papists. Although he was completely entangled in the cobwebs of Arminianism, the charge of Socinianism seems to be destitute of foundation. But with respect to the claim of the Romanists, it must be admitted to be somewhat more plausible. Grotius had found an asylum in a Catholic country: he may, in some degree, have been misled by his respect for antiquity, and attracted by the splendour of the Popish hierarchy. He expressed a great veneration for the Church of England. His *Via ad Pacem* was immediately attacked by several antagonists, the most formidable of whom was André Rivet, professor of divinity in the university of Leyden. Grotius defended himself in a work entitled *Votum pro Pace Ecclesiastica*, printed in 1642; and Rivet rejoined in the course of the following year. In 1645 Grotius published *Rivetiani Apologetici, pro Schismate contra Votum Pacis facti, Discussio;* and in 1646 Rivet endeavoured to assert the genuine peace of the church against suspicious mediators. Grotius was about this period engaged in a theological undertaking of much greater importance, namely, his annotations on the different books of the Old and New Testaments. His notes on the Old Testament and the Apocrypha were printed at Paris in 1644, in three volumes folio. His notes on the Gospels had been published in the same form three years earlier, but the concluding portions of this great work do not appear to have been printed before the year 1648. This is one of the works which have chiefly recommended his name to posterity; and writers of every denomination have agreed in ranking him among the ablest of biblical critics.

After having long discharged the functions of an ambassador, he at length solicited and obtained his recall. He had encountered many discouragements in the course of his negotiations; and the arrival of a Swedish agent, of whom he entertained a very unfavourable opinion, seems to have confirmed his wish to retire. Having embarked at Dieppe, the ambassador landed once more in his native country, and was received with due honour at Amsterdam. He proceeded by sea to Hamburg, where he arrived about the middle of May 1645. On reaching Stockholm, he was very graciously received by the queen, who made him ample promises, and was anxious to retain him in her service. The climate of Sweden, however, did not suit his health, and he determined to quit it. Christina loaded him with gifts; and, with these rewards of his faithful services, he sailed, August 12, for Lubeck. The vessel was speedily overtaken by a storm, and on the 17th was driven ashore near Danzig. Travelling in an open carriage, he arrived at Rostock on the 26th, in a very feeble and exhausted condition. Every effort was made to save his life, but in vain. He expired, August 28, 1645, in the sixty-third year of his age. His remains were conveyed to Delft, and were deposited in the tomb of his ancestors.

He had prepared for the press various works which he did not live to publish. Soon after his death one of these appeared under the following title—*De Imperio Summarum Potestatum circa Sacra*, Lutet. Paris, 1647, 8vo. This was soon followed by *Philosophorum Sententiæ de Fato, et de eo quod in nostra est potestate, collectæ partim et de Græco versæ*, Paris, 1648, 4to; Amst., 1648, 12mo. Next appeared *Historia Gotthorum, Vandalorum, et Langobardorum, partim versa, partim in ordinem digesta*, Amst., 1655, 8vo. His history of his native country was published not long afterwards—*Annales et Historiæ de Rebus Belgicis*, Amst., 1656, fol.; Amst., 1658, 12mo. This very title at once suggests Tacitus as the writer's model, and his style is evidently formed on that of the ancient historian. Another posthumous publication was his tract *De Eucharistia*, which was fiercely attacked by Salmasius, under the assumed name of Simplicius Verinus. A very ample and interesting collection of his letters, consisting of nearly one thousand pages in double columns, was published by two of his grandsons: *Epistolæ quotquot reperiri potuerunt; in quibus præter hactenus editas, plurimæ theologici, juridici, philologici, historici, et politici argumenti occurrunt*, Amst., 1687, fol. The poetical version of the *Anthology*, on which he had bestowed much labour, was not published till a century and a half after his death. The manuscript at length came into the possession of De Bosch, a man of learning and taste, who published the work in a splendid form, with copious illustrations of his own, under the title of *Anthologia Græca, cum versione Latina Hugonis Grotii, edita ab Hieronymo de Bosch*, Ultrajecti, 1795–8, 3 tom. 4to.

Gulielmus Grotius, or Willem de Groot, the brother of Hugo, deserves a brief notice. Being bred to the legal profession, he became eminent at the bar, and was appointed advocate to the East India Company. He was a man of erudition, and the author of several works. One of these is an *Enchiridion de Principiis Juris Naturalis*, in which he illustrates the principles of a science that was so deeply indebted to another member of the same family. Another of his works, which was published after his death, and which is still held in great estimation by civilians, bears the title of *Vitæ Jurisconsultorum quorum in Pandectis extant Nomina*, Lugd. Bat., 1690, 4to. He appears to have been a most affectionate brother, and to have sympathized very deeply in the fortunes of a kinsman whose moral and intellectual endowments reflected so much lustre on the family to which he belonged.

GROTTAMARE, a town of the Papal States, delegation and 14 miles S.S.E. of Fermo, on the Adriatic. It has large manufactories of liquorice and cream of tartar, and sugar refineries. Pop. 4050.

GROTTO, properly Grotta, a cave, natural or artificial, in the face of a rock or a mountain.

Among the more remarkable artificial works of this kind may be mentioned the famous *Grotta di Pausilippo*, which is a straight passage cut through the rock from Naples to Puzzuoli, about 1000 paces in length, 80 or 90 feet high, from 24 to 30 feet wide, and forming the main road for the daily traffic of a very populous district. See Pausilippo. But the most remarkable examples of artificial caverns in the world are to be found in the ancient Petra, which may be called a city of caves or grottoes. See Petra.

Of natural grottoes, it will only be necessary here to name a few of the most remarkable in their several ways, in order to facilitate reference to those parts of the work where they are more particularly described. Among these are the celebrated caverns of Illyria, in the Julian Alps—mountains of calcareous formation, and abounding in caves; while they present, particularly in the eastern part, the natural phenomena of subterranean rivers, lakes, cascades, and other curiosities, such as are unknown in any other part of Europe. The most magnificent of these is described under ADELSBERG, which see. Under separate heads, or those of the countries where they occur, will be found, together with many others of note, descriptions of the following famous caves:—Baumans Höhle, a series of ossiferous caverns in Germany (see BAUMANS HÖHLE); the ossiferous cave of Kirkdale in Yorkshire (see KIRKDALE); the Mammoth Cave of Kentucky, said to be 8 or 10 miles in length (see KENTUCKY); the Epsom Salt Cave, 2 miles long (see INDIANA); the famed cavern of Antiparos, an island in the Grecian Archipelago (see ANTIPAROS). The caves and excavations of the Peak district in Derbyshire are very celebrated. An account of these is to be found in the illustrated work entitled *Peak Scenery*, by E. Rhodes.

The *Grotta del Cane* (*i.e.*, dog's cavern) is a small cave near Puzzuoli, about 7 miles S.W. of Naples, remarkable for the noxious quality of its air. This is caused by the carbonic acid which issues from crevices in the floor of the cave, and which fills the lower part to the level of the entrance, when it flows out by its superior gravity. Hence a man may enter the cave with impunity; while a small animal, such as a dog, is speedily destroyed by the noxious gas it must necessarily respire. See CAVE, vol. vi., p. 350.

GROUP, in *Painting* and *Sculpture*, an assemblage of two or more figures of men, beasts, or other things, which have some apparent relation to each other

GROUSE, a heath-cock. See index to ORNITHOLOGY.

GROUT, among builders, mortar rendered fluid by the addition of water: also a mixture of plaster and fine stuff, putty, or coarse stuff, used in finishing ceilings, for mouldings, and sometimes for setting walls.

GROVE, a small wood or cluster of trees. Among the ancients groves were held in great veneration. The *proseuchæ*, and high places of the Jews, whither they resorted for the purposes of devotion, were probably situated in groves (see Joshua xxiv. 26). The *proseuchæ* in Alexandria, mentioned by Philo, had groves about them; for he complains that the Alexandrians, in a tumult against the Jews, cut down the trees of their *proseuchæ*. There were groves near many of the Roman temples, which were consecrated to some god, and, as Cicero alleges, called *luci* by antiphrasis, *a non lucendo*, as being shady and dark.

GROWTH, the gradual increase which takes place in animal or vegetable bodies by the addition of matter through ducts and secretory vessels.

Among the numerous instances recorded of an extraordinary degree of early development in the human frame, not the least remarkable is that of a boy who was exhibited before the Academy of Sciences at Paris in the year 1729. This boy, though then only seven years of age, measured four feet eight inches and four lines in height. It was stated that at two years of age he began to exhibit signs of pubescence, which soon afterwards were completely developed. At the age of four he was able to toss the common bundles of hay in stables into the horses' racks; and at six he could raise as much as a sturdy fellow of twenty. But though he thus increased in bodily strength, his understanding was not greater than is usual with children of his age, and their playthings were also his favourite amusements. A similar instance of precocious virility was exhibited to the great meeting of *naturforschers* (natural philosophers) at Hamburg in 1830; and another more recently to the British Association. It has been generally observed that such abnormal precocity is indicative of premature decay, and that few of these individuals ever attain the ordinary term of manhood.

For the physiological consideration of the subject of growth in plants and animals, see BOTANY, vol. v., p. 99–103, and PHYSIOLOGY.

GRUB, a small worm; a name more particularly applied to the hexapod worms produced from the eggs of beetles, and which are eventually transformed into winged insects.

GRUBENHAGEN, a principality in the kingdom of Hanover, comprised in the *Landrostei* or province of Hildesheim. It consists of two unequal parts separated by the Harz Mountains, the larger being S.W. of that range. Area about 310 square miles. The Harz Forest covers the greater part of the principality, some of the hills of which are 2700 feet in height, and are clothed to their summits with pines. The principal pursuit of the inhabitants is mining. Its mineral wealth is considerable, comprising gold, silver, copper, lead, iron, zinc, vitriol, and sulphur. The climate is cold, moist, and gloomy. Pop. 87,280.

GRUNBERG, a town of Prussian Silesia, capital of a cognominal circle in the government of Liegnitz, and 36 miles N.N.W. of Glogau. It is surrounded by walls, and has flourishing manufactures of woollen cloths, printed cottons, and leather. The vine is extensively cultivated in the vicinity. Pop. (1849) including suburbs, 10,587. There is another town of this name in Hesse-Darmstadt, province of Upper Hesse, 14 miles E. of Giessen. Pop. about 2500.

GRUS (Lat. a *crane*), a constellation of the southern hemisphere.

GRUTER, JAN, a distinguished scholar and critic, was born at Antwerp in 1560. His father was a Fleming, but his mother, whose name was Tishem, was an Englishwoman, and able, from her own knowledge of the classics, to instruct her son in them. Being obliged to fly Holland for siding with the Reformed faith, Gruter's family came to England, and the young Gruter, after studying for some years at Cambridge, returned to his native land, and graduated at Leyden. After this he seems to have taught successively at Rostock, Wittemberg, and Heidelberg, in which last city he resided till his death in 1627, despite of tempting offers of professorships in France, Denmark, and Italy. It is not known what chair he held in Heidelberg, but he was also conservator of the university library. His knowledge of bibliography enabled him to amass a large private library, which, however, he lost in the memorable siege of Heidelberg in 1622.

Gruter at one time enjoyed a vast reputation for learning, and there is no doubt that he was as good a scholar as a man of solid faculties and unwearied industry can alone be. But though his erudition was great, his mental power, beyond the mere faculty of acquisition, seems to have been small; and, accordingly, we do not find that he has made any valuable contribution to any department of scholarship. Besides editions of some of the Latin classics which involved him in highly indecent controversies with Pareus and others of his contemporaries, Gruter compiled a most valuable work, published at Heidelberg in 1601, under the title of *Inscriptiones antiquæ totius orbis Romani*. Gruter is said to have written a book every month, but the entire list of his works preserved in Nicéron only comprises thirty-two. These, as has been already mentioned, are chiefly the later Latin classics, and possess but little critical value.

GRUYÈRE (German *Greyerz*), a town of Switzerland, canton of Freiburg, 15 miles S. of the town of that name, on a hill, the summit of which is crowned by one of the best preserved feudal castles in Switzerland. Its population does not amount to 400, but the district is noted for producing the celebrated cheese to which it gives name.

GRY, a measure containing one-tenth of a line. A line is one-tenth of a digit, and a digit one-tenth of a foot, and a philosophical foot one-third of a pendulum whose vibrations, in the latitude of forty-five degrees, are each equal to one second of time, or one-sixtieth of a minute.

GUADALAJARA, a province of Spain, in New Castile, bounded on the N. by the provinces of Segovia, Soria, and Saragossa, S. by Cuenca, E. by Saragossa and Teruel, and W. by Madrid. In Atienza in the north of this province are some of the loftiest summits in the Peninsula, having their culminating point in the Peña de la Bodera. The soil varies considerably, but is generally of good quality. Pasture occupies the larger portion of the surface in the higher tracts. The districts of Tamajon are admirably adapted for cereals. Alcarría, however, matures all kinds of crops common to the latitude. Iron and lead are the only minerals; the former is very abundant, and has been worked from the remotest periods; the latter occurs but in small quantities. The principal productions are wheat, barley, oil, wine, silk, saffron, and flax; but the chief wealth of the province consists in sheep and wool. Manufactures and trade have been gradually declining for many years. For administration the province is divided into nine districts, of which Guadalajara is the capital. The estimated population of this province is (1856) upwards of 200,000; and the area is 1951 English square miles.

GUADALAJARA, a city of Spain, capital of the province of the same name, in New Castile, is situated on the eastern bank of the Henares, 38 miles N.E. of Madrid, and is 2330 feet above sea-level, in N. Lat. 40. 33. It is ill built, has five parish churches, seven conventual churches besides several chapels, four convents, an Ionic sessions and town-house, built in 1585; a handsome theatre, lying-in, civil, and military hospitals; barracks; the palace of the Duque del Infantado; a Latin, normal, and various other schools. An extensive Roman aqueduct supplies six public fountains; and there are four public promenades. The principal manufactures are wine, oil, soap, earthenware, and woollens. The cloth manufactory which was formerly carried on in behalf of the government, is now in private hands. The trade of the city consists chiefly in grain, flax, fruits, clothes, and silk.

Guadalajara is the chief town of the *Arriaca* of the Romans, and was taken by the invading Moors (A.D. 714), who bestowed on it the name of "Guidalhichara," or "Guadalaruaca," of which its present name is a corruption. Pop. about 7500.

GUADALAJARA, a state and town of Mexico. See MEXICO.

GUADALCANAL, a town of Spain, province of Andalucia, 50 miles N. of Sevilla, and 70 S.E. of Badajoz, near the Vanalija. Its principal manufactures are soap, leather, hats, oil, wine, and brandy; and its trade consists chiefly in grain, fruits, wine, and cattle.

GUADALETE, a river of Andalucia, in Spain. It rises in the Sierra del Peñol, or San Cristoval, province of Cadiz, flows W.S.W. near the town of Bornos, and past Arcos, and falls into the Atlantic near Matagorda, 3 miles E. of Cadiz, after a course of 95 miles.

GUADALOUPE, or GUADELOUPE, one of the Leeward group of islands in the West Indies, and one of the most important colonies of France, and situated in N. Lat. 16. 20., W. Long. 62. It consists properly of two islands separated from each other by a narrow channel, about 5 miles in length, by from 30 to 100 yards wide, and with depth sufficient for vessels of 60 tons. This channel, called *La Rivière Salée*, or Salt River, runs nearly N. and S., and has a large bay at each end, that on the N. being called the *Grand Cul-de-Sac*, that on the S. the *Petit Cul-de-Sac*. The western or larger island, called Guadaloupe proper, or *Basse Terre*, is 27 miles in length, by 15 in breadth; the eastern, or *Grande Terre* is nearly 30 miles long, by from 10 to 12 broad. Guadaloupe proper is of volcanic formation, and is traversed from N. to S. by a ridge of hills having a medium height of 2296 feet. Its principal peaks are *La Souffrière*, an active volcano 5108 feet high, and *Grosse-Montagne*, *Deux-Mamelles*, and *Piton de Bouillante*, extinct volcanoes. It is copiously watered by numerous small streams, two of which, the *Goyave* and the *Lezarde*, are navigable for small craft. The soil is fertile, and the surface is agreeably diversified by hill and dale, wood and garden. The products, natural and cultivated, are those of the West Indies generally. The principal town, *Basse Terre*, stands on the S.W. coast. It is the residence of the governor, and has some fine public buildings, fountains, and gardens, and about 6000 inhabitants. *Grande Terre*, unlike Guadaloupe proper, is marshy, sterile, and flat, nowhere rising more than 115 feet above the sea. Its chief town, *St Louis* or *Point à-Pitre*, the former capital of the island, is at the S. entrance to the Salt River, and has an excellent harbour. It formerly contained about 15,000 inhabitants, but was almost entirely destroyed by an earthquake on 8th February 1843, on which occasion 4000 of its inhabitants perished. The climate is humid, and hurricanes and earthquakes are frequent. The rainy season lasts from the middle of July to the middle of October. The chief exports are sugar, molasses, rum, cotton, coffee, dye-woods, and copper. The sugar crop amounts to about 60,000 hogsheads annually. A considerable quantity of fish is taken in the neighbouring seas. The government consists of a governor, with a privy council of six, and a colonial council of thirty members. The government of Guadaloupe comprises, besides that island, those of *Marie-Galante*, *Desirade*, *Les Saintes*, and the northern portion of *St Martin*. *Marie-Galante* lies 14 miles S.S.E. of Guadaloupe, and is about 12 miles in length, by 8 in breadth. It is traversed from N. to S. by a range of hills running parallel to the E. coast, where it presents a front of high and precipitous rocks. The W. and N. sides of the island are level; and parallel with the former is a narrow lagoon, 7 or 8 miles in length, separated from the sea by a low narrow tract of land. The island abounds in woods, particularly the wild cinnamon tree. Its principal town, *Grandbourg* or *Basse Terre*, stands near the S.W. point. *Desirade*, or *Deseada*, lies about 4 miles E. from the S.E. extremity of *Grande Terre*, and is about 8 miles long by 3 wide. It rises from the sea with a steep ascent, and then extends in a table-land, which consists of limestone rocks, in which many caverns occur, but it is without water. The soil in some places is of a deep black mould, and fertile; in others it is sandy and unproductive. The only anchorage is at the *Anse-Galet*, on the E. side of the island. *Les Saintes* are a group of rocky islets 6 or 7 miles S. of Guadaloupe, and consist of lofty and steep peaks, some of which are united by flat ground and ridges of inferior elevation. The two largest are called *Terre d'en Haut* and *Terre d'en Bas*. *St Martin* is a small island immediately S. of the British island of Anguilla, in N. Lat. 18. 5., and W. Long. 63. 6. Its form is nearly that of an equilateral triangle, each side being about 7 miles in length, and comprising an area of about 33 square miles. It is deeply indented with bays and lagoons, some of which afford good anchorage. The surface is generally hilly, the highest point being 1361 feet above the sea. It was colonized by the French and Dutch in 1638, but these were expelled by the Spaniards, who themselves abandoned the island in 1750, and the original settlers resumed possession. The southern portion of the island belonged to the Dutch. Guadaloupe was discovered by Columbus in 1493. In 1635 the French established a settlement upon the island, and retained possession of it till 1759, when it was taken by the English. It was subsequently, on several occasions, taken and retaken by these nations, and was finally ceded to France in 1814. Pop. (1854) 132,810. Slavery was abolished here by a decree of the French Republic in 1848, at which time about 100,000 persons were emancipated.

GUADALQUIVIR, a river of Spain, province of Andalucia, the fifth in point of length, and the sixth in the number and importance of its tributaries in the peninsula. It rises in the Sierras de Alcaráz, Segura and Cazorla, and falls into the ocean by Sanlucar de Barrameda, after a course of 412 miles. It flows first in a northerly direction, then W., then S.W., and ultimately towards the S., draining a basin of 25,680 square miles. In its course it passes through and drains the four provinces of Jaen, Córdoba, Sevilla, and Cadiz. Its source-spring is 4 miles W. of the town of Quesada, Sierra de Cazorla, province of Jaen.

GUADALUPE, a town of Spain, New Castile, 100 miles S.W. of Toledo. It is situated on the southern slope of Monte Altamira. The monastery of Jeronimo, which is in the centre of the town, was formerly the Loretto of Central Spain, and still contains many valuable works of art. Pop. 4000.

GUADI is the Spanish pronunciation of the Moorish *Wadi*, "a stream with its valley." It occurs in the names of numerous rivers of Spain.

GUADIX, a royal and episcopal city of Spain, province of Granada, and chief town of the department of the same name. It stands on the northern slope of the Sierra Nevada, and above the left bank of the River Guadix. It is said to have been the first Bishop's see erected in Spain; and is surrounded by ancient walls, and contains a fine cathedral, partly in the Corinthian style. The ruins of an ancient castle stand on a fine site, commanding the town. The principal manufactures are saltpetre, earthenwares, hempen goods, hats, silk fabrics, sail-cloth, and cutlery; and the trade is chiefly in silk, wool, cotton, flax, corn, liqueurs, and various other articles. The Moors made a valiant defence here and maintained their position till 1589. Pop. nearly 12,000.

GUAIACUM, a resinous substance, of a greenish-brown colour, an aromatic smell, and a bitterish acrid taste. It is the produce of *Guaiacum officinale*, a tree that grows in the warmer parts of America, especially St Domingo, and which is popularly known as *Lignum-vitæ*. This resin is used chiefly in pharmacy, but is an unimportant medicine.

GUAM, or Guahon, one of the Ladrone Islands. It is a large island, about 120 miles in circuit, high and shelving on each side, and fenced with steep rocks, against which the surf perpetually beats. There is a bay on the west side, in which there are several small harbours. The climate is mild and salubrious, and the soil yields a great profusion of vegetables and fruits, particularly guavas, bananas, cocos, oranges, and limes. The population is uncertain. The island was discovered by Magellan in 1521, and at that time the inhabitants—a wild and savage race—were numerous. Long. 143. 15., Lat. 13. 10.

GUAMANGA, or Huamanga, a city of Peru, capital of the department of Ayacucho, on an affluent of the Apurimac, 140 miles W.N.W. of Cuzco. It was founded by Pizarro on the site of an Indian village of the same name, for the convenience of trade between Cuzco and Lima. It has a fine cathedral, several other churches, monasteries, nunneries, and a university. Pop. about 20,000.

GUANAJUATO, a state and city of Mexico. See Mexico.

GUANCAVELICA, or Huancabelica, a town of Peru, capital of a cognominal department, in a ravine of the Andes, 11,000 feet above the sea, and 80 miles W.N.W. of Guamanga. The district is bleak and cold, but is famous for its mines of gold, silver, and particularly mercury. Pop. about 6000.

GUANO, the solid excrement of carnivorous sea-birds, which is found in immense quantity on the coasts of South America, and in other tropical countries, as South Africa. The analysis of this very powerful manure, its varieties, adulterations, market prices, agricultural application, &c., are fully detailed under Agricultural Chemistry, vol. ii., p. 408–11; see also Agriculture, vol. ii., p. 299.

Guano, or *Huano*, is the Peruvian term for manure. This substance, though brought to Europe for the first time in 1840, has been employed in agriculture by the Peruvians from the age of the Incas downwards. The chief sources of supply at present are the Chinca islands, off the coast of Lower Peru, and the Lobos islands, opposite to Lambayeque in Upper Peru. Chinca, the chief of the group bearing that name, has been estimated to contain the enormous quantity of seventeen millions of tons; and that of the remainder of the group is given at twenty to twenty-five millions. The supply on the Lobos islands, though not so extensive, is yet very large. There are also other islands and places on the coast that afford considerable supplies of guano; so that upon the whole, for all practical purposes, the supply may be considered as inexhaustible.

So ignorant were the governments of Peru and Bolivia of the value of this article, that they sold to private parties the sole right to ship guano for the term of nine years for the trifling sum of $40,000; but soon perceiving the ruinous nature of the contract, the Peruvian government cancelled it two years afterwards (in 1841), on the ground of enormous public lesion, and ignorance of the value of the privilege conceded. This had the effect of opening up the trade for a time; but the monopoly system was revived in the course of a year or two by the Peruvian government, whose agents (Messrs Gibbs & Sons, of London) are now the sole importers in this country, though of late much has been sent direct from Peru to Spain. The exorbitant price demanded for this manure has occasioned much complaint; and it is to be hoped that some measures may be devised for reducing the price to a fair commercial rate. (M'Culloch's *Commercial Dictionary*.)

The total quantity of guano imported in 1854 amounted to 235,111 tons: against 123,166 tons in 1853; 129,889 tons in 1852; 243,014 tons in 1851; and 116,925 tons in 1850. Of the above 235,111 tons, 221,747 tons came from Peru; 3187 from British South Africa; 1502 from the United States; 4249 from Chili.

GUARANIS, an aboriginal people of South America. See South America, vol ii., p. 691.

GUARANTEE, in law, an obligation undertaken by one party that another shall pay or perform that for which he is or may become liable to a third party. In mercantile transactions in Scotland it may be constituted in any way by which the consent of the guarantee obligant is truly and freely given; but it can only be proved by his oath or writing. The evidence of witnesses is inadmissible, unless the obligation was undertaken as an integral part of a transaction relative to moveables, provable by witnesses, or that something followed on the faith of it, with the knowledge of the guarantee obligant, by which the rights of parties were materially affected. In England it is enacted by statute, that "No action shall be brought whereby to charge the defendant upon any special promise to answer for the debt, &c., of another person, unless the agreement on which such action shall be brought, or some memorandum or note thereof, shall be in writing, and signed by the party to be charged therewith, or some other person thereunto by him lawfully authorized." The construction of all such obligations is never extended beyond their obvious meaning, and they are only understood to apply to future, unless they expressly include past transactions. All their conditions and limitations must be carefully regarded, otherwise they become void. If so expressed or intended, however, such obligations may be of the most unqualified character; they may be unlimited in amount, and indefinite as to time. When the guarantee obligant is compelled to pay, he has an action of relief against the principal debtor; but that party, being primarily liable, must first be sued by the creditor; and whatever he does towards the extinction of the claim of the creditor, or whatever the creditor recovers from him or his estate, goes so far to relieve the guarantee obligant, who can also plead against the creditor any defence which could be competently pleaded by the principal debtor. Where more persons than one are bound together in a guarantee obligation, any of them seeking relief from the others of a share of his loss must communicate to them a share of any security which he may hold over the estate of the principal debtor, or of any abatement he may have obtained from the creditor. A guarantee obligation may be extinguished by the extreme neglect of the creditor; as, for example, by his failing to take advantage of a security in his power, omitting to negotiate a bill, inadvertently giving up funds of the principal debtor over which he had a right of lien or retention, or renouncing any security over his estate. In like manner, if he compound with, or discharge the principal debtor, without the concurrence of the guarantee obligant, the guaranty is at an end; excepting under a commission of bankruptcy in England, or a sequestration in Scotland, where the creditor may, by acquiescence, allow the principal debtor to be discharged, and may accept a composition, without discharging the guarantee, provided the guarantee obligant has previously been duly warned and called on to satisfy the debt. (M. L.)

GUARD, in military affairs, a body of men appointed to watch a position, and withstand an attack, if attempted.

GUARDS, The, a general name for the regiments of Household Troops.

Horse Guards, in England, were originally gentlemen chosen for their bravery to be intrusted with the guard of the king's person. They were divided into four troops. The first was raised in the year 1660, and the command given to Lord Gerard; the second in 1661, and the command given to Sir Philip Howard; the third in 1693, and the command given to Earl Feversham; the fourth in 1702, and the command given to Earl Newburgh. Each troop had one colonel, two lieutenant-colonels, one cornet and major, one guidon and major, four exempts and captains, four brigadiers and lieutenants, one adjutant, four subbrigadiers and cornets, and sixty private men. The four troops were afterwards turned into two regiments of Life Guards.

The *Horse Grenadier Guards* were divided into two troops. The first troop was raised in 1693, and the command given to Lieutenant-General Cholmondeley; the second in 1702, and the command given to Lord Forbes. Each troop had a colonel, a lieutenant-colonel, a guidon or major, three exempts and captains, three lieutenants, one adjutant, three cornets, and sixty private men.

The *Yeomen of the Guard* were first raised at the coronation of Henry VII., Oct. 30, 1485. They are a superior kind of Foot Guards to the royal person, and are generally called by the nickname of *Beef-Eaters*. (See Appellation.) They were originally fifty in number, and of larger stature than ordinary, each being required to be over six feet in height. This band was afterwards increased to a hundred, and seventy supernumeraries; and when one of the hundred died, his place was supplied out of the seventy. Their first captain was the Earl of Oxford, in 1486.

The *Foot Guards* are regiments of foot appointed to guard the royal person and palace. They were raised in 1660, when the command of the first regiment was given to Thomas Lord Wentworth; that of the second to General Monk, then Duke of Albemarle; and that of the third to the Earl of Linlithgow. The second regiment is always called the Coldstream Guards, from a town in Berwickshire, where it was first embodied. This regiment is older than the first, having been raised sooner; and, from being commanded by General Monk, was called Monk's regiment, in compliment to whom it was made one of the three royal regiments by Charles II.

Scotch Guards, a celebrated band which formed the first company of the ancient *Gardes du Corps* of France. In the ancient intercourse between the two countries, the natives of Scotland had often distinguished themselves in the service of France. On this foundation the company of Scotch Guards, and the company of Scotch Gendarmes, were instituted; both of them owed their institution to Charles VII. of France, by whom the first standing army in Europe was formed, in the year 1454.

The ancient rights and privileges of the Scottish Life Guards were most honourable. The author of the Ancient Alliance between France and Britain says, "On high holidays, at the ceremony of the royal touch, the erection of knights of the king's order, the reception of extraordinary ambassadors, and the public entries of cities, there must be six of their number next to the king's person, three on each side; and the body of the king must be carried by these only, wheresoever ceremony requires. They have the keeping of the keys of the king's lodging at night, the keeping of the choir of the chapel, the keeping the boats where the king passes the rivers; and they have the honour of bearing the white silk fringe in their arms, which in France is the *coronne couleur*. The keys of all the cities where the king makes his entry are given to their captain in waiting or out of waiting. He has the privilege, in waiting or out of waiting, at ceremonies—such as coronations, marriages, and funerals of the kings, and at the baptism and marriage of their children—to take duty upon him. The coronation robe belongs to him; and this company, by the death or change of a captain, never changes its rank, as do the three others."

This company's first commander, who is recorded as a person of great valour and military accomplishments, was Robert Patillock, or Patullo, a native of Dundee; and the corps, ever ardent to distinguish itself, continued in great reputation until the year 1578. From that period the Scotch Guards were less attended to, and their privileges came to be invaded. In 1612 they presented a remonstrance to Louis XIII. on the injustice they had suffered, and placed before him the services they had rendered to the crown of France. Attempts were then made to re-establish them on their ancient foundation; but the negotiation for this purpose proved ineffectual. The troops of France became jealous of the honours paid to them; the death of Francis II., and the return of Mary to Scotland, at a time when they had much to hope for, were unfavourable to their pretensions; the change of religion in Scotland, and the accession of James VI. to the throne of England, altogether disunited the interests of France and Scotland. The Scotch Guards of France had therefore latterly no connection with Scotland except in name.

Guard-Boat, a boat appointed to row the rounds among ships of war laid up in a harbour or in ordinary, and to observe that their officers keep a good look-out, &c.

Guard-Ship, a vessel of war appointed to superintend maritime affairs in a harbour or river, and to see that the non-commissioned ships have their proper watchword duly kept, by sending guard-boats round them every night.

GUARDAMAR, a town of Spain, province of Valencia, near the right bank of the Segura, 2 miles from the sea, and 20 miles S.S.W. of Alicante. Pop. nearly 3500.

GUARDIA, the name of several places in Spain; of these the principal are—1. La Guardia, a town of New Castile, near the left bank of the Cedron, 30 miles E.S.E. of Toledo. Its manufacturing industry is confined to wine, oil, soap, saltpetre, linens, baize, and serge. The trade consists chiefly in agricultural produce, cattle, and hemp. Pop. nearly 4000.—2. A town in Andalucia, on a rock surmounted by an old fort, near the left bank of the Jaen. The chief manufactures are delft, linens, and shoes; and there is some trade in agricultural produce, and fruits. Pop. nearly 2500.

GUARDIAN, in *Law*, generally signifies one who has the charge of the person, education, and property of children, or of any one labouring under some incapacity for managing his own affairs.

A father is by nature the guardian of his children. On his death the office is devolved on those who may have been appointed by him, or if they decline to accept, the law appoints the nearest relatives on the father's side. The Roman law, in the event of no appointment by the father, generally committed the guardianship of both the minor and his estate to him who, by the death of the minor, would succeed to his inheritance; presuming that he would take the best care of the estate who had the nearest prospect of succeeding to it. But both the law of England and Scotland commit only the care of the estate to the heir-apparent; and, wisely considering that he may not be sufficiently careful of a life standing in the way of his own succession, intrust the custody of the pupil to the mother if alive, or, if dead, to the nearest relatives on the mother's side. Guardians may also be appointed by a stranger for the management of an estate left to the minor by such stranger, or by a judge before whom a suit may depend, in which a father may have an interest adverse to his child; and in all cases where, from any cause, a person cannot manage his own affairs, and his relatives are unwilling or disqualified to act for him, the law, in one form or another, provides a manager or guardian. In these last cases, security, and a strict account of his intromissions, are exacted from the guardian. The guardianship of a father over his minor daughter is at an end when she marries a person who has attained majority—the husband being the guardian of his wife.

Both in England and in Scotland, as by the Roman law, guardians are appointed for the protection of the persons and estates of idiots and lunatics. Guardians for children are distinguished as tutors and curators. The former act altogether in the place of the pupil, who is held incapable of giving consent; and the latter act along with the minor (that is a person past pupilarity, but still under majority), who is not held incapable, though immature. The powers of both of these guardians resemble those of a parent; and may be comprehended in the word administration, or management. They can neither sell their ward's estate, nor alter its succession.

In Scotland, the court, on evidence that a person of full age is of a weak and facile disposition and wasteful habits, will appoint, and such a person may even by his own voluntary act appoint, a guardian, called an interdictor, without whose consent (the public being previously warned in a prescribed form) he can do nothing towards the alienation of his heritable estate. This sort of guardianship can only be removed by the court on evidence, either that it was originally unnecessary, or that the party has become provident of his own affairs; or, when constituted voluntarily, by the consent or death of the interdictor. (M. L.)

Guardian of the Spiritualities, the person to whom the spiritual jurisdiction of a diocese is committed during the vacancy of the see. A guardian of the spiritualities may likewise be either such in law, as the archbishop is of any diocese within his province, or by delegation, as he whom the archbishop or vicar-general for the time appoints. Such guardian has power to hold courts, and grant licenses, dispensations, probates of wills, &c.

Guardian of the Temporalities, one appointed by the crown during such vacancy, to take care of the goods and profits, and to render an account thereof to the Exchequer.

GUARINI, Giovanni Battista, a celebrated Italian poet, was born at Ferrara, on the 10th of December 1537. He studied at the university of Padua, under the direction of his father Alexander, to whom he owed the greater part of his acquisitions in knowledge, and more particularly his taste for poetry. Guarini succeeded his father in the chair of humanity at Ferrara, though then scarcely twenty; but some lyrical compositions already published by him had inspired such hopes of future eminence as fully justified his promotion. Called to the court of the Duke of Ferrara, at that period the resort of men of the first talents in Italy, he there became acquainted with Tasso, who was seven years younger than himself, gained his friendship, and afterwards became his most zealous defender and ardent panegyrist. The duke having knighted Guarini, intrusted him with several important missions to the different courts of Europe; but, during fourteen years that he remained in the service of this prince, he never obtained the slightest recompense, and in the meanwhile had expended the greater part of his fortune. Guarini complained of this; the duke, conscious that his complaints were well founded, became irritated; recrimination ensued, and the poet retired in disgust from court. Some time afterwards, he passed into the service of Emanuel Philibert, Duke of Savoy, and next into that of Vincent, Duke of Mantua; but as, at both courts, he received much praise and no salary, he at length retired to his estate of Guarini, near Reggio. Having lost his wife, he formed a design of taking holy orders, and with this view repaired to Rome. But Guarini had too much ambition to persevere in such a scheme; and, accustomed as he had been to the gaieties of courts, he found himself but little disposed to relish the sweets of retirement. He accordingly returned to Ferrara, and thence proceeded to Florence, where the Grand Duke Ferdinand loaded him with presents and honours. His good fortune, however, was not of long duration. The grand duke, wishing to establish suitably a lady of Pisa to whom he had been attached, induced one of the sons of Guarini to marry her without the knowledge of his father, whose delicacy on the point of honour was well known to him. When the latter was made acquainted with the marriage of his son, his indignation knew no bounds; and, justly offended at the despotic proceeding of the grand duke, he quitted Tuscany without the ceremony of taking leave. But after passing some months with his protectress, the Duchess of Urbino, he became reconciled to the Duke of Ferrara; and in 1603 he was sent by that prince to Rome as ambassador to Pope Paul V. Guarini, however, was constantly the sport of fortune; for, besides the ingratitude of the great, of which he had had painful experience, his life was embittered by domestic misfortunes. He had lost in the flower of her age a wife whom he adored; and his three sons frequently stirred up domestic quarrels about the division of a fortune almost entirely exhausted. But the most severe blow he received was by the tragical death of his daughter Anna. On returning from one of his journeys, he went to visit his beloved child, and when he fondly expected to fold her in his arms, he found only a bloody corpse. She had just fallen a victim to the jealousy of a suspicious and violent husband. But all these misfortunes did not prevent Guarini from occupying himself with his works, the principal of which are, *Il Pastor Fido*, a pastoral tragi-comedy in five acts, and in verse, which passed through forty editions during the lifetime of the author, and by which his name has been rendered for ever famous; *Verrato Primo*, Ferrara, 1588; *Verrato Secondo*, Florence, 1595; *Il Segretario*, dialogo, Venice, 1594, 1600; *Idropica*, a comedy in five acts, and in prose, Rome, 1614. A very beautiful edition of the works of Guarini was published at Ferrara, in 1737, four vols. 4to, with superb engravings, and very beautiful vignettes. The second volume contains the lyrical compositions of the author, some of which are highly esteemed; the fourth is filled with annotations and apologies or defences of the *Pastor Fido*, by different authors. Guarini also left a treatise on public liberty, which reasons of state, however, prevented him from publishing. His death took place at Venice, whither he had latterly retired, on the 6th of October 1612, in the seventy-fifth year of his age. Guarini's claim to the character of a great poet must rest exclusively on his *Pastor*

Fido, which, with all its faults, contains innumerable redeeming beauties, and still maintains its place as an Italian classic. His style, though it wants the purity, sweetness, and elegance, which characterize that of Tasso, is full of rich and sparkling imagery; and his sentiments, if not always natural or just, are seldom deficient in force and vivacity. The greatest blemish of the *Pastor Fido* is its frequent indecency and exceptionable morality. It is no doubt true that Corisco repents towards the conclusion of the piece, and that there is an apparent conformity in this respect to the established rule; but this professed repentance comes only after having displayed a character equally vile and perfidious, and promulgated maxims of the most lax morality. Although the *Pastor Fido* had been represented in all the courts of Italy, and even before popes, yet it was afterwards put into the *Index* by reason of the licentiousness which pervades it, and particularly on account of the passage commencing *Se'l peccar è si dolce e il non peccar si necessario.* But, with all these defects, it is a work of undoubted genius, and will continue to maintain the reputation which it originally acquired for its author. An excellent translation of the *Pastor Fido* into English blank verse was published anonymously at Edinburgh in 1809. (J. B—E.)

GUASTALLA, a walled town of Northern Italy, duchy of Modena, capital of a small district of the same name, on the right bank of the Po, 16 miles N. of Reggio. It is the see of a bishop, and has a cathedral and several other churches, and a public library. Manufactures—chiefly silk fabrics and twist. The French defeated the Imperialists under its walls in 1734. Pop. 10,000. The district of Guastalla formerly belonged to Parma, but since the death of the ex-empress Maria Louisa it has been transferred to Modena.

GUATIMALA, or GUATEMALA, one of the republics of Central America, occupies most of the table-land of Guatimala, with the mountainous district between it and the Gulf of Honduras, besides a portion of the table-land of Yucatan. Its extreme latitudes are 13. 29. and 18. 12. N., and longitudes 88. 10. and 93. 22. W. It is bounded on the N. by the Mexican state of Yucatan, on the W. by Chiapa, on the S. by the Pacific Ocean, S.E. by the Republic of Salvador, E. by Honduras, and N.E. by the Gulf of Honduras, and the British Honduras, or Belize. The total area of Guatimala is about 49,000 square miles. It is divided into seventeen departments, and contained, according to the returns of 1852, a population of 972,000, distributed as follows:—

Departments.	Populations.	Departments.	Populations.
Guatimala	89,500	Totonicapán	84,700
Sacatepec	44,500	Gueguetenango	64,800
Chimaltenango	56,400	Quesaltenango	66,800
Sanmarco	89,100	Chiquimula	73,000
Suchiltepec	36,300	Vera Paz	6,200
Escuintla	15,300	Salamá	109,900
Amatitlan	33,000	Isabel	9,000
Santa Rosa	36,000		
Mita	72,300	Total	972,000
Solola	84,200		

The surface of Guatimala is wholly mountainous, the main chain of the continuation of the Andes traversing it from S.E. to N.W. at an inconsiderable distance from the Pacific shore, and branching off in various ramifications towards the Atlantic; forming many valleys, but inclosing few plains. Along the main chain occur numerous volcanoes, all near the Pacific. The culminating point of the surface is in N. Lat. 15. 30., between the towns of Totonicapán and Gueguetenango. The eastern border of the plateau descending to the Gulf of Honduras is cut by deep valleys, which extend to a great distance, and in some places advance to the very shores. The country lying to the W. and the N.W. of the Golfo Dulce is a low plain, while all between the plateau and the Bay of Honduras is a succession of ridges and valleys. In many places the shore is rocky, with rocky barriers lying off it.

Numerous streams drain this state. The most important are—the Lacantun, forming part of the Mexican boundary; the Motagua and the Polochic, which fall through the Dulce into the Bay of Honduras. The most important lakes are—the Dulce, advantageous for foreign trading vessels; the Amatitlan, 18 miles S.E. of Guatimala, is 9 miles by 3, of great depth, and is much resorted to as a bathing-place by the inhabitants of Guatimala, from February till April; near it there are several mineral and hot springs; the Atitlan, 80 miles N.W. of the city of Guatimala, is about 20 miles long by 9 broad, surrounded by lofty heights, including the volcano of Atitlan, and is remarkable for its very great depth, and being without outlet, though several small rivers enter it; the Paten, near the frontiers with Yucatan, and about 30 miles long, 9 broad.

The climate of the table-land is that of perennial spring, the thermometer scarcely varying throughout the year, and it resembles very much the climate of Valencia in Spain in almost every particular. In the northern part of the state, in what is called *Los Altos*, the highlands, the average is lower than any other part of the country. Snow sometimes falls in the vicinity of Quesaltenango, the capital of this department, but soon disappears, the thermometer seldom remaining at the freezing point for any considerable time. In the vicinity of the city of Guatimala, the range of the thermometer is from 55° to 80°, averaging about 72° of Fahr. Vera Paz, the north-eastern department of Guatimala, and embracing the coast below Yucatan to the Gulf of Dulce, is nearly ten degrees warmer. This coast from Belize downwards to Isabel and San Tome is hot and unhealthy. From May till October is the rainy season. Thunder prevails in June, and terrific storms from the S.W. sweep along the Pacific coast in August and September. Earthquakes are very frequent.

The soil is generally very fertile, producing excellent rice, and all the cereals in great variety and abundance. Agriculture, however, is in a very backward state from the want of enterprise and the ignorance of the people, as well as from the want of roads. As articles of commerce, the most important products are cochineal and indigo. Cotton, cacao, sugar, vanilla, tobacco, and coffee, are grown in considerable quantities. The table-land is almost destitute of trees and even bushes, except on the declivities of the hilly ranges which so extensively traverse it. Trees of very large size form extensive forests on the lower lands along the Pacific. These are a source of great natural wealth. Among the trees the most valuable are the cedar, mahogany, Brazil, Santa Maria, pimento, guaiacum, &c.; and abundance of medicinal plants are also found and turned to some account. The vegetation is luxurious and vigorous along the low tract by the Bay of Honduras. Sheep are reared in considerable numbers, especially over the northern districts, and their wool is used for native manufactures. The horse is small, hardy, and handsome; and mules are numerous, being the chief beasts of burden. Pigs and poultry are very abundant, and of excellent quality.

Salt is manufactured along the coast of the Pacific. Jasper, marble, and brimstone, are obtained in considerable quantity in the vicinity of some of the volcanoes. Lead is worked by the Indians in Totonicapán. The manufactures are mostly limited to those for domestic use. The cotton manufacture, once extensive, is now confined to the departments of Guatimala and Sacatepec. Coarse woollen cloth is now more manufactured, especially *gerga*, which is made into a peculiar black called *poncho*, in which much taste is displayed.

Besides cochineal already noticed, the most important exports are woods employed in cabinet work; sarsaparilla, vanilla, and other medicinal roots and plants; hides, sugar, coffee, and cotton, in small quantities. The imports consist chiefly of wines, fancy goods, earthenware, porcelain, cutlery, hardware, silk and linens, dry goods, and British cotton.

The inhabitants of Guatimala are a mixture of native Indians, Europeans, and Negroes. The natives of negro blood are principally along the N.E. coast, and in Amatitlan. With the exception of certain portions of the indigenous Indians, or northern portions of Guatimala, the people of this state are characterized by all the vices that degrade the inhabitants of Central America.

Guatimala received its name from the Mexican word *quauhtemali*, "a decayed wooden log," because the Mexican Indians who accompanied Alvarado found near the palace of the kings of Kachiquel an old worm-eaten tree, and gave this name to the capital. In the mouth of a Spaniard the pronunciation became *guatimala*. Others have derived the name from the Tzendale word *uhatezmalha*, "a water volcano," in allusion to the mountain on the skirts of which the city of Guatimala was built. Another still less probable etymology is that from *coctecmalan*, "milk-wood," a peculiar tree found only in the immediate vicinity of the original capital, where now stands the village of Tzacualpa. Still another is from the name of *Guitemal*, the first king of Guatimala, as Quiché was named from Namaquiche, and Nicaragua from the cacique of the same name.

The principal part of Guatimala was conquered in 1524 by Alvarado, who found above thirty different tribes in possession of the country, each governed by its own chief, and using distinct languages and customs. The Pipil Indians still speak the Aztec or Mexican language, and dwell on the Pacific shores. Besides this there are above twenty different dialects used in the republic; but many of these are so similar that one tribe with little difficulty understands another. According to a tradition related by the historian Juarros, the Toltec Indians, the most civilized and powerful of the tribes of Guatimala, came originally from Tula in Mexico. This emigration is said to have been undertaken by the direction of an oracle in consequence of the great increase of the population in the reign of Namaquiché (*i. e.*, "Quiché the Great"), the fifth king of the Toltecas. Namaquiché V. died during their wanderings, and was succeeded by his son Acjopil, from whom Kicab-Tanub, the contemporary of Montezuma II., was the fourteenth in succession who reigned in Utatlan, the capital of Quiché, which stood near the Lake Atitlan, and was so named in honour of Quiché the Great, who had died during their perilous and tedious wanderings southwards. None of the Spanish settlements were conquered with so little bloodshed as that of Guatimala; and this was mainly owing to the celebrated Dominican Las Casas, who accompanied the conquerors in their expedition into this territory. In 1524 Alvarado founded the city of Guatimala; and in 1542 a chancery and royal *audiencia* were established in this city, with authority over all the settlements and provinces from the southern boundary of Costa Rica to the northern limit of Chiapas. Hence this city became the residence of the governor and captain-general. Till his death in 1541 Alvarado had exercised authority over the Spanish settlements from their subjugation in 1524, during four years under Cortez, and subsequently by direct delegation from the Crown. In 1742 the bishopric of Guatimala, which was established in 1534, became metropolitan, and was invested with authority over the suffragan bishoprics of Nicaragua, Chiapas (and Comayagua in Honduras). At this time the kingdom of Guatimala consisted of the aggregate of the settlements and districts; and under the Spaniards it formed a captain-generalship independent of the other governments and viceroyalties of Spanish America. During the fifteenth and sixteenth centuries Guatimala was severely harassed by the Dutch and English privateers, and by the inroads of the Poyaise and Mosquito Indians, who freely permitted the English to settle along their coast, while they maintained an unrelenting struggle with the Spaniards. On the 21st September 1821 the country became an independent state, and united itself with the Republic of Mexico; but again, on 1st July 1823, it became a separate government, and eventually the confederation of the five states of Guatimala—Salvador, Honduras, Nicaragua, Costa Rica, with the territory of Mosquitia—was formed. In 1846, however, this confederation was dissolved; and Guatimala, as well as each of the rest, became independent. Of late, attempts have again been made to renew the confederation, but, owing to political jealousies, without any definite result. The country has long been kept in a state of constant agitation, industry has been neglected, civil wars have been rife, and every effort to improve the condition of the inhabitants has been frustrated. Under a united system of government this country would rise into one of incalculable importance and influence. It possesses all the elements of prosperity in the resources and advantages with which nature has so richly and profusely invested it.

According to the constitution of October 19, 1851, the executive is in the hands of a president, elected by a general assembly, composed of the legislative chamber, the Archbishop of Guatimala, the members of the supreme court of justice, and the members of the council of state. The legislative assembly consists of fifty-nine members; and the president is elected for four years, but is eligible to be re-elected. The council of state is composed of the ministry, eight councillors chosen by the legislative assembly, and of others appointed by the president. The revenue and expenditure are about L.50,000, and the debt now amounts to L.240,000.

The principal cities in this republic are New Guatimala, the capital; Old Guatimala, Totonicapau, Quesaltenango, Chiquimula, Salamá, Flores, &c.; and the chief ports are Isabel, or Golfo Dulce; San Tomé, on the Bay of Honduras; and Istapá, on the Pacific.

The antiquities of Central America have recently been partially investigated by travellers, and are beginning to yield some fruits. The most prolific of the states, as yet, is Guatimala, which is now (1856) being examined by a judicious and experienced antiquarian, the Abbé Brasseur de Bourbourg, who resides as *cura* at Rabinal in Vera Paz, one of the least known of the departments of Guatimala. He is there in direct relationship with the native Indians of that district, which has longest resisted the advances of European civilization, and in which the aborigines have probably retained most of their primitive traditions, customs, and religious ideas. Between Vera Paz, Yucatan, and Chiapas, there lies a wide tract of country, drained by the great river Usumasinta, and inhabited by the unconquered tribes of the Lacandones, Manches, Choles, &c., all belonging to the great Tzendal or Maya family, who built the now ruined temples of Yucatan, and reared Palenque and Copan. This region is full of extensive ruins and imposing monuments; and the Abbé Brasseur de Bourbourg is here earnestly prosecuting his researches under most favourable circumstances. His object is to reach the lake of Peten, or Itza, so well known from the early chronicles as the stronghold of the warlike Itzaecs. The islands of this lake are covered with ruins, of which imperfect accounts have been given to the public by Colonel Galindo. But so little is yet known of this country that it has not been ascertained by Europeans whether this large lake discharges itself north into the Gulf of Mexico, or east into the Bay of Honduras, or, indeed, if it have an outlet at all. The documents brought to light by the Abbé de Bourbourg must prove of great value in elucidating the aboriginal history of America. These consist of a copy of the *Kachiquel grammar del Padre Flores*, containing a comparison of the Kachiquel with the Quiché and Zutugil, "the three metropolitan languages," which are all dialects of a single stock; the original MS. of Ximenes, of which only a part is copied in that of Ordoñez; *The Ancient History of Quiché* in Spanish and Quiché; a MS. *History of Guatimala of Vera Paz*, in Spanish, with numerous details on the astronomy and religion of the natives. And beside these, a separate history of Vera Paz; another of San Salvador; and another of the rebellion of the Tzendals, with a magnificent copy of the *Tonalamatl*, or Calendar of the Indians of Quiché, as still secretly used by the Indians of Santa Catalina Ixtahuacan, have been obtained by this indefatigable Abbé. But the most precious of his acquisitions is a MS. in the Kachiquel language, written about 1550 A.D., by one of the princes of Sololá, near the Lake of Atitlan; this he is rendering into French and Spanish; and it is full of details of the immigration of the Indians into these countries, their early sufferings, the valorous conduct of their chiefs, of the four Tulas that existed, &c. The abbé has visited two ancient cities full of large ruins; they are called Zamaneb or Cakyug, and Tzak-Pokomá. These he discovered by means of a *bayle* or dramatic dance, recited to him by a native Indian, a descendant of the ancient chiefs of Vera Paz. The facts of this *bayle* agrees with Ximenes, and also with the Kachiquel MS. already mentioned.

The best writers on Guatimala are,—Bernal Diaz del Castillo, *Historia Verdadera de la Conquista de Mexico*, 1632; Herrera, *Historia General de los Hechos de los Castellanos en los Islas y Tierra*

Ferme del Mar Oceano, Madrid, 1601; Alcedo's *Geographical Dictionary of Spanish America*, by —— Thompson, London, 1810, but at Madrid, 1786–89; Haefkin, *Centraal Amerika;* Juarros, *Guatimala*, which garbles the facts preserved in the MS. of Ximenes; Humboldt's, Thompson's, Byam's, and Dunn's Travels; Baily's *Central America*, which is accompanied with a good map, and is the most recent and reliable source of information up to this time (1856).

GUATIMALA, *la Antigua*, a city of Central America, in the republican state of Guatimala, and about 27 miles W.S.W. from Guatimala la Nueva. It stands in a wide and fertile valley, at an elevation of 5820 feet above the sea-level. The place was abandoned after the earthquake of 1773, which partially destroyed it; but it now contains a population of nearly 20,000. There is collected here a considerable quantity of cochineal; and there are some insignificant manufactories. The city is regularly laid out, but a great part of it is still in ruins. Prior to the earthquake the population amounted to about 60,000.

GUATIMALA, *la Nueva*, the capital of the republic of Guatimala, in Central America.[1] Its situation is in N. Lat. 14. 36., and W. Long. 90. 30., at the extremity of a plain 22 miles in length by 7 in breadth, with a deep ravine on three sides, and elevated above the sea 4970 feet. The form of the town is quadrangular; and the streets are wide, straight, and clean. On account of the frequency of earthquakes the houses are only one story in height. The Plaza or Great Square measures about 150 yards on each side, and is surrounded on three sides by colonnades. Here are the principal buildings in the town—the cathedral, archbishop's palace, the old royal palace, the *College de Infantes*, and the various government offices. In the centre stands a large and elegant fountain. The town is well supplied with water brought by pipes from the mountains upwards of two leagues distant. Besides the cathedral, there are 26 other churches and chapels; and, besides the plaza, several other squares, each with a fountain in the centre. At the south side of the city there has recently been erected a fort mounting 20 guns. There are several private schools in Guatimala; and several printing establishments, whence two weekly newspapers are issued.

Thompson, in his *Official Visit to Guatimala*, states that "the mean heat" of the city of Guatimala "during the day, from the 1st of January to the 1st of July is 75° of Fahr., at night 63°. In the summer months the average may be taken at ten degrees higher." Fruits, vegetables, provisions, and all articles of ordinary consumption are abundant, at moderate prices, while many descriptions of British manufacture are as cheap as in Britain. The manufactures are muslins, gauze, cottons, earthenware, porcelain, jewellery, cigars, &c.

The inhabitants are courteous and hospitable to strangers, but live very much apart from each other, their only recreation being their incessant religious processions. The suburbs are occupied mostly by ladinos (mulattoes) and Indians. The buildings of this city were begun in 1776, three years after the fearful earthquake of 1773, which completely destroyed Old Guatimala, the former capital. The population is variously estimated from 35,000 to 50,000.

GUAVA, the fruit of the *Psidium pyriferum* and *P. pomiferum*, nat. ord. Myrtaceæ, the pulp of which is made into a jelly of a peculiarly delicious flavour. This sweetmeat is imported in considerable quantities from the West Indies.

GUAYAQUIL, the name of a department, province, city, river, and gulf, in the republic of Ecuador, South America. The department is bounded on the west by the Pacific, and on the other sides by Peru and the departments of Ecuador or Quito and Assuay. The great chain of the Andes forms its eastern boundary. The chief products are cacao, cotton, maize, tobacco, and various kinds of fruits. Area, 26,238 square miles. Pop. estimated at 132,000. It is divided into the provinces of Guayaquil and Manabi, the capitals of which are Guayaquil and Puerto Viejo. Guayaquil, the capital of the above department, and the chief commercial town of the republic, stands on the right bank of the river of the same name, which is here about 2 miles wide, in S. Lat. 2. 12., W. Long. 79. 39. It extends about 2 miles along the river, and is divided into an old and new town; the former stands higher up the river, and is entirely inhabited by the poorer classes. Guayaquil is very unhealthy, which may be sufficiently accounted for from its low, level site, without drainage, the marsh immediately behind it, and the effluvia arising, especially in hot weather, from the mud left exposed to the action of the sun by the receding tide. There is also a deficiency of fresh water, the river being brackish for a considerable distance above the town. None of the public buildings are remarkable for architectural beauty; and the houses are generally of only one story, and built of wood. Vessels of considerable burden can come up to the town, as the tide at full and change rises 24 feet. Foreign goods are imported in considerable quantities, and sent up the river in balzas to Babayhoyo or Caracol, whence they are carried on the backs of mules to the valleys of Ambato and Quito; and almost all the native products exported are sent from this port. It has a dry dock; and several vessels of a superior construction have been built here. Cacao is the principal article of export, and next to it are straw-hats, hides, timber, tobacco, bark, &c. The chief articles of import are British manufactured cottons and hardware, silks, wine, flour, &c. In 1851, 181 vessels, of 16,051 tons entered and cleared at the port; the cargoes in the former case were valued at L.274,700, in the latter at L.287,800. Guayaquil is subject to frequent and terrific earthquakes. Pop. about 28,000. The Guayaquil River is the principal in Western Ecuador. It is formed by the union of numerous streams from the Andes, and becomes navigable for commercial purposes at Babayhoyo or Caracol, 70 or 80 miles from its mouth—river boats ascending to one or other of these places according to the season. Below Guayaquil the channel is impeded by numerous rocks and small islands, while at its mouth is the larger island of Pana. Where the river falls into the Pacific it is known as the Gulf of Guayaquil, the extreme points of which are 70 miles apart.

GUAYMAS, a seaport-town of Mexico. See MEXICO.

GUAYRA, LA, the principal seaport-town of the republic of Venezuela, province of, and 11 miles N.N.W. of Caracas. It is in an unhealthy situation, and is closely surrounded by high mountains and rocks. The chain of mountains which separates it from the high valley of Caracas descends almost directly into the sea; and the houses of the town are backed by a wall of steep rocks, leaving scarcely 100 or 140 fathoms' breadth of flat ground between this wall and the sea. The town is poorly built, and contains no edifice worthy of notice. The port is unsheltered, but has good anchorage in from 6 to 30 fathoms, and is well defended by land batteries. Its chief exports are coffee, cocoa, indigo, and hides, with some cotton and sugar. Pop. about 8000.

GUBBIO, or EUGUBIO (the ancient *Iguvium*), a city of the Papal States, delegation of Urbino, and 27 miles S. of the town of that name. It is pleasantly situated at the foot of the Apennines, and is well built. Among its fine edifices are the ducal palace, cathedral, and several churches. Gubbio, however, derives its chief interest from the celebrated Eugubian tables which were found near this, in

---

[1] A city of this name was founded by Don Pedro de Alvarado in 1524, about 27 miles W. of the present city, near the town of Guatimala la Antigua, and was destroyed in 1541 by enormous masses of water bursting forth from the neighbouring volcano which was henceforth called Volcano de Agua.

1444, among the ruins of an ancient temple, and are now preserved at Gubbio. (See Eugubian Tables.) Pop. 8000.

GUBEN, a walled town of Prussia, capital of a cognominal circle in the government of Frankfurt, and province of Brandenburg, on the Neisse, which is here navigable, and on the Berlin-Breslau railway, 27 miles S.S.E. of Frankfurt. It is the seat of the courts of justice for the circle, and of a board of horticulture; and has a gymnasium, a public library, and manufactures of woollen cloth, linen, hosiery, leather, &c. It carries on a considerable trade in cattle, wool, and agricultural produce. Pop. (1849) 11,448.

GUDGEON, in *Mechanics*, the pin inserted in the end a horizontal shaft for its support, and on which it turns.

Gudgeon, a species of cyprinus. See Ichthyology.

GUEBRES, Guebers, Gaurs, or Gavres (*i.e.*, "giaour," or infidel), terms used in the East to designate the Fire-worshippers, a very ancient religious sect in Persia, who derive their origin from the immediate followers of Zoroaster. In India, where a colony of this sect has long been established along the western coast, they are called *Parsees*, a name indicative of their origin. Many of these have acquired great wealth and distinction, particularly at Bombay. The characteristic feature in this religion is the worship of fire, which the *Behendie* (*i. e.*, "followers of the true faith"), as they designate themselves, profess to regard as symbolical of the Supreme Power, which, as imaged in the sun, quickens, vivifies, and blesses all things; or, in other words, as the emblem of Deity. Their sacred books are termed the Zend-Avesta, the authorship of which is ascribed to Zoroaster, though it is unquestionably a spurious production. For an exposition of the leading tenets of this sect, see Zend.

The Fire-worshippers of Persia at the present day are nearly confined to the city of Yezd, and some towns in Kerman. They are a mild and inoffensive race, industrious, and temperate. They drink wine, eat all kinds of meat, and eschew polygamy, which is specially prohibited by their religion, except in cases of hopeless sterility, when a second wife is admissible. They have a singular mode of disposing of their dead, by exposing the bodies upon the towers of their temples, to be devoured by birds; and, from observation of the part first preyed upon, they draw inferences as to the fate of the deceased.

GUELDERLAND, or Gelderland, a province of Holland, lying between N. Lat. 51. 45. and 52. 32., and E. Long. 4. 57. and 6. 47.; and bounded on the N.W. by the Zuider-Zee, N.E. by the province of Overyssel, E. by the Rhenish provinces of Prussia, S. by Limburg and North Brabant, and W. by South Holland and Utrecht. It is 88 miles in length from E. to W., and its greatest breadth is 54 miles. Area, 1962 square miles. The surface is generally level, but not so flat as in most of the other provinces of Holland, and some parts of it might even be said to be hilly. The soil in the cultivated parts is good, but a considerable portion of it is either sandy down or covered with heath. The principal crops are wheat, rye, potatoes, hops, and tobacco. The pasturage is excellent, and orchards are very numerous. The principal rivers are the Rhine, the Waal, the Yssel, the Leck, and the Maas, besides which there are several smaller rivers and canals. It is traversed by the railway from Amsterdam to Arnheim. The inhabitants are chiefly employed in agriculture, but some manufactures are also extensively carried on, as of leather, paper, and linen. The province is divided into four arrondissements—Arnheim, Nimeguen or Nijmegen, Zutphen, and Thiel. The capital is Arnheim. Pop. (1854) 390,512.

GUELDERS, or Geldern, a town of Rhenish Prussia, government of Düsseldorf, on the Niers, 26 miles N.W. of Düsseldorf. Pop. 3974. It was the capital of the old duchy of Guelders, which subsequently formed part of the duchy of Burgundy; and by the peace of Utrecht one part was ceded to the republic of the Netherlands and the other to Prussia.

GUELPH, Order of, or Royal Guelphic Order, a Hanoverian order of knighthood, founded in 1815 by the Prince Regent, afterwards George IV. It consists of grand crosses, commanders, and knights; and is both a civil and a military distinction. It is sometimes styled colloquially the "*Order of Merit.*"

GUELPHS, or Guelfs, the designation of a powerful party in the middle ages, which, in Germany, and at a later period in Italy, opposed the German emperors and their adherents, who were called Ghibelins. The wars of the Guelfs and Ghibelins became the struggle between the spiritual and secular power—the Guelphs standing for the Pope, and the Ghibelins for the Emperor. These factions filled Italy with bloodshed for nearly 300 years.

The rise of the Guelphs is referred by some to the time of Conrad III. in the twelfth century; by others to that of Frederick II.; and by others, again, to that of his successor, Frederick III., in the thirteenth century. The name of *Guelph* is commonly said to have been formed from *Welfe*, or *Welfo*. The Emperor Conrad III. having taken the duchy of Bavaria from Welfe VI., brother of Henry, Duke of Bavaria, Welfe, assisted by the forces of Roger king of Sicily, made war on Conrad, and thus gave birth to the faction of the Guelphs. Some derive the name *Guelfs* from the German *Wolff*; and others deduce it from the name of a German called *Guelfe*, who lived at Pistoia; adding, that his brother, named *Gibel* or *Ghibel*, gave his name to the Ghibelins. See Ghibelins.

GUERANDE, a town of France, department of Loire Inférieure, arrondissement of Savenay, about 3 miles from the sea, 23 miles W. of Savenay. It occupies the slope of a hill, is surrounded by walls, and commanded by an old castle. The chief manufactures are woollen and cotton stuffs; and large quantities of salt are procured from salt marshes in the vicinity. Pop. 8550.

GUERCINO. See Barbieri.

GUERICKE, Otto Von, a highly distinguished experimental philosopher, was born at Magdeburg in 1602; died at Hamburg in 1686. It is to him that we owe the first construction of the air-pump, afterwards improved by Boyle. (See Pneumatics.) He was also the first to prove the force of the pressure of the atmosphere, by applying to each other two hemispheres of brass, from which he exhausted the air, and which sixteen horses were unable to pull asunder. These experiments are all detailed under Pneumatics. Guericke's observations on these subjects, and also on astronomy, which he had studied with care and success, were published under the title of *Experimenta Nova, ut vocat. Magdeburgica, &c.*, Amsterdam, 1672.

Guericke's personal character seems to have been a highly amiable one. He was held in high esteem by his fellow-citizens, who elected him burgomaster. He was also honoured with the title of Counsellor to the Elector of Brandenburg.

GUERNSEY, one of the islands in the English Channel, belonging to Britain, and lying between N. Lat. 49. 24. and 49. 33., W. Long. 2. 32. and 2. 48. It is situated in the Bay of St Michael, 30 miles W. of the coast of Normandy, 52 miles S. of Portland, the nearest point of land to England, and 15 miles W.N.W. of Jersey. It is of a triangular form, is 9 miles in length, by from 3 to 4 in extreme breadth, and has an area of about 16,000 acres. The northern part of the island is a low level tract, but towards the S. the land becomes more elevated and hilly, with deep and narrow valleys and glens intervening. It has about 30 miles of coast deeply indented with commodious bays and harbours; on the N. side low and flat, on the S. bold and precipitous. Off the coast are numerous sunken rocks and crags, which, together with the rapid currents among them, causing the tides frequently to rise to the height of 32 feet, render the approach extremely hazardous to strangers. The geological formation of the island is almost entirely granite, the prevailing rocks being gneiss, granite, and sienite. These are extensively quarried in several parts, and are sent in large quantities to Portsmouth, London, and other places. Some trap-rocks and micaceous schist occur on the western side of the island. It is tolerably well watered with springs and clear gravelly streams. The climate, though moist and subject to sudden changes, is not unhealthy. The winters are mild; and the summers, though hot, are less oppressive than on the neighbouring coast of France, or even than in the S.W. of England. Snow is rare, and the frosts are neither severe nor continuous. The mean winter temperature is about 41° 62′, that of summer 60° 7′. The thermometer seldom rises above 80°, or falls below 37°. Easterly winds prevail during spring, and westerly during the rest of the year. Guernsey is not equal in fertility to Jersey, neither is it so well wooded; but fruit-trees are numerous, especially the fig and apple. From the fruit of the latter much cider is made. Agricultural improvement is much retarded by the very small size of the farms, arising from the custom of each son sharing equally in his father's landed property. Few of them are exclusively devoted to agriculture, but generally carry on also some other profession or trade. Farms most generally vary in size from 5 to 12 acres, and very few of them exceed 30. The chief of the agricultural productions are wheat, barley, potatoes, and parsnips. Sea-weed is the principal manure in use. Oranges, melons, and other fruits, which in England require shelter, grow here in the open air. Flowers are also extensively cultivated, among which is the Guernsey lily. The people devote their attention greatly to the rearing of cattle and the dairy. The cows are much esteemed, and the butter is excellent. The native breed of horses is poor, but it has been much improved of late years. Hogs are numerous, and of great size, but few sheep are reared or fattened. Guernsey is divided into ten parishes, and its chief town is *St Peter Port*. The trade of Guernsey is very inferior to that of Jersey, and has greatly decreased since 1807, when it was made subject to our revenue laws, previous to which time its trade had chiefly consisted in smuggling. Steamers ply between Guernsey and London, Southampton, Plymouth, and Weymouth. The imports are British manufactures, wheat, flour, wines, sugar, coffee, &c.; exports—cider, apples, potatoes, cattle, granite, and wine. Guernsey and the rest of the Channel Islands came to England with the duchy of Normandy, and are now all that remain to the English Crown of that possession. The inhabitants are simple and thrifty in their habits, and still retain many of their ancient customs. Their language is the Norman French of some centuries ago, though English is very generally understood among the upper classes. The government of the island is vested in the hands of the states, composed of the bailiff, the procureur or attorney of the royal court, twelve jurats, eight rectors of parishes, and the constables of parishes, one from each of the country parishes, and six from the town parish—in all thirty-seven. The bailiff and procureur are nominated by the crown, the rectors by the governor, while the constables are chosen by the inhabitants. The "Royal Court," the supreme court of justice, consists of a bailiff appointed by the crown, and twelve jurats elected by the people. Guernsey, with Alderney and its other dependencies, in 1851 had 64 places of worship, of which 16 belonged to the Church of England, 7 to Independents, 6 to Baptists, 26 to various classes of Methodists, 2 to Roman Catholics, and the rest to minor bodies. The total number of sittings was 23,827. There were 115 day schools, of which 28, with 2477 scholars, were public, and 87, with 1994 scholars, private; and 33 Sunday schools, with 4315 scholars. Pop. (1851) of Guernsey, 29,757; of adjacent islands, 3962.

GUESCLIN, Bertrand du, Count of Longueville, constable of France under Charles V., was born at the castle of Lamotte-Broon, near Rennes in Brittany. His birth, the exact date of which is not known, is variously assigned to the years 1314, 1318, and 1320. At the proper age he was put under the care of a tutor; but he had little taste for learning, and it was found impossible to teach him either to read or write. But in all manly games and exercises he displayed a most precocious dexterity; and at the tournament given at Rennes in 1338, on the occasion of the marriage of Jeanne-la-Boiteuse with Charles of Blois, he was eleven times victorious, and gained the great prize of the day, which he presented to the friend who had lent him the arms and horses he had fought with. He grew up strong and tall, but ill-made, and, as he himself said, so ugly, that he knew he would never please the ladies; "but," he added, "I shall make myself dreaded by the enemies of my king." Entering on the military career, he distinguished himself by many deeds of chivalrous daring against the English, who had at that time overrun the fairest provinces of France; and when the battle of Poitiers threw King John into the hands of Edward of England, he alone upheld the fortunes of his country, and checked in many places the victorious progress of the foe. Du Guesclin's next great exploit was the defeat of the allied forces of England and Navarre at the famous battle of Cocherel, on the banks of the Eure. For this achievement, which established Charles V. on the throne, Du Guesclin was made Comte de Longueville and Maréchal de Normandie. His usual good fortune, however, was clouded towards the close of this same year (1364), by a sad disaster. At the battle of Auray in Brittany, he was taken prisoner by the English under the redoubtable Sir John Chandos. After peace was restored between France and England, Du Guesclin, who had been ransomed for 100,000 crowns, was once more free to serve his country. An opportunity was not long wanting. A great number of French and English adventurers whom the peace had thrown out of employment had joined their forces, and under the title of *Les grandes Compagnies*, were laying waste the richest provinces of France. Du Guesclin, who had been commissioned by Charles V. to get rid of them either by violent or by gentle means, induced them to take service with him against the Moors, whom he professed himself anxious to drive out of Spain. His real motive, however, was to help Henry of Transtamare, who was then at issue with his brother Peter the Cruel for the throne of Castille. As the "compagnies" were passing Avignon, they demanded from the Pope, then living there, a reversal of the sentence of excommunication, formerly pronounced against them, and a black-mail of 200,000 florins. The Pope refused to grant either request; but when he saw the "compagnies" laying waste the country, and carrying their devastations into Avignon itself, he gave them his blessing and half the required amount of gold. Du Guesclin, without difficulty, placed his friend, Henry of Transtamare, on the throne of Castille; but the dethroned Don Pedro invoking the assistance of the Black Prince, once more took the field, and in the engagement which followed, Du Guesclin's army was annihilated. Seeing resistance useless, he surrendered to his noble captor, saying, "J'ai du moins la gloire de ne remettre mon épée qu' au plus vaillant prince de la terre." When the subject of his ransom was mentioned, "I am but a poor knight," said Du Guesclin. "Then I shall only ask you for a hundred francs, or less, if you choose," said the chivalrous Englishman. Du Guesclin, however, declining to rate himself so meanly, offered 100,000 gold florins. "It is too much," said the Black Prince, "and if it be true that you are a poor knight, whence will you get the means?" "The kings of France and Castille are my friends," said he, "and will not allow me to want for anything; and there are, besides, a hundred Breton chevaliers who would sell their lands to make up the sum." He was no sooner free than he took the field again in the interest of Henry, routed and slew Don Pedro; and after many bloody encounters with the Moors, seated his friend securely on the Castillian throne. His last exploit in the service of France was to drive back the English from the walls of Paris, which they had threatened; and he afterwards re-annexed to the French crown many places that had long groaned under the English yoke. He failed, however, in some enterprises in Brittany; and his enemies having maligned him to the king—who was foolish enough for a moment to doubt the honour of the warrior who had saved France and his throne—Du Guesclin, stung by the affront, resolved to quit his country and seek an asylum with his friend Henry of Castille. On his way into exile, he found his old brother-in-arms, Saucerre, engaged in the siege of Randam. The governor of the town, reduced to the last extremity, offered to surrender, if he were not relieved within fifteen days. In this interval Du Guesclin fell sick and died (July 13, 1380), and the next day the governor of Randam, marching out of the town at the head of his garrison, laid the keys of the gate on the breast of the dead knight.

The name of Du Guesclin is still held in veneration by the French. His bravery, his gentleness, his generosity, and his modesty, have all contributed to make him one of the most popular heroes of France. His name is generally associated with that of Bayard, as the two last examples of all knightly virtues and accomplishments.

GUIANA, GUYANA, or GUAYANA, an extensive territory in the north-eastern part of South America, comprehending in its widest acceptation all that extent of country lying between the rivers Amazon and Orinoco, between Lat. 3. 30. S., and 8. 40. N., and Long. 50. 22., and 68. 10. W. It is bounded on the N. by the Orinoco and the Atlantic, E. by the Atlantic, S. by the Amazon and the Rio Negro, and W. by the Orinoco and the Cassiquiare. Its greatest length from E. to W. is about 1200 miles, and its greatest breadth about 850 miles; estimated area 700,000 square miles. This vast territory is divided into Brazilian (formerly Portuguese) Guiana, Venezuelan (formerly Spanish) Guiana, and Colonial Guiana. The two former, comprising about five-sixths of the entire region, are now included within the limits of their respective countries; while Colonial Guiana is that to which the general term of Guiana is now commonly applied. It is subdivided into British, Dutch, and French Guiana.

GUIANA, *British*, the most westerly of the three colonies, is bounded on the N. and N.E. by the Atlantic, E. by Dutch Guiana, from which it is separated by the River Corentyn, S. by Brazil, and W. by Venezuela. It lies between N. Lat. 0. 40. and 8. 40., and W. Long. 57. and 61., and has an estimated area of 76,000 square miles; but the possession of much of this has been disputed by Brazil and Venezuela. It is divided into three counties, Demerara, Essequibo, and Berbice, so named from the three principal rivers which drain them. Demerara, situated between the other two, occupies the centre of the seaboard for nearly 90 miles. To the N.W. the county of Essequibo stretches along the coast towards the swamps and forests of the western frontier; and to the S.E. lies the county of Berbice.

The entire coast of British Guiana is low, and generally bordered with a sandy flat extending far out to sea, so that vessels drawing more than 12 feet of water cannot approach within 2 or 3 miles of land. The rivers, too, deposit at their mouths large quantities of mud and sand, and are thus inaccessible to vessels of large size. Extending from low-water mark to a distance of 5 or 6 miles inland, is a tract of rich alluvial soil of recent formation. This is succeeded by a flat narrow reef of sand running exactly parallel with the present line of coast. Here remains of stranded vessels and anchors eaten through with rust have been found, indicating that within a comparatively recent period it had been washed by the waves of the Atlantic. Running parallel to this reef, at irregular distances, varying from 10 to 20 miles, is a second and higher range, composed of coarse white sand; and which at a period more remote probably formed the sea-limit. In the wet seasons the intermediate tract between these two reefs becomes the bed of extensive savannahs; for the creeks being then unable to carry off the torrents of rain which fall, overflow their level banks, and inundate the surrounding country to the depth of 5 or 6 feet. On the return of dry weather the waters gradually subside, leaving behind them a thick layer of decayed grasses and aquatic plants which had floated and flourished on their surface, and these in time produce a vegetable mould of considerable thickness. Beyond the second reef are swampy plains, intersected by sand-reefs, and extending to the mountainous regions of the interior. The high land does not rise immediately from the plain to a great elevation, but begins with a range of sand hills of from 50 to 200 feet above the plain. Behind these the high land stretches out in level or undulating plains, rising here and there into eminences. About N. Lat. 5., a mountain chain, an off-set of the Orinoco Mountains, and composed of granite, gneiss, and other primitive rocks, runs from W. to E. through this territory, forming large cataracts where it is crossed by the rivers, and rising frequently to the height of 1000 feet above the sea. About a degree farther south is the Pacaraima chain, which, in like manner, runs from W. to E., and is of primitive formation. Its highest point, called by the natives Roraima, in N. Lat. 5. 9. 30., W. Long. 60. 47., is 7500 feet above the level of the sea. The plains south of this range are in general level, and form extensive savannahs, covered with grasses and plants. The Sierra Acarai is a densely-wooded chain of mountains, forming the southern boundary of Guiana, and the watershed between the basins of the Amazon and the Essequibo. This chain rises to the height of 4000 feet. The Conocou or Cannucu Mountains, running S.E. and N.W., connect the Pacaraima with the Sierra Acarai.

The principal river of British Guiana is the Essequibo, which rises in the Sierra Acarai, and after a course of at least 600 miles, discharges itself into the ocean by an estuary 20 miles in width, in N. Lat. 7., W. Long. 58. 40. In the estuary of the Essequibo are a group of beautiful islands partially cultivated, the principal of which are Varken or Hog Island, about 21 miles in length by 3 in breadth, Wakenaam and Leguan, each about 12 miles by 3, and Tiger Island, about half that size. The entrance is difficult and dangerous, even for vessels of small size, on account of the banks of mud and sand. Its course lies through forests of the most gigantic vegetation. In N. Lat. 3. 14. 35., it forms a great cataract, named by Schomburgk, King William's Cataract. In N. Lat. 3. 57. 30., and W. Long. 58. 3., it receives the Rupunoony, which has a course of about 220 miles. At various points of its course it forms rapids and cataracts which impede its navigation. About 60 miles from its mouth occur the last of these, the Falls of Etabally, after which it pursues its course through the low alluvial plain. In this part of its course it receives the united waters of the Cuyuni and the Massaroony. The Demerara or Demerary rises probably near N. Lat. 5., and after a northward course, nearly parallel with the Essequibo, of more than 200 miles, it enters the Atlantic near N. Lat. 6. 50., W. Long. 58. 20. It is navigable for 85 miles, and at its mouth at Georgetown it is more than a mile and a half across. Farther east runs the Berbice, whose source is probably about N. Lat. 3. 40. It joins the Atlantic by an estuary 5 miles in width, 10 miles N. of New Amsterdam, and in

N. Lat. 6. 21., W. Long. 57. 12. It is navigable for 165 miles from the sea, by vessels drawing 7 feet water. The Corentyn which forms the eastern boundary of British Guiana, and probably has its source in the Sierra Acarai, flows generally northward and falls into the Atlantic in N. Lat. 6., W. Long. 57. It is navigable for boats for 150 miles. The mineral productions of Guiana are necessarily but imperfectly known. Clays of various kinds, including excellent pipe-clay, are found near the coast. The chief rocks are granite, porphyry, gneiss, clay-slate, sandstone, &c. Traces of iron are found in various parts; and gold has been recently (in 1852) discovered in considerable quantities on the Upper Essequibo.

The climate of Guiana is more healthy than that of most places in the West Indies. Its salubrity has been much increased since the occupation of the country by Europeans, the gradual clearing and cultivation of the surface having done much to mitigate those diseases so fatal in a low, marshy, and hot region. The hurricanes so destructive in the West Indies are unknown here, and gales are unfrequent. Thunder-storms occur only during the rainy seasons, but like the few occasional shocks of earthquakes, are not attended with danger. The year is divided into two wet and two dry seasons. The long rainy season sets in about the middle of April, when light showers begin to fall. The rain increases till the middle of June, when it falls in torrents; in the beginning of July these heavy rains begin to decrease; and in August the long dry season begins, and continues till November. December and January constitute the short rainy season, and February and March the short dry season. The winds during the rains are generally westerly; in the dry season they blow mostly from the ocean, loaded with moisture, and thus render the heat less oppressive than it would otherwise be. The thermometer seldom rises above 90°, and rarely falls below 75° Fahr. The mean annual temperature at Georgetown is 81° 2′; the total annual fall of rain averages about 100 inches.

The vegetation of Guiana is most luxuriant. The interior is thickly wooded with valuable timber, with the exception of the swamps of Berbice and the savannahs. The trees are of great size, and many of them are valuable for their timber or their fruits, or as dyewoods. Medicinal plants, including quassia, gentian, the castor-oil plant, and many others, are abundant. Arnotto, so extensively used in the colouring of cheese, grows wild in profusion on the banks of the Upper Corentyn. That largest of the water lilies, the *Victoria Regia*, was first discovered here by Mr Schomburgk on the banks of the Berbice. The *hai-arry*, an indigenous plant deserving of notice, is a papilionaceous vine, the root of which contains a powerful narcotic, and is commonly used by the Indians in poisoning the waters to take the fish, which are not thereby deteriorated.

The domestic animals are the same as those in England, and the wild animals are those common to tropical South America generally. Black cattle here attain a larger size than in Europe, but their flesh is not so tender nor so fine flavoured. The wool of the sheep is converted into hair. Game, chiefly deer, range the upper savannahs. Tigers, little inferior in size to those of Asia, but different in character, being rarely known to attack man, abound; as do also jaguars, which prey upon the herds of wild cattle and horses that graze on the extensive plains among the mountains. Among the other animals are the tapir, armadillo, agouti, ant-bear, sloth, and a great variety of monkeys. Lizards, snakes, and alligators are numerous. There are several kinds of parrots, mackaws, and humming-birds; also the flamingo, Muscovy duck, toucan, spoonbill, and vampire bat. Troublesome insects are numerous, as might be expected from the swampy nature of the coast districts. The rivers and coast abound with a great variety of fish.

The cultivated portion of British Guiana is merely a narrow strip along the sea-coast, and for a few miles up the rivers, including a portion of the islands of Essequibo. The whole surface of the coast lands being on a level with high-water mark, when these lands are drained and cultivated they consolidate and become fully a foot below it, so that the estates require to be protected from inundation by dams and sluices. Each estate has therefore a strong dam or embankment in front; while a similar erection at the back or inland boundary, as well as on each side, is requisite to keep off the immense body of water accumulated on the savannahs during the wet seasons, and which, if not repelled, would rush down to the sea, carrying everything before it. The state of his dams, therefore, requires the planter's unremitting attention; not the slightest hole or leakage is allowed to exist in them, and by law their wilful injury is considered felony. One inundation destroys a sugar estate for eighteen months, and a coffee one for six years. "The original cost of damming and cultivating is fully paid by the first crop, and the duration of the crops is from 30 to 50 years; so that though great capital is required for the first outlay, the comparative expense of cultivation is a mere trifle compared with that of the West India Islands, notwithstanding that the expense of works, buildings, and machinery may be treble or quadruple, being built on an adequate scale for half a century of certain production." (*Geog. Jour.*, vol. iv., 323.) Inside and at the foot of these dams are trenches 12 to 18 feet wide, and 5 feet deep, running round the whole plantation, and into these, smaller trenches and open drains convey the water that falls upon the land. These large trenches discharge their contents into the sea through one or more sluices, which are opened as the tide ebbs, and shut against the returning flood.

The staple productions of the colony are sugar, coffee, and cotton. From an official table of the exports of British Guiana from 1826 to 1851, we find that in 1827, 15,904 bales of cotton were exported; but from that period this cultivation gradually gave place to sugar, and in 1844 ceases to appear in the table as an article of export. Since 1851, however, it seems to have received more attention, for among the exports from British Guiana into the United Kingdom in 1854, we find 1093 cwt. of cotton. Coffee, from upwards of 9,500,000 lbs. in 1830, gradually fell off to only 3198 lbs. in 1851. As to sugar, making a due allowance for the difference of seasons, the quantity exported remained pretty steady from 1826 to 1837, the year preceding the termination of the apprenticeships,—averaging about 66,000 hogsheads; but in the year following that event it fell down to nearly half its former average, being in 1839 only 3827 hhds. In 1846 it had sunk as low as 26,201 hhds., owing in a great measure to a protracted drought through a great part of that season. In 1851, 43,034 hhds. were exported. In proportion to the sugar obtained the quantity of molasses is large, owing partly to the defects of the common process of preparation, but chiefly to the fact that the soil is so rich an alluvium, and so abundant in alkaline and earthy saline matter. Little of the molasses is boiled down into sugar in the colony; it is chiefly made into rum, or sold to the refiners, by whom it is much prized. In 1851 the quantity of molasses exported was 9530 puncheons. Although the rum produced in this colony does not equal in character that of Jamaica, it yet occupies a respectable place in the market. The quantity exported in 1851 was 15,848 puncheons. With respect to the cultivation of the sugar cane, by reason of the lowness of the land and the plan of drainage in use—namely, that known as the open-drain and round-bed method—the system of cultivation remains exactly as in the times of slavery, every part of the operations of culture being performed by manual labour. The plough and other implements have been tried, but cannot succeed in effecting a cheap and effective tillage till a system of covered drainage is resorted to. It is said that "were the system of drainage improved so as to admit of cattle and implemental labour, and were a mixed system in which the rearing and feeding of cattle formed a part, and a judicious system of manuring adopted, there is good reason to believe that three times our present return would be secured, and at little greater cost than the present." Among its other cultivated products are Indian corn, rice, tobacco, indigo, yams, sweet potatoes, and arrowroot. According to the governor's report for 1851, "the revenue has been flourishing, population augmenting, education spreading, crime diminishing, and trade increasing." The commercial state of the colony is still flourishing. In 1853 the value of imports from Great Britain was L.456,803; from British colonies, L.134,817; and from foreign countries, L.255,563—being in all L.847,183. Exports to Great Britain, L.958,616; to British colonies, L.26,856; to foreign countries, L.29,472—in all, L.1,014,944. Shipping, tonnage of, in 1853: inwards, from Great Britain, 42,815; from British colonies, 50,579; from United States, 17,822; and from foreign states, 13,772—in all, 124,988: outwards, to Great Britain, 49,339; to British colonies, 28,323; to United States, 5814; to foreign states, 25,630—in all, 109,106. In 1854 the computed real value of exports to Great Britain was L.1,636,267; of imports therefrom, L.492,646—of which L.460,867 was the computed real value of the manufactures and produce of the United Kingdom. The exports to Britain in 1854 included sugar, 898,240 cwt.; molasses, 39,035 cwt.; rum, 3,360,920 gallons; and coffee, 3664 lb. The revenue in 1853 was L.250,017, being L.32,002 above that of 1852; and the expenditure, L.236,557, or L.9487 above that of the previous year.

The constitution of Guiana still retains many traces of its Dutch origin. The government is vested in a governor and a court of policy; the latter composed of ten members, five being government officers (the governor, chief-justice, colonial secretary, attorney-general, and collector of customs), and five elected from the colonists by the College of Justice. This college is composed of seven members chosen for life by the inhabitants possessing the right of suffrage. The unofficial members of the court of policy serve for three years, and go out by rotation. The general legislative business is carried on by the court of policy, but it has no power of imposing taxes, that being reserved for the "combined court," composed of the court of policy and six representatives, termed "financial representatives," chosen by the people for two years, and who are annually summoned to "combine" with the court of policy for the purpose of transacting the financial business of the colony. In the combined court every member, whether a representative or a member of the court of policy, has an equal vote. The governor not only has a casting vote as president of the court of policy, but an absolute veto on all laws passed by a majority. The qualification for seats in the two legislative chambers are of four kinds; either, 1st, ownership of 80 acres of land, of which 40 must be in cultivation; or, 2dly, ownership of houses or land worth 1200 dollars per annum; or, 3dly, a leasehold interest in one or other of these, and to the same amount for a term of at least 21 years; or, 4thly, the possession of an income from any other source of 1440 dollars clear. Neither ministers of religion nor schoolmasters can, however, be chosen for either of the chambers. For electoral purposes the colony is divided into five districts. Electors must be in possession of an income of 600 dollars, or pay 20 dollars per annum of direct taxes, with some other minor qualifications.

The supreme civil court consists of a chief judge, two puisne judges, a secretary, registrar, and accountant. The supreme criminal court is composed of the three civil judges and three assessors chosen by ballot. The colony is also divided into nine judicial districts, each under the charge of a stipendiary magistrate appointed and removeable only by the secretary for the colonies, assisted by unpaid justices holding their commissions from the governor. Courts are held in each district two or three times a week.

The population of British Guiana is composed of aboriginal tribes and foreign settlers. The aborigines consist of six tribes of Indians, a copper-coloured, lank-haired race, and evidently members of the one great family which is spread over the entire continent of America. When slavery existed these were found useful allies and auxiliaries of the planters in capturing runaway negroes who had taken refuge in the "bush." They still enjoy British protection from the officers charged with the superintendence of rivers and creeks, who, while they look after the rights of the crown on ungranted lands, at the same time prevent acts of oppression or injustice on the part of the woodcutters and squatters towards the native Indians; and also, as far as possible, all quarrels among the different tribes and families. Nor is their spiritual welfare neglected. Numerous schools and missions have been established by the bishop for their instruction in the remotest parts of his diocese.

The census taken on 31st March 1851 gives the following results:—

	Demerara.	Essequibo.	Berbice.	Total.
Natives of British Guiana	51,044	15,776	19,631	86,451
Natives of Barbadoes............	3,644	794	487	4,925
Natives of other W. I. Islands...	2,756	1,077	520	4,353
African Immigrants	6,336	3,368	4,547	14,251
Madeirans	6,204	1,301	423	7,928
British, Dutch, & Americans...	1,486	269	320	2,088
Coolies from Hindostan	4,284	2,332	1,066	7,682
Unknown..........................	...	8	9	17
Total.........	75,767	24,925	27,003	127,695

The population of Georgetown, the capital (25,508), and of New Amsterdam (4633), are included in Demerara and Berbice respectively. Under the head Natives of British Guiana are comprised 2000 aborigines living near the cultivated parts of the territory; those beyond the settled districts are estimated at 7000.

Religion was here in a very neglected state till 1827, when British Guiana was included in the see of Bishop Coleridge; and shortly after this it was divided into parishes. In 1838 an archdeaconry was constituted, and there were then 13 clergymen of the Church of England in the colony. In 1842 the number had increased to 28, and the colony was erected into a bishopric, with a salary of L.2000 per annum attached. In 1851 there were 112 churches and chapels in British Guiana; of these 41 belonged to the Church of England, 15 to the Church of Scotland, 19 to the London Missionary Society, 15 to the Wesleyans, 6 to the Plymouth Brethren, 3 to the Roman Catholics, and 12 to other bodies. The numbers connected with each denomination were—Church of England, 39,787; Church of Scotland, 11,664; Wesleyans, 8438; London Missionary Society, 15,502; Roman Catholics, 9938; dissenters, whose denominations not ascertained, 13,639; Hindus and Mohammedans, 7037; not given, 21,710. The number attending public worship, by the religious census of 1851, was 33,034; of whom 10,210 were of the Church of England. The schools in the colony in 1852 connected with religious bodies, were 118; other schools, 32; the number of enrolled scholars, 10,877.

It is generally believed that this portion of South America was discovered by Vicente Yanez Pinzon, a Spanish navigator, in 1499. In 1580 the first settlement was formed by the Dutch on the rivers Pomeroon and Essequibo, and they afterwards established themselves in other places. The English began to form settlements about 1630 in the neighbourhood of the rivers Berbice and Surinam. Most of Guiana, however, remained in the hands of the Dutch till

1796, when it surrendered to the English. It was restored to the Dutch in 1802; but was again taken by the English on the breaking out of the war in 1803, and has since remained in their possession. In 1831 Demerara, Essequibo, and Berbice were formed into one colony, under the name of British Guiana. In 1834 slavery ceased in the colony, but parliament at the same time decreed that the negroes should undergo an apprenticeship—handicraftsmen and domestic servants for four years, and agricultural labourers for six. The inconvenience and trouble resulting from this system was so great that in 1838 an ordinance was passed by the local legislature discharging from their apprenticeships all those who by the imperial act were liable to serve for a further period of two years. The number of slaves for whom compensation was claimed was 82,824; and their value, according to an appraisement based on the average sales of the eight preceding years, was L.9,489,559. The amount of compensation actually paid was L.4,494,989. The imperial weights and measures were, by an ordinance passed in 1851, substituted for the Dutch weights and measures formerly in use.

(See R. H. Schomburgk's *Description of British Guiana*; Various articles in the *London Geographical Journal*; *Parliamentary Reports*; *Demerara after Fifteen Years of Freedom*, by a Landowner; Martin's *British Colonies*; *Reisen in Britisch Guiana*, von Richard Schomburgk; *The History of British Guiana, comprising a general description of the Colony, its climate, geology, staple products, and natural history*, by H. G. Dalton, M.D., 2 vols., London, 1855.)

GUIANA, *Dutch*, or *Surinam*, lies between British and French Guiana, being separated from the former on the W. by the River Corentyn, and from the latter on the E. by the Maroni; on the N. it has the Atlantic, and on the S. Brazil. It lies between N. Lat. 1. 30. and 6., and W. Long. 53. 30. and 57. 30., being about 300 miles in length from N. to S., and 260 in extreme breadth. Area, about 38,500 square miles. In physical geography, climate, productions, &c., it differs but little from British Guiana. The principal river is the Surinam, which flows northward through the centre of the territory, and falls into the Atlantic after a course of nearly 300 miles. It is navigable for large ships for about 4 leagues from its mouth. Along the coast and on the banks of the rivers are many settlements and plantations; and the higher parts of the country are occupied chiefly by the Maroons, the descendants of runaway negroes. In the last century they were very troublesome to the colonists, but they have now adopted more settled habits. Slavery has been recently abolished here by the Dutch government, but, in lieu of compensation, the slaves remain apprenticed and work without wages to their proprietors for twelve years. The colony is ruled by a governor appointed by the crown, and a council elected by the freeholders. Justice is administered by a supreme court, courts of minor jurisdiction, and a court of inheritance and orphans. The receipts in 1850 amounted to L.89,485; the expenditure to L.85,564. On 273 plantations, consisting of 366,548 acres, 48,815 acres were under cultivation. The chief productions are sugar, rum, molasses, coffee, cacao, and cotton. Its chief trade is with Holland. Imports in 1851, L.171,395; exports, L.236,162. At the close of 1850 the colony numbered 61,080 inhabitants—of whom 12,401 were Europeans and creoles, 8000 bush negroes, 1000 Indians, and 39,679 slaves. Of the religious sects, the Moravians amounted to 17,933, and the Jews to about 680. The live stock consisted of 168 horses, 59 mules, 5564 cattle, 3155 sheep, 454 goats, and 4664 hogs. The army consists of 610 men of all arms; and the navy of 11 vessels, chiefly small. Paramaribo, the capital, is situated on the right bank of the Surinam, about 10 miles from its mouth. It is built in the Dutch style, with wide and straight streets planted with orange trees; and the houses are generally two storeys in height, and built of wood. Pop. about 20,000. A little north of the town is the fort of Zeelandia, where the governor resides, and where are also most of the government establishments.

GUIANA, *French*, is the smallest and most eastern of the three colonies. It lies between N. Lat. 2. and 6., and W. Long. 51. 30., and 54. 30.; being bounded on the N. and N.E. by the Atlantic, E. and S. by Brazil, and W. by Dutch Guiana. It is about 250 miles in length from N. to S., and varies in breadth from 100 to 150 miles. Area, 27,560 square miles. It has a coast line of 200 miles, extending from the Maroni to the Oyapoc. The low alluvial tract along the coast is of great fertility. The mountain chains run E. and W., and are almost wholly of granite, but do not attain a great elevation. The country is abundantly watered; and the coast-lands appear to be less unhealthy than in British Guiana. The island of Cayenne, at the mouth of the Oyak, is about 30 miles in circumference, and is separated from the continent by a narrow channel. The roadstead at the mouth of the Oyak, though small, is the best on the coast, having everywhere from 12 to 13 feet of water. The capital, Cayenne, is situated on the northern side of this island, and contains 5220 inhabitants. The new town is well built, and has good streets; the government house is in the old town. The harbour is protected by a fort and several batteries. The colony is divided into two districts, Cayenne and Sinnamary, and fourteen communes. The government is vested in a governor, a privy council, and a colonial council composed of sixteen members elected by the colonists. The cultivated lands are estimated to be about $\frac{1}{80}$th of the whole territory. Besides the staples of British and Dutch Guiana, its productions comprise pepper (including Cayenne, which is so called from the island of that name), cloves, cinnamon, and nutmegs. Trade is chiefly with France and its colonies. In 1854 the official value of the imports into France from French Guiana was L.20,000; exports, L.192,000. The French first settled in Cayenne in 1604; the British and Portuguese captured the colony in 1809, but restored it to the French in 1814, in whose possession it still remains. It has recently been made a place of banishment for French political offenders, and in 1852, 2500 of these were sent out. Pop. about 22,000, of whom about 15,000 are emancipated slaves.

GUIBERT, JACQUES-ANTOINE-HIPPOLITE, Count de, a well-known writer on tactics, was born at Montauban, on the 12th of November 1743. Before he had completed his fourteenth year, he accompanied to Germany his father, who acted as major-general to the army commanded by Marshal de Broglie; and he served, either as captain in the regiment of Auvergne, or as an employé in the staff, during the six campaigns of the war of 1756. He also displayed great zeal in raising and training the Corsican legion, of which he was appointed colonel-commandant in 1772. The year following he published his *Essai Général de Tactique*. But not wishing to abide, in his own country, the explosion which such a work was calculated to produce, he set out for Germany, which opened to him a vast field of instruction. He repaired to Prussia, and although a species of celebrity had preceded him, he had still considerable difficulties to encounter. Among these were certain prepossessions of Frederick, who judged severely the theoretical attainments and views of the young tactitian, and who besides was not by any means satisfied with Guibert's views of the Prussian system. With this view he addressed a letter, in explanation and in defence, to the Prussian monarch, who was so well pleased with the composition that he received the writer with particular distinction. Ever since the year 1772 Guibert had conceived the design of also entering on the career of literature; and, from year to year, after his return from Prussia, compositions of his, either in the shape of tragedies, or of panegyrics on the great men of France, procured him much reputation in the *salons*, where they were generally read by the author. He was, however, recalled to his original occupation, by the appointment of the Count de Saint-Germain to the department of war; and having been honoured with the confidence of that minister, he had the rare merit of not abandoning him in his disgrace. In 1776 he was made colonel-commandant of the regiment of Neustrie; in 1782, brigadier-general; in 1788, *maréchal-de-camp*, or major-general; and next inspector of infantry in the province of Artois. In 1787 he was appointed member and reporter of the council of administration in the department of war. But as Guibert, in the discharge of his functions, combined his own peculiar ideas with those which the deliberations of the council rendered common, the whole appeared to emanate from the reporter, whose proper duty it was merely to give expression to the views of the council; and it was consequently against him that all the complaints and accusations of the discontented were directed. We have already seen that no species of ambition was foreign to Guibert. Accordingly, in 1789, he aspired to become a member of the states-general of the kingdom, and thereby prepared for himself the bitterest mortification which he had ever yet experienced. His pretensions, both as a military man and a writer, had provoked censure, and even excited hostility. He was accused of having attempted to subject officers to imprisonment in irons; proposed to introduce the cane as an instrument for chastising the common soldiers; and recommended the detestable barbarity of hamstringing deserters. Guibert replied by a most formal denial of these imputations, but met with no credit; and in the assemblage of the bailliage of Bourges, the people went so far as to refuse him a hearing. Inconsolable at this injustice, Guibert retired from public life; and, after a short illness, died on the 6th of May 1790, in the forty-seventh year of his age.

His works are,—*Essai Général de Tactique*, already mentioned, Liège, 1773, in one vol. 4to, and two vols. 8vo; *Eloge de Catinat*, Edinburgh (Paris), 1775, in 8vo; *Connétable de Bourbon*, a tragedy; *La Mort des Gracques*, a piece in three acts; *Anne de Boulen*, the best of his dramas; *Eloge Historique de Michel de l'Hôpital, Chancelier de France*, 1777; *Défense du Système de Guerre Moderne, ou Réfutation complète du Système de M. de Mesnil-Durand, par l'auteur de l'Essai Général de Tactique*, Neufchâtel, 1779, in two vols. 8vo; *Discours de reception à l'Académie*, 1786; *Eloge du Roi de Prusse*, London (Paris), 1787, in 8vo; *Letter addressed to the National Assembly, in the name of the Abbé Raynal*, Marseilles, 1789, in 4to; *Traité de la Force Publique*, Paris, 1790, in 8vo, the last production which he acknowledged; *Journal d'un Voyage en Allemagne fait en 1773 par Guibert*, Paris, 1803, in two vols. 8vo; *Œuvres Militaires de Guibert*, published by his widow, Paris, 1803, in five volumes 8vo; *Voyages de Guibert dans diverses parties de la France et en Suisse, faits en 1775, 1778, 1784, et 1785, ouvrage posthume*, Paris, 1806, in 8vo; A volume of *Eloges*, including that of *Claire-Françoise de l'Espinasse*, Paris, 1806, in 8vo.

But of all the works of Guibert, that by which he is best known is his Essay on Tactics, so often quoted and referred to under the head ARMY. (J. B—E.)

GUICCIARDINI, FRANCISCO, a celebrated Italian historian, was born at Florence in 1482. His ancestors had held the most distinguished offices in the Florentine republic. Simon Zanuccio Guicciardini was gonfalonier of justice in 1302; his grandfather, an able politician and a great warrior, beat the Genoese near Sarzano in 1412, and defeated the troops of Sixtus IV. in 1478; and Pietro, the father of the historian, acquired a great reputation by his talents for the conduct of public affairs. Francisco Guicciardini was originally intended for the bar, to which he was at length called; and so great was his success that, at the age of twenty-three, he became professor of jurisprudence at a time when all the chairs in Italy were occupied by the ablest jurisconsults. His inclination, however, leading him to public affairs, he quitted his chair, and in 1512 was appointed ambassador to Ferdinand king of Aragon. Having succeeded in gaining the favour of that prince, he thus secured a powerful protector to the Florentine republic. Pope Leo X., a discriminating judge of real merit, called Guicciardini to his court, loaded him with honours, and named him governor of Modena and Reggio, at the same time conferring on him unlimited powers. In this capacity he also served under the pontificate of Adrian VI.; nor did his firmness, his beneficence, and his equity, fail to secure him the attachment of the people over whom he had been placed. But as Romagna was dreadfully distracted by the irreconcilable factions of the Guelphs and Ghibelins, Clement VII., on succeeding to Adrian VI., sent thither Guicciardini, who in a little time re-established tranquillity in that unhappy country, caused the most rigid justice to be enforced, founded useful establishments, opened new roads, and ultimately rendered himself the idol of all parties. Being afterwards appointed lieutenant-general to the Holy See, he acquired much glory by his defence of Parma, when besieged by the French; and after the death of Giovanni de' Medici, the Florentine republic chose him to succeed that famous captain in the command of the black bands, the *élite* of the Italian troops. But as Clement VII. required a man of tried ability and courage, he obtained the consent of the Florentines to retain Guicciardini some time longer in his service. The city of Bologna was about to escape from the domination of Rome; the senate had raised the standard of revolt; the great family of the Pepoli openly aspired to the supreme power; the vindictive passions were indulged without restraint, and assassinations multiplied. Guicciardini, in the capacity of governor, presented himself in this city, whither his renown had preceded him. His severe deportment, his activity, his eloquence, tranquillized the people, disarmed the senate, and deprived the Pepoli of all hope of obtaining the object they had in view. By his talents, prudence, firmness, and justice, Bologna, which would otherwise have been lost for ever, was saved to the patrimony of St Peter. After this expedition, Guicciardini, notwithstanding the entreaties of Clement, returned to his own country, where he lived in retirement, being wholly occupied with the composition of his history, which he commenced about the end of 1534. But this did not prevent him from rendering the most important services to Florence. His counsels moderated the prodigality and ambition of Alessandro de' Medici; and, at the suggestion of Naples, he effected an advantageous arrangement between this prince and Charles V. Alessandro having been assassinated in 1536 by one of his near relatives Lorenzino de' Medici, Cardinal Cibo immediately assembled the council, when it appeared that all the other members were inclined for a republican government. But Guicciardini perceiving that by this means the country would become a prey to civil war, declared in favour of a monarchical government; and as his persuasive eloquence at length overcame the predilections of the council, Cosmo de' Medici was proclaimed sovereign of Florence. From this moment, Guicciardini took no further concern in public affairs; and after having passed four years in study and retirement, he died in May 1540.

The memory of this able and excellent person is endeared to men of letters by his *History of Italy*, Florence, 1561, in folio, or two vols. in 8vo. The original edition, though much sought after, is incomplete; that of Venice, 1567, in 4to, is augmented by four books, viz., from seventeen to twenty inclusive; and that of Venice, 1738, in two vols. folio, has, besides, a life of the author by Manni, with a fragment containing some passages previously inedited. But the first complete edition is that of Friburg in Brisgau (Florence), 1775, 1776, in four vols. 4to, printed from an autograph manuscript in the Magliabecchi library, under the auspices and care of the canon Bonso Pio Bonsi, who has supplied the defects of former editions, and otherwise discharged his editorial duties with fidelity and talent. The most correct and complete edition is that by Professor

Rosini of Pisa, 10 vols. 8vo, 1819–20, prefaced by an essay on Guicciardini's life and writings. The history has been translated into English by Chevalier Austin Parke Goddard, 10 vols. 8vo, Lond., 1753–61. The *History of Italy* commences in 1490, and terminates in the month of October 1534. It consists of twenty books, sixteen of which are, in the opinion of the best critics, of superior merit; but the last four are little more than draughts of memoirs, death having prevented the author from bestowing on them all the care and attention which the subject required. The historian commences by giving an exposition of the tranquil condition of Italy before the breaking out of the troubles which desolated its finest provinces. He then proceeds to describe the bloody wars which the French carried on in that country, under three successive kings. By these the face of Italy was almost entirely changed; the popes aggrandized themselves by the ruin of several petty states; Naples and Milan, torn from their respective princes, recognised the domination of Charles V.; and Genoa, which had thrown itself into the arms of France, recovered its liberty under the protection of the same monarch, who, on the other hand, gave a sovereign to the republic of Florence. If, in this revolution, the greater part of the princes of Italy maintained themselves, they owed their preservation to their own weakness, and a timely submission to a conqueror whom fortune seemed to lead on, by rapid strides, towards universal monarchy. Such, in a few words, is the grand spectacle presented by the *History of the Wars in Italy*, a production which has immortalized the name of Guicciardini. The hatred of vice, which breaks out in every page of his work, satisfies the reader as to the probity of the historian, who was, moreover, concerned in most of the events which he relates, and performed a brilliant part both in the cabinet and in the field. His style, sometimes nervous and sublime, sometimes lively and rapid, always noble, perspicuous, and appropriate to the subject, fixes the attention and hurries along the mind of the reader. His reflections, equally judicious and profound, show the wise republican, the able politician, the enlightened philosopher; as the friend of humanity and justice, he unsparingly attacks the abuses of the sovereign power, and vindicates that virtue which the great so often profane for the gratification of their interests and passions. He has left us faithful portraits of the celebrated men of his time; he has represented with equal genius and accuracy the force and manners of the nations which figure in his history; and he has made us acquainted with the real interests of the princes of his time, as well as with the origin of those jealousies which then divided the powers of Europe. Guicciardini has been reproached with the length of the harangues which he puts into the mouths of his characters; but these he has enriched with so much eloquence, with thoughts so new and profound, with images so just and striking, that they are always interesting, and never felt as impeding the progress of his narrative. He has also been accused of prejudice against the French; yet he never exaggerates their losses in battle; and Father Daniel, in his history, has merely copied the narrative of Guicciardini. If the latter, like several French authors, has traced an unfavourable portrait of Charles VIII., he has, on the other hand, done ample justice to the equity and the virtues of Louis XII., the valour and prudence of La Tremouille, and the brilliant qualities of Gaston de Foix and Francis I.; whilst, in speaking of the Italian and French militia, he always declares in favour of the latter. These, and other facts of a similar description, which might easily be produced or referred to, are sufficient to show that the charge of partiality is groundless, and that what has been mistaken for prejudice is nothing but the severity of truth. Guicciardini is also the author of *Advice and Counsel in matters of State*, Antwerp, 1527, in 8vo.

GUICCIARDINI, *Luigi*, nephew of the preceding, was born at Florence, in the year 1523. He held different employments under Alessandro de' Medici and his successor Cosmo II.; then he travelled, and remained a long time at Antwerp, where he obtained the favour of the Duke of Alva; but having reflected on this general's system of government, in a work which he published (*Memoirs*), he was thrown into prison, whence he was liberated only through the intercession of the Grand Duke of Tuscany. The remainder of his life presents no event worthy of notice, and seems to have been chiefly passed in the composition of his works. These are *Memorie*, &c., or Memoirs of what passed in Savoy from 1530 to 1565, Antwerp, 1565, in 4to. *Raccolta dei Detti e Fatti notabili*, 1581, in 8vo; *Descrizione*, &c., or Description of the Low Countries, Antwerp, 1567, in fol.; *Ore di Recreazione*, Florence, 1600, in 12mo. Luigi Guicciardini died in 1589.

GUIDO ARETIN. See ARETINO.

GUIDO RENI, one of the most famous and distinguished painters of the Italian school, was born at Bologna in 1575. He was trained first by Denis Calvart (see CALVART), and finally by the Caracci; but having had the misfortune to excite the jealousy and suspicion of the latter, he deemed it expedient to remove to Rome, where he studied specially Raffaelle and Caravaggio, whose works had the strongest influence in moulding his yet unformed style. A commission from the Pope Paul V., was among the first earnests of his future distinction; but as he had great difficulty in getting payment for his work, he quitted Rome in disgust, and retired to his native town, where he extended his already wide reputation. He afterwards returned to Rome, where he seems to have contracted habits of gambling and dissipation. To repair his losses, he seems to have begun the practice of painting swiftly and carelessly; but his spirits gave way, and he sank into a sort of lethargy, from which nothing could rouse him. He died in great poverty in 1642. Guido's personal beauty was so striking, that when in the *atélier* of the Caracci, he often sat to Ludovico, whose favourite pupil he was, as a model for an angel. His own pieces are distinguished by a grace, lightness, elegance, and delicacy, that will secure for him a lofty niche in the artistic temple of fame. For a detailed criticism of his works, see PAINTING; and Lanzi's *Storia Pittorica della Italia*.

GUIDONES, a company of priests established by Charlemagne at Rome, to conduct and guide pilgrims to Jerusalem, to assist them if they felt sick, and to perform the last offices to them if they died.

GUIENNE, or GUYENNE, an old province in the S.W. of France, the capital of which was Bordeaux. In 1790 it was divided into the departments of Gironde, Landes, Dordogne, Lot, Aveyron, and Lot-et-Garonne.

GUIGNES, JOSEPH DE, a learned orientalist, born at Pontoise on the 19th of October 1721, was, in 1736, placed under the celebrated Fourmont by his cousin M. le Vaillant, professor in the university. Being endowed with the happiest dispositions, and directed by an able master, he, in a short time, acquired a knowledge of Chinese, and of the different idioms of the East. When Fourmont presented to the king his Chinese Grammar, in the year 1742, the young De Guignes accompanied him, and was received in the most flattering manner by the monarch, who immediately conferred on him a pension. On the death of his master, which took place in December 1745, De Guignes succeeded him at the Royal Library in the office of secretary-interpreter of the eastern languages. The Memoir on the Origin of the Huns having given the learned world a foretaste of the talents and erudition of De Guignes, he was admitted a member of the Royal Society of London in 1752, and an associate of the Academy of Belles-Lettres the following year. About the same time he was also appointed royal censor, and attached to the *Journal des Savans*. These different favours were the just recompense of the important labours in which M. de Guignes was engaged. The first two volumes of his History of the Huns appeared in 1756; and in 1757 the chair of Syriac in the Royal College having become vacant by the death of Jault, De Guignes was appointed to succeed him. Upon this occasion he pronounced a Latin discourse, the principal object of which was to prove, what certainly needed little demonstration, that the kings of France were much more friendly to letters than the princes of Asia. In 1769 he became keeper of the antiquities in the Louvre, and, in 1773, pensionary of the Academy of Belles-Lettres; in 1774 he resigned the chair of Syriac, not choosing to consent to the re-union of the Royal College with the university; and, lastly, in 1785, he was named one of the committee appointed by the academy for the publication of Notices of Manuscripts. The Revolution did not deprive De Guignes of his pensions, which, notwithstanding his great labours, had never been demanded by him; but it deprived him of his moderate allowance as pensionary of the academy, keeper of antiquities in the Louvre, and redacteur of the *Journal des Savans.* Faithful to his principles, and to the cultivation of letters, however, he made no remonstrance, declined accepting any favour, and consoled himself for the sufferings of his country, and the personal privations he experienced, by applying with greater assiduity to his favourite pursuits. These he continued, without intermission, until his death, which took place at Paris on the 19th of March 1800. De Guignes left a son, who had been consul at Canton, and who, on his return to France, published an account of his voyage in three volumes 8vo, and a Chinese Dictionary. The following is a list of the printed works of the father :—

Abrégé de la Vie d'Etienne Fourmont, with a notice of his works, Paris, 1747, in 4to; *Mémoire Historique sur l'Origine des Huns et des Turcs,* Paris, 1748, in 12mo; *Histoire Générale des Huns, des Turcs, des Mogols, et des autres Tartares occidentaux, avant et depuis J. C. jusqu' à present,* preceded by an introduction containing historical and chronological tables of the princes who have reigned in Asia, Paris, 1756, 1758, in five vols. 4to; *Mémoire dans lequel on prouve que les Chinois sont une colonie Egyptienne,* Paris, 1759, 1760, in 12mo; The *Chou-king,* or sacred book of the Chinese, with a translation corrected from that of Father Gaubil, and most useful notes, Paris, 1770, in 4to; An edition of the *Eloge de Monkden* and of the *Art Militaire des Chinois,* 1770, 1771; Twenty-eight papers in the *Mémoires of the Academy of Inscriptions.* These papers or memoirs may be divided into three classes; the first of which has for its object to develope more fully various points which are only treated cursorily in the History of the Huns; the second includes the papers intended to establish his system of the Egyptian origin of the Chinese; and the third comprehends those of a miscellaneous character, such as the memoir on the commerce of the French in the Levant before the Crusades, that on the Oriental Zodiac, and observations on the origin and antiquity of the Indians, as well as on the geography of their country. Besides the works mentioned above, De Guignes left several manuscripts, particularly, *Notices d'Ecrivains Arabes; Mémoire sur le Commerce des Chinois avec les Russes; Histoire de la Chine,* translated from the Chinese Annals, and divided into three parts; *Mémoires Historiques et Géographiques sur l'Afrique, d'après les auteurs Arabes.* Such were the works which occupied the life of this scholar. Considered as a learned man, he may be said to have possessed vast knowledge, and to have employed it in the most useful manner. Although he cannot be called an elegant writer, his style is easy and clear; and even the paradoxes which he defended prove, by his ingenious approximations and original views, that he was endowed with a lively imagination and extraordinary sagacity.

In his history, the object of De Guignes was to collect facts rather than to digest them according to a rigorous chronology; and the disorder which, in this respect, reigns in his work, proceeds partly from the multitude of sources whence he derived his information, and partly from the vice of the oriental writers amongst whom the irregular method of computing dates renders it impossible to restore the precise chronology of events. On this ground the writers in the *Journal de Trevoux* attacked the History of the Huns. De Guignes replied to this criticism, in a letter inserted in the *Journal des Savans* for 1757, and also at the end of the fifth volume of his History. The journalists rejoined; and the dispute terminated by a note appended to the same volume, in which the author refers to the *Annales Chinoises.* The History of the Huns has been translated into German by Daenhert, who appears to have done ample justice to the original. (J. B—E.)

GUILD (from the Saxon *guildan,* to pay), signifies a fraternity or company, because every one was *gildare,* that is, had to pay something towards the charge and support of the company. As to the origin of guilds or companies in Britain, it was a law among the Saxons that every freeman of fourteen years of age should find sureties to keep the peace, or be committed. This led to the formation among neighbours of associations, each consisting of ten families, which became bound for one another, either to produce him who committed an offence, or to make satisfaction to the injured party; and that they might the better do this, they raised a sum of money amongst themselves, which they put into a common stock, and when one of their pledges had committed an offence, and fled, then the other nine made satisfaction out of this stock, by payment of money, according to the offence. Because this association consisted of ten families, it was called a *decenary*; and hence arose other kinds of fraternities. But as to the precise time when these guilds had their origin in England there is nothing certain to be found; since they were in use long before any formal license was granted to them for such meetings. It seems to have been about the close of the eleventh century, according to Anderson (*History of Commerce,* vol. i., p. 70), that merchant-guilds, or fraternities, which were afterwards styled corporations, came first into general use in many parts of Europe. Madox (*Firma Burgi,* chap. i., sect. 9) thinks they were hardly known to our Saxon progenitors, and that they might probably have been brought into England by the Normans, although they do not seem to have been very numerous in those days. The French and Normans might perhaps have borrowed them from the free cities of Italy, where trade and manufactures flourished at a much earlier period, and where such communities appear to have been first in use. These guilds are now companies or associations having laws and orders made by themselves, in virtue of authority from the prince to that effect.

GUILD, in the royal burghs of Scotland, is still used for a company of merchants, who are freemen of the burgh. Every royal burgh has a dean of guild, who is the next magistrate below the provost.

GUILD, *Gild,* or *Geld,* is also used by ancient writers to signify a compensation or mulct for an offence.

GUILD-HALL. See LONDON.

GUILDFORD, a municipal and parliamentary borough, and market-town of England, county of Surrey, on the right bank of the Wey, 29 miles S.W. of London. It is the chief town of the county, is governed by a mayor, four aldermen, and twelve councillors, and returns two members to parliament. It stands on the declivity of a chalk down, at the foot of which flows the Wey, here crossed by a bridge of five arches. The town consists chiefly of one long, wide, and well-built street, and is divided into three parishes, each of which has a parish church. It has a fine old town-hall, a county-hall, theatre, market-house, county gaol, house of correction, union workhouse, hospital, grammar-school, blue-coat and other schools, &c. The Guildford Institute, formed in 1844, has a museum, library, and reading and lecture rooms. It has an iron-foundry, and paper, powder, and corn mills on the Wey. Guildford was a residence of the Anglo-Saxon kings; and traces of an ancient palace are still to be found. On an eminence on the south side of the town stands the ruined keep of a castle of Norman date. A considerable trade is carried on by means of the Wey, in corn, malt, timber, &c. Market-days Wednesday and Saturday. Pop. (1851) 6740. Electors, 648.

GUILLIM, JOHN, a celebrated heraldric writer, was born in Herefordshire about the year 1565. Having completed his education at Brazen-nose College, Oxford, he became a member of the College of Arms in London; and he was made rouge-croix pursuivant, in which post he died in 1621. He published, in 1610, a work entitled the *Display of Heraldry*, folio, which has gone through many editions. To the fifth, which appeared in 1679, was added a *Treatise of Honour Civil and Military*, by Captain John Logan, which is generally considered the standard work on the subject it discusses.

GUILLOTINE, an instrument for inflicting capital punishment by decapitation. It consists simply of two upright posts, surmounted by a cross-beam, and grooved for the purpose of guiding an oblique-edged knife, the back of which is heavily weighted to make it fall swiftly and with force, when the cord by which it is held aloft is let go. It takes its name from Joseph Ignace Guillotin, a physician in Paris, who was a member of the French National Assembly at the time of the Revolution, and proposed its adoption by the Assembly. In a decree of March 20, 1792, its adoption was proclaimed. It is a mistake to suppose that Guillotin was the inventor of this instrument, as is often alleged. Centuries before his day it had been in use in many parts of Germany, in England, Scotland, and Italy. By the Italians it was called Mannaia; and an engraving of it, as used in Italy, may be seen in the *Questiones Symbolicæ* of Achilles Bocchius, printed at Bologna in 1555. It is also minutely described by Father Labat in his *Voyage en Italie*. In the *Chronique de Jean d'Auton*, first published in 1835, there are some curious details of an execution that took place at Genoa in 1507, with a machine, of which the guillotine is only an ingenious adaptation. In the museum of the Antiquarian Society of Edinburgh is preserved to this day the rude guillotine, or *Maiden*, by which the famous Regent Morton was decapitated. In the *Description of Tweeddale*, Pennicuik alludes to this event in the following terms:—"This mighty earl, for the pleasure of the place and the salubrity of the air, designed here a noble recess and retirement from worldly business, but was prevented by his unfortunate and inexorable death, three years after, anno 1581, being accused, condemned, and executed by the *Maiden* at the cross of Edinburgh, as art and part of the murder of King Henry, Earl of Darnley, father to King James VI., which fatal instrument, at least the pattern thereof, the cruel regent had brought from abroad to behead the Laird of Pennicuik, who, notwithstanding, died in his bed, and the unfortunate earl was himself that handselled that merciless *maiden* who proved so soon after his own executioner."

Though Dr Guillotin gave his name to this engine of death, he had in reality nothing to do with it beyond bringing it under the notice of the National Assembly. The real mover in the affair was the famous surgeon Antoine Louis, but his designs would never have been carried out but for the mechanical ingenuity of a young German by name Schmitt, then residing in Paris, who, after a great many trials and experiments, succeeded in making the guillotine, as it now works. The first execution with the new machine took place at Paris, April 25, 1792. A curious question has been started in connection with the use of the guillotine. The celebrated anatomist Sömmering, denounces it as too rapid in its operation, and maintains that sensation does not cease immediately after the head of the sufferer has been severed from the body. Among other instances he adduces that of Charlotte Corday, whose face seemed to blush with indignation, when the executioner, holding up the head to the public gaze, struck it with his fist. This subject is fully discussed in the *Moniteur* for November 1795, and in Sédillot's *Reflexions historiques et Physiologiques sur le supplice de la Guillotine*, and in the *Anecdotes sur les Décapités*.

It is sometimes, though erroneously, stated that Dr Guillotin, like Phalaris, was the first to hansel the work of his own hands. He survived the Revolution, and died in 1814.

GUIMARAENS, a fortified city of Portugal, province of Entre-Douro-e-Minho, 28 miles N.E. of Oporto, between the rivers Sollio and Visela, in N. Lat. 41. 25., and W. Long. 8. 15. It is well built on the acclivity of a hill. The chief manufactures are leather, paper, hardware, cutlery, cottons, linens, &c. Hot sulphurous springs, with a temperature of 164° Fahr., have retained their celebrity, and have been much frequented here since the foundation of this city in 500 B.C. It was made the capital of Portugal by Henry of Burgundy, in 1107 A.D.; and Alfonso I., as well as Pope San Domaso, were born here. The population is now nearly 10,000.

GUINEA, the name assigned to a large tract of country on the W. coast of Africa, commencing at Cape Verga, in about 10° N. Lat., and terminating with the Cameroon Mountains in the Gulf of Biafra. These are the limits more commonly given to what is called Guinea; by some they are greatly extended, so as to comprise the whole of the Portuguese settlements south of the equator, under the name of Southern Guinea, while the coast north of the equator is called Northern Guinea.

The term Guinea is not of African origin, or at least not among those to whom it is applied. There is, according to Barbot, a district of country north of the Senegal known by the name of *Genahoa*, the inhabitants of which were the first blacks that the Portuguese encountered in their explorations along the coast in the fifteenth century; and they applied this name indiscriminately afterwards to all the black nations which they found farther south. In the two succeeding centuries it was applied in a more restricted sense to that portion of the coast which is now better known as the Gold and Slave Coasts; owing to the fact, perhaps, that this region for a time offered a larger number of slaves for the foreign market than any other part of the country. The natives here acknowledge this term as applied to themselves, but it was undoubtedly borrowed in the first instance from the Portuguese.

The physical aspect of the country, as might be inferred from the large extent we have under consideration, is very variable, but is characterized everywhere by excessive richness of natural scenery. In the region of Sierra Leone, Cape Mount, and Cape Mesurado, the eye rests on bold headlands and high promontories covered with the richest tropical verdure. In the vicinity of Cape Palmas there are extended plains, slightly undulating, and covered with almost every variety of the palm and palmetto. On the coast of Drewiss the country rises into table-lands of vast extent, and apparently of great fertility. The Gold Coast presents every variety of hill and dale; and as we approach the equatorial region we are saluted by mountain scenery of unrivalled beauty and surpassing magnificence.

The inhabitants consist chiefly of the following tribes:—The Vais, the Manou or Kru, the Kovakeras or Avekroom, the Inta, the Dahomey, Ashanti, and the Benin. There are no large or extended political organizations, with the exception, perhaps, of the kingdoms of Ashanti and Dahomey, and neither of these has a larger population or greater extent of territory than the smaller kingdoms of Europe. For the most part, the people live together in independent communities, of not more than eight or ten villages, and with an aggregate population of from 2000 to 25,000 or 30,000. In these different communities they have no written forms of law, but are governed for the most part by certain traditional usages that have been handed down from generation to generation. Nominally, monarchy is the only form of government acknowledged among them; but, when closely scrutinized, their systems show much more of the popular and patriarchal than of the monarchical element. They are essentially a pagan people; but in their religious notions and idolatrous worship they differ very much from each other. There are many decided traces of the Jewish origin. Among these may be specified the rite of circumcision, which, with the exception of the Kru or Manon family, is, we believe, universal; the division of the tribes into families, and in some cases into the number of twelve; bloody sacrifices, with the sprinkling of blood upon their altars and door-posts; the observance of new moons; a formal and specified time for mourning for the dead, during which period they shave their head and wear tattered clothes; demoniacal possessions, purifications, and various other usages of probable Jewish origin.

Respecting the natural products and trading capabilities of the country, the articles exported consist chiefly of ginger, gum, mendobi (Guinea grains, a species of seed), palm-oil, some ivory, a wood used for dyeing called camwood, and which is worth in England about L.15 sterling a ton. Vessels visiting that coast take on board—at Sierra Leone, or on the coast of Malagueta, between Cape Mesurado and Cape Palmas—some black sailors, called krumen, who are of great use in doing the heavy work on board, and for boat service; thus saving the European seamen from exposing themselves too much to the sun's rays, &c. The services of these krumen are recompensed with two or three pieces of cotton cloth per month each. Their chief food is rice, which may be purchased at a very cheap rate on the coast of Malagueta; the price of a "kru" (a measure of capacity weighing about 30 lbs.) being a fathom and a half of cotton cloth, or any other article of proportionate value.

On the coast of Malagueta (Grain Coast), the articles received principally in barter are rice and millet; also ivory, palm-oil, and camwood, especially at Monrovia, the capital of Liberia. At Sierra Leone, the pepper-tree (called malagueta) is cultivated on an extensive scale, and its fruit—Guinea pepper—after being dried, is purchased in large quantities by the Americans, and imported into the United States.

English muskets, gunpowder, rum, and tobacco, are the principal articles of traffic on the whole of the coast as far as Onim at the bottom of the Bight of Benin.

At Jaque Lahoo and Jaque Jaque, two considerable towns, situated at the extremity of the bight formed by Cape Palmas and Cape Three Points, commences the trade in gold-dust; here also a considerable quantity of palm-oil and some ivory are found. After passing these towns, the European settlements commence. The first are Great Bassam and Assine, belonging to France, and situated at the mouths of the rivers of the same names. Five leagues to the west of Cape Three Points, is the small Dutch fort of Axem; and on the other side of the same cape is the English port of Dick's Cove.

From Cape Lahoo to Acora, and to all the European settlements on the coast, the monetary standard is the "ake" (ackie) of gold-dust, which weighs half a dram English, and is worth nearly 5s. The kru on this part of the coast is almost double that assigned to it on the coast of Malagueta—averaging L.50, more or less.

Between Dick's Cove and the castle of St George of the Mine (S. Jorge da Mina) are situated the small forts of Serunde, Sanca, and Commendo; after which we come to the first large European settlement, viz., the castle of St George of the Mine, belonging to Holland. The castle is a Portuguese structure, and was formerly the most important of the Portuguese colonies on this coast. Next to it is Cape Coast Castle, belonging to England, and situated in sight of the former. The next place is Annamaboo, a small English fort, formerly abandoned, but where for some years past trade has been again in some degree developed. To this fort succeed others in ruins, as Winebah and Assam. Millet is found in abundance at these places, as well as palm-oil and gold-dust.

Proceeding along the coast, we come to the great English settlement of Acora, where there are at present two fortresses. The first, that of St James, was built by them many years since; the second, that of Christianburg, was purchased from Denmark, together with all its possessions on that coast, in the year 1850. Then follow the small settlements of Ningo; after passing which, Cape St Paul, a little to the east of Rio da Volta ("Return River"), is doubled.

From Cape St Paul to Onim or Lagos, many negro towns or villages are met with stationed along the coast. These communicate with each other by means of the lake situated at no great distance inland from the beach; and then the ford converges to the principal points, which are Quita, Popo-pequeño, Ajuda, Porto Novo, and Onim.

The trade which formerly flourished at all these places was that in slaves; but for some years past that in palm-oil, or *den-den*, has greatly developed itself, the quantity produced amounting annually to more than 7000 tons, which are shipped to England, America, and France.

On this section of the coast there are no European establishments, properly so called; but at Ajuda, Porto Novo, and Onim, there are factories; and Europeans are also resident in the country, and traffic with vessels, as they do at those establishments.

The trade of the Benin, Brass, Bonny, Calabar, and Cameroon Rivers, is all in palm-oil, and carried on exclusively by the English.

The whole coast has been arbitrarily divided into five parts:—

1. The Sierra Leone district, from Cape Verga to Cape Mesurado.
2. Malagueta, Pepper or Grain Coast, from Cape Mesurado to Cape Palmas.
3. The Ivory Coast, from Cape Palmas to Cape Three Points.
4. The Gold Coast, from Cape Three Points to the River Volta.
5. The Slave Coast, or Benin district, from the River Volta to the Cameroons. (A. P.)

GUINEA, *New*. See AUSTRALASIA.

GUINEA, a gold coin formerly struck and current in Britain, and so denominated because the gold of which the first specimens were struck (*temp*. Car. II.) was brought from the coast of Guinea; and for a like reason it originally bore the impression of an elephant. The value of the guinea varied greatly at different periods, but latterly it was worth 21 shillings. Its weight was 5 dwts. 9·4125 grs. On the introduction of the *sovereign*—first coined in 1817—the old guinea coinage was gradually superseded. See COINAGE, and MONEY.

GUINEA-Fowl. See index to ORNITHOLOGY.

GUINEA-Pig. See index to MAMMALIA.

GUINGAMP, a town of France, capital of a cognominal arrondissement in the department of Côtes-du-Nord, on the right bank of the Trieux, 17 miles W.N.W. of St Brieuc. It was formerly surrounded by walls, part of which still exists. It has an old parish church with a tower and spire, and several other good buildings; also manufactures of *ginghams*, to which it gives name; of linen fabrics, thread, leather, hats, &c.; and some trade in wine, brandy, cattle, and agricultural produce. Pop. (1851) 6718.

GUIPUZCOA, the most easterly of the four Basque provinces of Spain, bounded on the W. by Biscay, S. by Alava, E. and N.E. by Navarre, N.E. by the Bidasoa, the mutual boundary between it and France. Its form is nearly that of a right-angled triangle, having the hypothenuse towards the S.E., and its area is nearly 600 square miles. Its coast is so much indented, that it contains no fewer than nine harbours—none of which, however, are very important. From the immense variety of surface in mountain, hill, and valley, the scenery of this small province is highly picturesque and romantic. Lofty mountains—partly clothed with evergreen forests, and partly barren—shoot out from the Pyrenees, and spread over the whole surface. In this province commences the Cantabrian ridge, to which belongs the Alzanja, over which the great road of the Romans was conducted. To the coast belong the Cabo San Antonio, and the Cabo de Higuera; and numerous small bays, forming good harbours—Orio, Zarauz, Guetaria, Zumaya, Deva, Motrico, Fontarabia, Le Passage, and San Sebastian. The streams are all short, rapid, unnavigable, and fall into the Bay of Biscay; the principal of these are the Deva, Urola, Oria, Urumea, Lezo, and Bidassoa. The soil—especially in the lower valleys—is very fertile, and is cultivated very carefully; but, from the nature of the surface, agricultural labours are prosecuted with considerable difficulty. The climate, though moist, is mild, pleasant, and healthful; and the inhabitants often attain to a great age. The frequency of rain preserves the freshness of the verdure throughout most of the year; but thunder-storms often occur during December and January. The chief wealth of the province arises from its mineral stores and excellent fisheries, which supply the neighbouring provinces of Alava, Navarre, part of Castile, and Aragon, with excellent sea-fish. The grain raised falls considerably short of what is necessary for home consumption. The minerals chiefly wrought are iron, of excellent quality, being smelted with wood; argentiferous lead, copper, marble, and gypsum. The people are remarkable for their fine physical form, and bold, manly spirit; and, notwithstanding the simplicity of their manners, the prominent features of their character are industry, honesty, benevolence, gallantry. They are fond of games requiring bodily strength and exertion, in which even their women join. But they especially delight in dancing; and their great favourite amusements are their national dance, the *zorcico*, and a kind of bullfight called *novillos*. Tolosa is the capital. San Sebastian as a seaport has a good trade, and gives name to the province of San Sebastian since the administrative division of 1822. The other principal towns are Fuenterabia or Fontarabia, a small fortress on the Bidassoa, close to the French frontier; Mondragon, where are rich iron mines; Salinas, on the Deva, has a salt-work (whence its name) which produces about 1000 tons per annum. La Isla de los Faisanes, an island in the Bidassoa, is celebrated as the place where the "Peace of the Pyrenees" was concluded in 1659 between France and Spain. Though the Spaniards name this island "Isle of Pheasants," yet these birds are now quite unknown there. The population of Guipuzcoa in 1849 was 141,752.

GUISBOROUGH, or Gisborough, a market-town of England, North Riding of Yorkshire, at the foot of the Cleveland Hills, not far from the mouth of the Tees, and 40 miles N. of York. It consists chiefly of one wide and handsome street, having many good houses. It has a handsome town-hall, under which the market is held; a church, a free grammar-school, and an hospital for old men and women. The first alum-works in the kingdom were established here about 1600. An Austin priory was founded here in 1129, of which some remains still exist. Market-day Tuesday. Pop. (1851) 2062.

GUISCARD, Robert (1015–1085), Duke of Apulia and Calabria, one of the most famous captains of his age, was the son of the Norman Tancred Hauterville. His life, exploits, and character, are given in great detail in chap. lvi. of Gibbon's *Decline and Fall.* See also Naples.

GUISE, a town of France, department of Aisne, on the left bank of the Oise, 13 miles N.W. of Vervins. It ranks as a fortified town of the third class, being surrounded by walls, and having a strong citadel. Pop. 3500.

GUISE, or Guyse. The family of Guise, which plays a distinguished part in certain eras of French and Scottish history, was sprung from the royal house of Lorraine. It did not become known in France till the sixteenth century, when Claude, son of René II., Duke of Lorraine, driven from home by an elder brother, entered the French army, distinguished himself on many battle-fields, and was desperately wounded at Marignan in 1515. For these services he was made Duke of Guise in Normandy and a peer of France by Francis I. He died in 1550, leaving, by his wife Antoinette de Bourbon, a large family, of which three members became especially notable. These were Marie, married to James V. of Scotland, and mother of Mary Queen of Scots; Francis, renowned as a soldier; and Charles, the Cardinal of Lorraine. For the history and character of Marie de Guise, see Scotland. Francis, surnamed "le Balafré," from a scar on his face left by a wound received at the siege of Boulogne in 1545, was the noblest of his race. He was brave, generous, and gentle-hearted, and was as able a commander as a valiant soldier. He greatly distinguished himself in the wars between France and Spain, and retook Calais from the English, almost the last relic of their ancient conquests in France. Under Francis II. his power, which in the last reign had been counterpoised by that of the Montmorencys, became almost absolute. The Calvinists and the Prince of Condé made an effort to overthrow it; but this attempt, known in history as the conspiracy of Amboise, was defeated by the vigilance of the duke. Soon after this he had himself appointed lieutenant-general of the kingdom, while the parliament voted him the title of "conservateur de la patrie." His first step was to take vengeance on the conspirators, which he did in a manner bordering on cruelty. Under Charles IX. his influence was checked, to a certain extent, by that of Condé and Coligny. The unfortunate affair at Vassi was the signal for a general war of religion in France; and shortly after the battle of Dreux (1563), in which the duke had distinguished himself, he was assassinated by Poltrot de Mérey, a Calvinist nobleman, who regarded him as the most dangerous enemy of the Reformed faith. He was succeeded in his title and estates, and the leadership of his party, by his son Henry, who, like himself, enjoyed the surname of "le Balafré." This son inherited all the talents, but few of the virtues of his father, except his courage. He seconded his uncle, the Cardinal of Lorraine, in carrying out all the schemes of the "Ligue," which, under the pretence of protecting the Catholic faith, was to serve the ulterior purpose of concentrating all the power of the kingdom in the hands of the Guises and their party. To prove his sincerity in the cause of the faith, Henri de Guise helped to carry out the massacre of St Bartholomew, planned the murder of Coligny, and hunted down the defeated Huguenots with pitiless cruelty. His successes at length made him insolent and overbearing even at court; and the king (Henri III.) forbade him ever to appear there again. Upon this the duke armed his retainers, and endeavoured to raise Paris in rebellion against its sovereign. This day, the 12th of May 1588, is famous in French history as the "Journée des Barricades." The king fled, and summoned a meeting of the states-general at Blois. He found the deputies almost all in the interest of his revolted subject, and was obliged to make the most humiliating concessions to retain even the semblance of royalty. After enduring for a few months more the insolence of his too-powerful vassal, Henry had him privately assassinated, December 23, 1588; and next day the Cardinal of Lorraine met a similar end. Even this double shock, however, was hardly sufficient to break the power of the Guises. Under Henri IV. they had recovered so far as to be able to organize the League against that prince, and did not acknowledge his allegiance until he had abjured the Protestant faith. The dukedom of Guise became extinct in 1675.

GUITAR (Span. *Guitarra*), a musical instrument much used in Spain for accompanying songs. It is supposed to be of Arabian origin, and is the last relic of instruments of the lute kind. There are different kinds of guitars—Spanish, French, and German; but the one most in use has six strings, generally tuned E, A, D, G, B, E, which chiefly belong to the bass register. Music for the guitar is written in the treble clef, though every note is an octave lower than represented. The guitar finger-board is furnished with frets, upon which the fingers of the left hand press down the strings, while these are struck by the fingers of the right hand. The Spanish and French guitars are nearly alike.

GUJERAT, a town of Hindustan, in the Punjab, about 8 miles from the right bank of the River Chenab, and 75 miles N. of the city of Lahore. The place has acquired celebrity from the victory gained in the vicinity on 21st Feb. 1849, by a British force, commanded by Lord Gough, over a Sikh army greatly superior in point of numbers, under the command of Sirdar Chuttur Singh and Rajah Shere Singh. The British, notwithstanding their numerical inferiority, gallantly attacked the Sikhs, drove them in succession from point to point, put them to disorderly flight, and captured their artillery and baggage. N. Lat. 32. 35., W. Long. 74. 8.

GUJERAT, GAJRAT, or GUZERAT, a very large province of Hindustan, comprising within its limits the dominions of the Guicowar, besides several British districts, and situated principally between the 21st and 24th degrees of N. latitude. It has been computed to be 320 miles long by about 400 broad. On the N. it is bounded by Rajpootana, S. by the Presidency of Bombay, E. by Central India, W. by Cutch and the sea. The S.W. quarter of this province is inclosed on the S.W. and N.E. by the Gulfs of Cutch and Cambay, and has the form of a peninsula. A considerable portion, particularly towards the eastern frontier, is hilly, and much covered with jungle. On the N.W. boundary, along the bank of the River Banas or Bunass, the country in some parts produces good pasture; in other parts it is either an arid plain or a low salt swamp, which, where it is dried up, is barren and unproductive. The interior is hilly and rocky; but there are spots, where water is accessible, that are extremely fertile, especially in sugar and tobacco, and which yield all sorts of grain, oats excepted; also cotton, tobacco, indigo, gum, and sugar. The country, notwithstanding its smoothness to the eye, is in many parts intersected by ravines, and much broken by the heavy rains; and some of these chasms contain, during the season of the rains, a large volume of water, not to be crossed without the assistance of rafts or boats; and, accordingly, the natives in these cases establish temporary ferries. The climate is reckoned one of the worst in India, being intensely hot during the greater part of the year, with a heavy thickness in the atmosphere, which is extremely oppressive. A hot wind blows fiercely all the day; and when it ceases at night, it is followed by a still more close and oppressive calm. "I had certainly," says Bishop Heber, "no conception that anywhere in India the month of March could offer such a furnace-like climate." "It is," he adds, "in the same latitude with Calcutta, and seems to be what Bengal would be without the glorious Ganges."[1] During the hot and dry months the surface of the country appears mostly sand or dust, and in the rainy season a thick mire. In the N.W. parts, along the banks of the River Bunass, where there is good pasturage, and in various other parts of the province, they breed excellent horses and camels; and the cattle are superior to those of any other part of India. Some of their bullocks, which are in general white, with large bumps, are sixteen hands high, and will trot in a carriage as fast, and perform as long a journey, as good horses. This province is traversed by several large rivers, namely, the Bunass, the Nerbuddah, Tuptee, Mahy, Mehindry, and Sabermatty, which, being navigable from the sea to a considerable distance up the country, afford great facilities for commerce. But there are many large tracts which experience a great scarcity of water; and the inhabitants are forced to dig wells, which are in many parts from 80 to 100 feet deep. In some particular portions of this province not a stone is to be met with, whilst in some others nothing else is to be seen.

In so extensive a province, never completely subdued by any of its numerous invaders, a great diversity of population may be expected. The population of Gujerat is accordingly very strangely diversified by numerous sects and castes, under the various designations of Grassias, Catties, Coolies, Bheels, Mewassies, Charons, Bhatts, Dheras, and others. In some parts of the province the Grassias form a numerous class of landholders, and in others they merely possess a sort of feudal authority over certain portions of land and villages. The origin of their rights is a controverted point of Hindu history, which has never been very satisfactorily explained. The common account of their title to the land is, that they were robbers and plunderers, who inhabited the hills and jungles, and by their incursions the country was so much infested, that, after the decease of the Emperor Akbar in 1605, the nabobs of Surat ceded to them certain lands in each village in lieu of all demands. But it is asserted that, encouraged by this success, they still continued their depredations; and the Zemindars, in order to purchase peace, agreed to the payment, on certain lands, of what is called *toda*, or ready money; and the lands which are liable to this payment have been continually increasing, owing to the anarchy which so long prevailed in Gujerat. The proprietors of these claims never allow them to die out; and it is seldom that they prosecute them in person, but, having retired to some secluded residence, they rally round them a band of desperate adventurers, to whom they farm out the Grassia claim, and depute them to levy it. Hence the country, prior to the war of 1817, and the consequent interference of the British government, was a prey to the greatest disorders; it was ravaged by predatory hordes, who acquired new rights, and in this manner it was plundered, and the rent of the land misappropriated. These claims have been involved in such complication and obscurity, that the British officers have found it impossible to reduce them to any accurate standard of law or justice. On the rugged margins of all rivers in Gujerat, many of these Grassias resided in a kind of independence; and also all over the Gujerat peninsula, usually denominated Cattywar by the natives. Their numbers were recruited by criminals from the plains, who fled to their haunts for refuge, and were supposed to amount to one-half of the population N. of the Mahy River. Attempts made by the Bombay government to extinguish the Grassia claims by a payment from the public treasury, and thus to prevent the disorders which they occasioned, have been crowned with success.

Of all the disorderly hordes which infested this country, the most bloody and ferocious were the Coolies. The most barbarous were those in the vicinity of the Runn, the salt morass which bounds the province on the W., and communicates with the Gulf of Cutch. These were taught to despise every approach to civilization; they are of the most filthy habits, and consider it a mark of effeminacy to wear clean clothes; and the priests and other persons of note exceed the laity in dirtiness. They consider cleanliness as indicative of cowardice. That class of men named Bhatts, or Bharotts, abound more in Gujerat than in any other province of India. They cultivate the land; but the greater part of them are recorders of births and deaths, and beggars or itinerant bards, and very frequently traders. They often stand forward as security for the public revenue, and guarantee observance of agreements and rewards. They always possess, however, an intimate knowledge of the person for whom they become security, of his character and resources; and when they find that they have been deceived, and are pressed for money for which they have become security, such is their proud and obstinate character, that they sometimes sacrifice their own lives, or some aged female or child of the family, in the presence of the person for whom they have broken their word. They form, in the rude state of society which prevails in India, a sort of middlemen between the contributors and the government; every Grassia, Coolie, and Bheel having his Bhatt, a class who are rewarded by a small percentage on the amount of the revenues for which they have become surety, and for the security which they afford against the importunity of the inferior agents of government, their persons being regarded as sacred, and their influence over the persons of the natives very great. They were chiefly employed under the Mahratta princes, between whom and the landholders they stood as middlemen, being bound to the government for the revenue, and acting as a security to the landholders against the oppressions of the government. Within the limits of British rule this agency has been discontinued, being found inefficient as an instrument of control for the unruly tribes of the country. The Charons are a sect of Hindus, allied in manners and customs to the Bhatts. They are often possessed of large droves of cattle for carriage, by means of which they carry on a distant inland traffic in grain and other articles. They also often hire themselves out as protectors of travellers in the wildest parts of the country; and so faithful are they to their charge, that when a band of predatory horse appears, these persons take an oath to die by their own hands, in case those whom they have engaged to protect are plundered; and this threat is always found effectual to restrain those superstitious thieves, who hold the Charons in great veneration. There is in Gujerat, as in other parts of Hindustan Proper, a race of people called Ungreas, whose profession is that of money-carriers, which they contrive to conceal in their quilted clothes. Although they are miserably poor, they may be trusted with large sums of money to carry many miles off, merely on the responsibility of the superior, who is frequently richer than the others. They are of all castes, and in general athletic and well armed; and they are of such singular habits, that in performing distant journeys they form themselves into parties, and fight with desperation to defend a property for which their only recompense is a mere subsistence.

---

[1] Heber, vol. iii., p. 10.

The Bheels are generally described as the original inhabitants of the country, who have been driven to their present fastnesses and their miserable way of life by the invaders of their country, whether Mohammedans or Hindus. These people were, in the first instance, treated with extreme severity by the British;[1] but in 1825 a mild and conciliatory course of policy was introduced; and they have been reclaimed from their barbarous habits and formed into regiments, subject to such discipline as was suited to their turbulent character. They also received grants of land, and freedom from taxes for a number of years; and they were in this manner trained to industrious habits.

The Dheras of this province are of a very degraded caste, and their employment is to carry filth of every description out of the roads and villages. They are miserably poor; they scrape bare the bones of every animal which dies within their limits, and share out the flesh, which they cook in various ways, and feed upon. They are obliged to serve travellers as carriers of their baggage to the village nearest their own. In the course of their business they are always committing petty thefts, and are much given to intoxication.

The Vaneeya, or the merchants and traffickers, form a numerous class in Gujerat. Many of them travel to remote parts of India, where they remain from one to ten years, after which they return to their wives and children. Many also finally settle in the towns of foreign countries, where their descendants continue to speak and write the Gujerattee tongue. The Jains are also a more numerous class here than in any of the contiguous provinces, and possess many handsome temples adorned with well-wrought images. Besides its native hordes or castes, Gujerat, along with Bombay, contains nearly all the Parsees, or fire-worshippers, to be found in the continent of India, the feeble remains of the once numerous sect of the Magi. In all the larger towns are to be found that remarkable race of men named the Boras, who, though Mohammedans in religion, are Jews in features, manners, and genius. They form a community amongst themselves, and are everywhere noted for their address in bargaining, minute thrift, and constant attention to lucre. The washermen are also considered as a degraded and cruel class, on account of the numerous deaths which they involuntarily occasion to the animalcula in the process of washing.

The province of Gujerat flourished chiefly during the era of the Mogul government, and even during the most convulsed periods it carried on a much more extensive trade than ever it has done since. The principal trade is with Bombay, and the chief exports are cotton, piece goods, and grain. The imports are chiefly sugar, raw silk, pepper, cocoa nuts, and British fabrics. Its manufacturing industry has decayed, and in general has nearly disappeared, in consequence of the greater cheapness of British wares. The principal towns in this province are Surat, Ahmedabad, Broach, Cambay, Gogo, and the Guicowars capital of Baroda. Gujerat contains populous districts, but in other parts the country is extremely desolate. Surat and the neighbouring country is thickly planted with inhabitants, and the north-western districts are equally naked and destitute of people. The country has been so much exposed to the depredations of thieves and banditti from the jungles and mountains, that, for the sake of security, the great body of the people live, not in sequestered houses, but in villages; and these villages are frequently visited by travelling companies, who exhibit puppet-shows, and histrionical representations. They are also occasionally frequented by musicians, dancing girls, singing men and women, wrestlers, expert jugglers, dancing bears, goats, and monkeys. In the remote and savage districts of the country, where there are no villages, fortifications are numerous; but in all the parts to which the British influence extends, they are fast crumbling into decay. In many parts the people are of savage and cruel manners; and amongst the tribe of Jahrejahs the practice of female infanticide prevails, and the united exertions of all the British officers and statesmen have been employed to prevent it. There is another crime peculiar to this province, known in the British courts of justice by the name of *jhansa*, which is the writing of threatening letters, the destroying of gardens or plantations, and the burning of stacks, in order to extort money, or to enforce a compliance with any other unjust demand. These offences were not formerly confined to the Grassias, but were resorted to in village feuds, even by the heads of villages. But since the regular administration of justice by the British, such disorderly practices have become less frequent. There is a class of persons, the Mahy Kaunta Coolies, who are so named from their residence on the Mahy River, who are thieves by profession, and also very ingenious, active, and courageous. They lurk on the highways, and intercept families and individuals proceeding to distant pilgrimages and religious fairs. They frequently visit Surat and other

---

[1] Heber, vol. ii., p. 496.

large cities in pursuit of their illicit occupation, though, from the increasing vigilance of the British police, their depredations are now more frequently checked. But, beyond the precincts of the British authority, in the northern and western quarters, and the centre of the Gujerat peninsula, the number of societies of armed and sanguinary thieves is scarcely credible; and it is rather surprising that even the thinly scattered population of the country should keep its ground amid the many excesses and outrages which are committed.

There are many remarkable wells and watering-places in Gujerat. One near Baroda is said to have cost nine lacks of rupees. There is another at Vadwa, in the vicinity of Cambay, which, from the inscription, appears to have been erected in 1482.

The province of Gujerat was first invaded about A.D. 1025, by Mahmood of Ghizni, who subverted the throne of its native prince, named Jamund, and plundered his capital. After the establishment of the Delhi sovereignty, Gujerat was subject for many years to the Patan conquerors. In the fifteenth century it came under the dominion of a dynasty of Rajpoot princes, converted to the Mohammedan religion, who removed the seat of government to Ahmedabad; and under their rule it flourished greatly as a maritime and commercial state. This race of princes was overthrown by the Emperor Akbar in 1572; and after the death of Aurungzebe in 1707, hordes of Mahratta depredators overran the province, which in 1724 was finally separated from the Mogul empire.

Until 1818 the Mahratta Peishwa and the Guicowar possessed large tracts of country, but at present only the last remains, the authority and dominions of the other having devolved to the British. The annual revenue of the Guicowar is estimated at L.668,744. The military establishment of this prince, in addition to his regular troops, amounting to 6000 cavalry and infantry, comprises also the subsidiary force at the disposal of the British government, which consists of five regiments of infantry, two of cavalry, and a company of artillery. He also maintains a contingent force of 3000 cavalry, and a corps of irregulars, known as the Gujerat irregular horse, commanded by British officers. In 1802 the British government negotiated with the Guicowar as a sovereign in his own right, and thus secured his independence of the Peishwa. Under the treaty then concluded the Guicowar agreed to receive a British subsidiary force. When, as a result of his first discomfiture, the Peishwa yielded to the British government his rights in Gujerat, the Guicowar received an accession of territory, and a new treaty supplemental to the former was concluded. Under this treaty the subsidiary force was to be increased by a battalion of native infantry, of not less than 1000 men, and two regiments of native cavalry. The establishment of British authority in this country experienced very serious obstructions from the intermixture of the territories ceded by the Peishwa with those of the Guicowar; also from the Nabob of Cambay, and the unsettled tributaries of Cattywar and Mahy Caunta, and still more from the lawless habits of a large proportion of the people, especially beyond the Mahy River. But, by a wise and conciliating policy, these difficulties have been surmounted, and tranquillity has gradually arisen from the confusion which at first overspread the country. (E.T.)

GULDENSTAEDT, JOHN ANTONY, a Russian traveller and naturalist of some celebrity, was born at Riga in 1745, died at St Petersburg in 1781. He took part in some of the scientific expeditions organized by the Russian government in the latter half of last century, and distinguished himself especially by his travels in the Caucasus. His memoirs on the natural history, languages, &c., of these countries, though they have been long superseded, were highly esteemed in their day, and even now possess a certain historical value. His name is associated with that of the celebrated Pallas, who after Guldenstaedt's death published an edition of part of his works.

GULES, in *Heraldry*, a corruption of the French word *gueules*, which in this science signifies *red*, and is represented in engraving by perpendicular lines. See HERALDRY.

GULF, an arm of the sea. See GEOGRAPHY.

GULF-STREAM. See ATLANTIC, vol. iv., p. 176.

GULL. See index to ORNITHOLOGY.

GUM, the hard fleshy substance which invests the teeth of either jaw. See ANATOMY.

GUM (Lat. *gummi*). This term is applicable solely to those concrete vegetable exudations which soften or dissolve in water, and afford a more or less perfect mucilage, but which are wholly insoluble in alcohol. Gums are thus distinguished from *resins*—those fusible and combustible vegetable substances which are totally insoluble in water, but which soften and dissolve in ether, essential oils, and alcohol. Gum, properly so called, is used in large quantities for a number of purposes in the arts. There are six varieties of this substance, viz., gum-arabic, gum-senegal, cherry-tree gum, with that of other stone-fruit trees, gum-tragacanth, gum of Bassora, or Bazrah, and that extracted from seeds and roots by boiling water.

Gum-arabic is the purest of these, and consists almost entirely of the principle called *arabine*. It forms a clear mucilage with water, and is clearer, and keeps better if dissolved in cold water than when prepared with warm water, which is the common method. Gum-arabic is the produce of several species of *Acacia;* as *tortilis, seval, Ehrenbergii, vera, arabica.* One hundred parts of good gum were found to consist of 70·40 of arabine, 17·60 of water, and a few per cent. of saline and earthy matters.

The method of collecting this gum as practised in Morocco may be briefly described:—About the middle of November, that is, after the rainy season, a gummy juice exudes spontaneously from the trunk and principal branches of the acacia-tree. In about fifteen days it thickens in the furrow, down which it ran either in a vermicular form, or, more commonly, in the shape of oval and round tears, about the size of a pigeon's egg, and of different shades of colour as they belong to the white or red gum-tree. About the middle of December the Moors encamp on the border of the forest, and commence the harvest, which lasts six weeks. The gum is packed in very large bags of leather, and brought on the backs of bullocks and camels to certain ports, where it is sold to French and English merchants. It is highly nutritious. During the whole time of harvest, of the journey, and of the fair, the Moors of the desert live almost entirely upon it; and experience proves that six ounces of gum taken during the twenty-four hours are sufficient to support a man for a considerable period.

The quantity of gum-arabic imported into Britain in 1852 amounted to 48,484 cwts.; that of gum-senegal to 4267 cwts.; of tragacanth, 1151 cwts. Previously to the year 1832, the duty on gum-arabic from a British possession was 6s. a cwt., and from other parts, 12s.; but the duty on all gums, from whatever part of the world, was then equalized, being fixed at 6s.; in 1841 it was further reduced to 1s.; and it was finally repealed in 1845. Of the 48,484 cwts. of gum-arabic imported in 1852, Egypt produced 16,414 cwts.; Morocco, 7131; Italy, 3952; East Indies, 16,089; other countries, 4898.

Gum-senegal is also a very pure gum, much resembling gum-arabic, and is applied to many of the same purposes as that of gum. It is also much employed in calico-printing. The tree which yields it is the *Acacia senegal*, so named from the country of the River Senegal in Africa, whence this gum is procured. Its constituents are arabine 81·10, water 16·10, with 2 or 3 parts of saline matters.

Cherry-tree gum is an inferior and less soluble kind of gum, containing 54·90 parts of cerasine, 52·10 of arabine, 12 of water, and 1 of saline matter.

Gum-tragacanth, familiarly called *gum-dragon*, is the produce of several species of *Astralagus*, but more particularly of *A. verus* and *A. gummifer;* the former a native of the north of Persia, Armenia, and Asia Minor, and the latter of Mount Lebanon, Arabia, &c. These at least are the chief sources of the tragacanth met with in commerce. It is likewise yielded, though less abundantly, by *A. creticus* and *A. aristatus*, and some other species. It is imported in twisted thread-like pieces, or in flattened cakes, is of a whitish or yellowish colour, devoid of taste and smell, nearly opaque, and a little ductile. It swells in water, and dissolves in part, forming a very thick mucilage. One hundred parts of it consist of 53·30 arabine, 33·30 bassorine and starch, 11·0 water, and from 2 to 3 parts of saline matters. It is used in medicine as a demulcent, and to form lozenges and pills, &c. It is also employed to stiffen and to glaze silks; and the inferior kinds are used by shoemakers to finish off the edges of their work.

Gum of Bassora, or that brought from Bassora in Arabia, possesses most of the properties of tragacanth, and gives its name to the principle called *bassorine*, which forms a constituent part of this gum and of tragacanth.

Gum from roots and seeds is extracted by boiling water. Linseed, for example, yields, by boiling, a gum consisting of 52·70 arabine, 28·9 insoluble matter, 10·3 water, and 7·11 saline matter.

The substance called *British gum*, so largely used in calico-printing, is noticed under the head British Gum.

Gum-Resin. This term is applied to an inspissated juice afforded by many kinds of plants, which combines the properties of gums and resins, being partly soluble in water, partly in alcohol. The principal gum-resins are aloes, ammoniac, assafœtida, galbanum, gamboge, euphorbium, olibanum, scammony, besides a great variety of other concrete juices. The chief of these are noticed under their respective names, as also the resins properly so called.

GUMBINNEN, a town of Prussia, province of East Prussia, and capital of a government of the same name, on the Pissa, 70 miles E.S.E. of Königsberg. The town is well built, with spacious and regular streets, and fine promenades, shaded by linden trees. It is the seat of the different governmental courts, and has a gymnasium, schools of architecture and midwifery, a public library, and an hospital. It has manufactures of woollen and linen stuffs, leather, and brandy; and some trade in corn. Gumbinnen was only a small village till 1732, when it was improved and made a town by Frederick William I., to whom a statue was erected in the market-place in 1832. Many Protestant families from Salzburg, driven from their homes, settled here and contributed to its rise and prosperity. Pop. (1849) 6794. The government of Gumbinnen has an area of 6312 English square miles, and is almost one continued flat, extensively covered with lakes. The cultivated land is fertile, but a large portion of this government is densely wooded, or covered with heath and morass. The chief products are wheat, rye, flax, and hemp; and cattle and sheep are numerous. Pop. (1849) 614,047, of whom 601,016 are Protestants.

GUMPELTZHAIMER, Adam, a musician, born at Trosberg, in Bavaria, in 1560. The year of his death is not known. In 1581 he was appointed *cantor* of the school of Augsburg. He merits historical notice as one of the early creators of that German style of harmony which was afterwards employed with such effect by Handel, J. S. Bach, and others. "His modulations," says an eminent critic, "were based on the modern system of tonality; and while they were lively and unexpected, were still smooth and natural." There are several published collections of his *Spiritual Songs for Four Voices.*

GUN. See Gun-making, and Rifle.

GUN-COTTON. Cotton is one of the numerous forms of lignine, a compound of carbon, oxygen, and hydrogen; but when it is subjected to the action of nitric acid, nitrogen, which exists in most explosive bodies, enters into its composition. The action of nitric acid on lignine had long attracted the attention of chemists; but the nearest approach to the formation of gun-cotton was made by Pelouze, who, in 1838, writes in the *Comptes Rendus* of the properties of a substance named *Xyloidine*, from ξυλον, wood, discovered by Braconnet in 1833:—"It is very combustible, taking fire at 356° Fahr., burning with great rapidity; and almost without residue. This property has led me to an experiment, which I think susceptible of some application, especially in artillery. By plunging paper in nitric acid of sp. gr. 1·5, leaving it there the requisite time for the acid to permeate the paper, which is usually accomplished in two or three minutes, then withdrawing it, and, lastly, washing it in water, we obtain a kind of parchment impermeable to moisture, and extremely combustible." In 1846, Schönbein exhibited to the British Association at Southampton specimens of cotton, which appeared to be as explosive as gunpowder; but it was not till April 1847, on the enrolment of the patent, that the method of preparing this cotton was known, although, in the interval, Otto of Brunswick, Morel of Paris, and Böttger of Frankfort, published recipes for making explosive cotton. Schönbein's method consisted in mixing three parts of sulphuric acid, sp. gr. 1·85, with one part of nitric acid, sp. gr. 1·45 to 1·50; and when the mixture had cooled down to between 50° and 60° Fahr., clean rough cotton in as open a state as possible was immersed in the acid; when well soaked, the excess of acid was drawn or poured off, and the cotton pressed lightly in order to separate the principal portion of the acid. The cotton was then covered over and left for half an hour, when it was pressed and thoroughly washed in running water to get rid of all free acid. After being partially dried by pressure, it was washed in an alkaline solution made by dissolving one ounce of carbonate of potash in a gallon of water. The free acid being thus got rid of, it was put into a press, the excess of alkaline solution was expelled, and the cotton left nearly dry. It was then washed in a solution of pure nitrate of potash, one ounce to the gallon, and being again pressed, was dried at a temperature of from 150° to 170°. It was stated, that three parts of the gun-cotton thus prepared were equal in force to eight parts of Tower-proof gunpowder.

Cotton gains considerably in weight by the above treatment, but it is scarcely changed in colour or in general appearance, if the process has been carefully conducted: it is, however, harsh to the touch, and gives a crepitating sound when pressed by the hand. It differs from common cotton by its electric excitability, the slightest degree of friction causing it to be powerfully attracted and repelled by other bodies; and also by its action on a ray of polarized light, which it does not depolarize like ordinary cotton. It explodes at a temperature of from 350° to 400°, with such rapidity as to interfere with its practical application, for if applied to the purposes of artillery, it may burst the gun before it has time to move the shot, and some of the products of its combustion make it also objectionable for fire-arms. Among these products water may be mentioned, and, should the cotton not have been well washed, nitrous acid. Another great impediment to the use of gun-cotton is its hygrometric condition, for if exposed to a damp atmosphere, it will in an hour or two absorb a considerable portion of moisture. Many attempts have been made to apply it to mining purposes on account of its enormous force, and the small quantity of smoke which it produces; but the objections to its use are numerous, the most fatal objection being its liability to spontaneous ignition.

Nevertheless, gun-cotton continues to be an object of great interest on account of its application to the beautiful art of photography. When the cotton is prepared in such a way as to burn slowly, it is not liable to spontaneous ignition, and in this state it is perfectly soluble in sulphuric ether, which the more explosive cotton is not. If the ethereal solution, called *collodion*, be poured on the surface of cold water, a paper is produced, which is prepared for the use of the photographer. This paper is a very active electric, and is perfectly soluble in ether. Collodion has also been made use of in surgery, by applying the ethereal solution to a wound, when a thin delicate artificial skin is formed by it, which perfectly excludes the air.

In the preparation of gun-cotton, nitric acid is the active agent in the formation of xyloidine: the sulphuric acid has no direct action on the lignine, its use being to retain the water abstracted from the cotton, and prevent the solution of the compound which takes place to a greater or less extent in nitric acid alone. The purity and exact strength of the acids are matters of great importance. Mr Hadow found that the best mixture for producing collodion wool is obtained by mixing 89 parts by weight of nitric acid, sp. gr. 1·424, with 104 parts by weight of sulphuric acid, sp. gr. 1·833.

On trying the effect of various re-agents on gun-cotton, Mr Hadow found that it could be perfectly restored to the original cotton, without loss of form, by means of an alcoholic solution of hydro-sulphuret of potassium. On this, and other points connected with the chemistry of gun-cotton, we must refer to Mr Hadow's paper, published in the *Transactions of the Chemical Society*. (C. T.)

GUNDAMUK, a walled village of Afghanistan, on the road from Jelalabad to Cabool, 28 miles W. of the former. Here, on its retreat from Cabool, in 1842, the remains of the British force, amounting to about 100 soldiers and 300 camp followers, were massacred, and only one man escaped.

GUNDUCK, a large river of Hindustan, flowing from the Himalaya Mountains, and falling into the Ganges. Its source is presumed to be in the territories of a native chief, named the Moostang Rajah, now tributary to the Rajah of Nepaul. After a course of about 200 miles, it sweeps round the base of the Maddar Mountain, where the river is perfectly clear, and broader than the Thames at Chelsea, with banks of abrupt rocks alternating with levels covered with stately forests. In the upper part of its course the river is called Salgrami, from a curious species of stones found in its bed and held sacred by the inhabitants. They are mostly round, and perforated in one or more places with worms, which the Hindus, in their degraded superstition, believe to have been done by Vishnu in the form of that reptile; and the stones are prized in proportion to the number of perforations or spiral curves in each. These stones are called Salgrams. A few grains of gold are occasionally separated from the sand of the Gunduck. From the Maddar Mountain the course of the river is in a south-easterly direction for the further distance of 200 miles, when it falls into the Ganges, at the town of Hajeepoor, opposite the city of Patna, in N. Lat. 25. 39., W. Long. 85. 16.

GUNDWANA, a large province of Hindustan, in the Deccan, extending from the 19th to the 25th degree of N. latitude. The tract may be considered as comprising part of the British territory of Saugor and Nerbudda with the districts of Singrowlee, Chota Nagpore, and Sirgooja, the petty native states on the S.W. frontier of Bengal, the Cuttack Mehals and the northern portion of Nagpore. It is estimated to be 400 miles in length, by 280 in average breadth. Gundwana, in its most extensive sense, includes all that part of India within the above-mentioned boundaries which remained unconquered by the Mohammedans up to the reign of Aurungzebe. But Gundwana proper is limited to four districts, named Gurrah-Mundela, Choteesgur, Nagpore, and Chandah, and it stretches S. along the E. side of the Wurda and Godavery, to within 100 miles of the mouth of the latter. The greater part of this province is a mountainous, unhealthy, and ill-watered country, covered with jungle, and thinly inhabited; and to its poverty and other bad qualities its independence may be ascribed. A continued chain of moderately elevated hills extends from the southern frontier of Bengal almost to the Godavery, and by these the eastern was formerly separated from the western portion of the Nagpore dominions. This province contains the sources of the Nerbudda and the Soane, and is bounded by the Wurda and Godavery; but a want of water is still the general defect, the streams by which it is intersected, namely, the Mahanuddy, Caroon, Hatsoo, and Silair, being inconsiderable, and not navigable within its limits. The Goands, or the hill tribes, who took refuge in the mountains and fastnesses from the invaders of the country, are the original inhabitants of the country, and still retain all their primeval habits of barbarism. The country which they inhabit is a mere wilderness, its inhabitants scarcely rising above the level of beasts. Their habits are loose and disorderly, and they frequently descend from the mountains which they inhabit to plunder the plains below, from which they were originally driven. In the course of the last century they have acquired an increasing appetite for salt and sugar, and the desire to procure these articles has operated as a stimulus to their industry, and tended more than any other circumstance to promote civilization amongst them. These Goands are Hindus of the Brahminical sect; but they retain many of their impure customs, and abstain from no flesh except that of the ox, cow, and bull. The more fertile tracts of Gundwana were subdued at an early period by the Bhoonsla Mahrattas, who claimed as paramount over the whole. The inhabitants were rendered nominally tributary; but it was found impossible to collect any revenue from them without a detachment, so that in fact the collection of the revenue was rather like a plundering expedition, the cost of which always exceeded the profit. During the war against the Pindarees in 1818, when the British troops invaded the territories of Appa Saheb, the Rajah of Nagpore, their operations were greatly facilitated by the insurrection of the hill tribes, who occupied the passes into the Nagpore territories. For a long series of years it was the policy of the rajah of this territory, a descendant of Sevajee, to interfere as little as possible with the neighbouring powers. At length, in 1803, Ragojee Bhoonsla was induced, in an evil hour for himself, to depart from this system of neutrality, and to join Scindia in a confederacy against the British. He was soon reduced, however, by the defeats which the confederates sustained at Assye and Argaun, to sue for peace, as the price of which he ceded a large portion of his dominions to the conquerors, namely, the province of Cuttack, including the pergunnah and port of Balasore. After the death of this rajah, whose sole object seemed to be to amass treasure, and who, for this purpose, laid the country under heavy contributions, and even joined with the Pindaree plunderers, the throne, contested by various competitors, was at last secured by Appa Saheb, his nephew, who, in the war against the Pindarees, joined the coalition against the British power, and was involved in ruin along with his other allies. A treaty of peace was concluded with him, which he violated; and he was finally deposed in 1818, and the grandson of the late rajah put in his stead. The latter prince, after a reign of 35 years, died in 1853; and leaving no issue, the dynasty became extinct, and the kingdom of Nagpore was incorporated with the British empire. (E. T.)

GUN-MAKING.

The term gun-making is applied to the manufacture of small arms generally—including the fowling-piece, the musket, the rifle, and the pistol. The rifle, being an arm of peculiar construction, and having properties distinct from those of other fire-arms, is treated separately. (See Rifle.)

The parts of a gun are the barrel, the lock, the stock, and the furniture.

1. *Of Barrels.*—Gun-barrels being made for various purposes and for different classes of purchasers (some of whom are willing to pay the highest price for the most perfect weapon, while others desire the cheapest article), vary considerably in the quality of their material, the mode of their construction, and the amount of labour expended on them. The material is in general iron, but steel is used to some extent in the preparation of the best and highest-priced barrels for sporting guns, and also, in the form of cast-steel, for a new species of rifle-barrel that has been used in America with the greatest success, and which recently has been introduced into this country both at Birmingham and Glasgow.

In the selection of iron for barrel-making, two qualities are absolutely essential—tenacity and elasticity. The first that the barrel may not burst under the explosive action of the powder, which does not expand gradually, but strikes suddenly like a hammer; the second that the barrel may not bulge, and also that it may preserve a certain sharpness of reaction requisite for the good shooting of the piece. It is therefore of the first importance that the iron should be of the best description that can be procured. Common iron, such as is used for the heavier works of ordinary manufacture, is so large and loose in the grain, that it could not stand the shock of explosion; and the gun-barrel makers from an early period have made strenuous endeavours to improve the quality of the metal, which in their hands has been brought to a higher state of perfection than in any other art. The finest iron ever used in this or any other country has probably been produced by the gun-makers in their attempts to work the metal up to its limits of excellence. The more iron is drawn out and forged under the hammer the more its quality improves, provided it is not burnt; and this circumstance induced barrel-makers to select the materials that had already undergone the utmost amount of work by fire and anvil. Hence arose the manufacture of gun-barrels from *stubs* or horse-shoe nails, which were not only made from rods of the best iron, but heated and hammered into their peculiar form, and afterwards *cold-hammered* to render them smooth, and to give the turn to the point which brings the nail out of the hoof. The *stub* was therefore the article that had most hammering expended on it, and was the best material for the manufacture of gun-barrels. So great was the superiority of the iron, that since stubs have ceased to be employed—either from the scarcity of the nails, or from the fact that inferior metal was employed in their manufacture—the efforts of barrel-makers have been directed to the production of an iron that should equal the stub; it being considered the standard of excellence to which all iron employed for good barrels should be made to approach more or less nearly. The barrels of the best sporting guns are now made of a mixture of iron and steel, which passes under the name of *laminated steel.* These barrels are of excellent quality, and shoot better than iron barrels on account of the elasticity of the metal.

When the iron is selected, whether of ordinary or superior quality, it is clipped by a pair of shears worked by steam into pieces the size of stubs. These are then washed to remove dirt, and cleansed in dilute acid to remove rust. They are then placed in a drum which revolves rapidly on a shaft, and the pieces are rolled and tumbled over each other till they become as bright as silver. They are now carried to the air-furnace, where they are heated almost to a state of fusion, so that they adhere together into a ball called a bloom of iron. From the furnace the ball, weighing about 40 lbs., passes to the forge-hammer, where it is drawn into a bar; and the bar then passes to the rolling-mill, where it is reduced to the requisite size for the manufacture of the barrels.

Iron barrels in Britain being made exclusively at Birmingham, we describe the process as at present practised by the Birmingham forgers. When the forge fire is first lighted it will not make what are termed best barrels. It requires to be burning and at work for several hours before it comes into working order for the fine twist barrels, and consequently the men begin by welding a number of the commonest and cheapest barrels. To each fire there are three men, the foreman and two assistants. They begin by making *rolled* barrels, which are the simplest in construction and most common in quality. A rolled barrel is merely a strip of iron folded up lengthwise like a boy's pea-shooter, and welded along the joint. The fore-part of the barrel, however, being required of less thickness than the breech end, these barrels are usually made of two lengths or tubes. The strips or plates of iron are heated and beat in a groove until they form a tube half closed. They are then heated again and closed with the edges overlapping. The edges are then welded on a mandril, and when a certain number of pieces are prepared the men proceed to weld together the two pieces of each barrel. The end of the breech part is opened a little on the beam of the anvil, the end of the fore-part is introduced, and the joint completed.

The fire being in proper order for the finer kinds of work, the welders proceed to forge twisted barrels, which differ from plain barrels in the circumstance that the grain of the iron, instead of running longitudinally, runs diagonally across or round the barrel, making a more perfect, stronger, and safer tube, neither so liable to burst nor to bulge. If we take a strip of paper half-an-inch broad and roll it diagonally round a ruler, we have a representation of the construction of a twisted barrel; and the joint that is welded, instead of being straight from end to end of the piece, is a spiral that makes a certain number of turns, according to the breadth of the rod of iron employed in the process. For the finest barrels the rod is nearly square, being $\frac{6}{16}$ths of an inch in breadth, and $\frac{5}{16}$ths in thickness. For very common barrels the rod is rather a ribbon of iron, being an inch or more in breadth. The latter will make only six turns in six inches of length, the former will make about fifteen or sixteen turns in six inches. The one makes a diagonal or open twist, the other a transverse or close twist; and in general the quality of a barrel may be ascertained by observing whether the twist be close or open, as only the best materials and the best workmanship are employed on the closest twisted guns.

The welders now take a rod four feet long and turn it into the form of a corkscrew (except that the turns lie close together), by means of two iron bars, one fixed and the other loose, the loose bar having a notch to receive the end of the rod. When inserted, the bar is turned by a handle until the whole of the rod is twisted, leaving a short end on which to weld a new rod. A sufficient number of pieces being prepared, the piece intended for the breech end is heated to a welding heat for about three inches, and *jumped* close by striking the end on the anvil. It is then hammered in a groove to make it round. One piece being welded, another is joined on by a single stroke of the hammer. The process continues till the barrel is of the required length, when it is again heated, a mandril introduced, and the tube is hammered in a groove. When cold, it ought to be cold-hammered to condense the iron and give the close grain that produces elasticity.

A patent has recently been taken out for making twisted barrels by machinery. A strip or ribbon of iron is first taken, bevelled at the edges, and slightly concave on the under side. This strip of metal is coiled round a mandril and welded at one heat, and the process combines rapidity with economy. Best barrels, however, are still made by the hand-hammer.

The plain barrel and the twisted barrel are those most commonly in use—the former for military and export purposes, the latter for sporting purposes. But another kind of barrel is made, being a combination of both. This is called the plated barrel, and is used for heavy rifles. Twisted iron being dearer than plain iron, the plated barrel has only a thin ribbon of twist rolled round a plain tube. If well made it is quite safe, and is perhaps as good for a rifle as if the twist were through the whole thickness of the metal; but it is to some extent an imposition, at least when sold as a genuine twisted barrel.

The Damascus barrel, so attractive from its handsome appearance, is made of iron and steel. Alternate bars of iron and steel are placed on each other in numbers of six each, after which they are rolled into rods $\frac{3}{8}$ths of an inch square. The rods are heated throughout their whole length, and the two ends put into the heads of a description of lathe worked by a handle. It is then twisted like a rope, or, as Colonel Hawker says, wrung as wet clothes are. Three of the rods are then placed together, and welded with the twists or figures running in opposite directions, and from these rods the barrel is welded in the same manner as a twist barrel. The Damascus barrel is beautiful in figure, and shoots well, but is greatly inferior in strength to the stub or best iron barrel. It is much used on the Continent for double rifles and for the double guns with one barrel rifled, but in Britain it has ceased to be esteemed, except for a few fancy articles.

Boring of Barrels.—When a barrel is forged and welded it is taken to the boring-bench and secured on a sort of carriage that can travel the requisite length. A boring-bit of suitable size is fixed into a revolving spindle, and the point introduced into the end of the barrel. The bit is worked by steam, water, or hand, and is pressed forward by a weight until it has passed through the tube. During this operation a stream of water plays on the barrel to keep it cool. Bits of larger size are then used till all the blacks and scales are bored out, and the tube rendered of the proper calibre. (See BORING).

From the boring-bench it passes to the grindstone. The stones are of very large size, and revolve at a terrific rate; and the workmen have a method of allowing the barrel to turn in their hands at half the rate of the stone. By this means they produce a fine surface, and remarkable accuracy of form. Best barrels are turned after being ground; inferior barrels are struck up with a large smooth or fine cut file. They are then tapped in a temporary way, the proof-plug screwed in, and in that form they are sent to the proof-house. The London proof-house, however, requires the barrels to be fitted with their permanent breeches, and double barrels to be soldered together.

When barrels are turned they are fixed in the lathe—usually self-acting—by means of plugs or mandrils, made perfectly true, and of various diameters, to fit different bores. These are placed on the centres of the lathe, and a carrier is fastened on the plug that projects from the breech end of the barrel. The leading screw that travels the slide-rest is then set at the angle to which the barrel is to be turned, and the tool proceeds until the whole exterior of the tube is finished.

The next process is breeching, of which there are three kinds—common-plug breeching, chamber-plug or mortar breeching, and patent breeching. The first is used for the plainest and cheapest guns. The second is a slight improvement on the first, and consists in making a small ante-chamber in the body of the plug, so that the grains composing the main body of the charge of powder may be ignited simultaneously. These breeches are neither so convenient, nor do they generate as much force as the patent breech. They are screwed to the stock instead of being hooked to the break-off, and consequently the barrel cannot be removed from the stock without considerable trouble. The patent breech, the invention of Mr Henry Nock, is one of the greatest improvements ever made in fire-arms, and is the only form of breeching suitable for fowling-pieces and other guns of a superior description. Its great advantage is its superior strength and neatness; and the circumstance that the touch-hole, whether for a flint or percussion gun, passes into the solid breech, and not through the breeching-screws. It also permits the barrel to be removed from the stock by the sliding of a single bolt, which can be withdrawn by the finger.

Double Barrels.—Double barrels are made of two single barrels, flattened a little by the file on one side, and soldered together, with a rib on the top-side, along which aim is taken, and a rib on the under-side, to which the pipes for the ramrod are attached. Some makers have had a practice of *brazing* the breech-ends of double guns for about five or six inches; but this practice is altogether to be condemned, as the heat required for brazing is so great that it softens the metal, and deprives it of the elasticity and density produced by hammer-hardening. The other portion of the jointing being effected by soft solder, there is also a danger that the solder does not come perfectly up to the brazed portion, and that the barrels may rust away in a place that is out of sight, and perhaps may ultimately burst in consequence of the defect. The patent breeching of a double gun is an extremely ingenious piece of work. The breech of the left barrel, after being tapped, is screwed into its place, and a cutting tool with a directing plug is introduced into the right barrel. The tool is then turned either by a lathe or brace, and removes the metal so as to form the concave breech. The other breech is then turned to the exact size, and forms the cylindrical or convex breech.

The Proof of Barrels.—Whatever care may have been taken in the forging of barrels, it is requisite that they should undergo a proof before use, as defects may exist which are imperceptible to the eye. This is done under the authority of the government—an act of parliament having been passed in 1813, and another in 1815, to insure the efficient proving of barrels, and to inflict penalties on any maker who should "rib, stock, or finish a barrel that has not been duly proved." The proof-houses are situated at London and Birmingham, and to these two establishments all barrels must be sent, with the exception of those belonging to the East India Company, which has a proof-house of its own in London. A recent and most judicious regulation requires that barrels should be proved a second time, *when percussioned*, as serious accidents are supposed to have arisen from makers reducing the barrels by reboring them after they had been proved and stamped. The proof consists in firing the barrels with a very heavy charge of powder, over which is a wadding of paper, then a leaden ball to fit the bore, then another wadding of paper. If the barrels burst, bulge, or exhibit any perceptible flaw, they are at once rejected; if not, they are washed in the water, impregnated with saltpetre, in which former barrels have been washed. They then stand for a day, and cracks or fissures become apparent by the saltpetre crystallizing on the defective weld. The Birmingham makers have an ingenious plan of filing out a crack, and hammering in a piece of wire to conceal the defect, and such barrels are sold at a lower price.

The following table exhibits the proof charges of powder for the respective calibres:—

The powder used is the best round granulated government powder.

Gun Locks.—Next in importance to the barrel of the gun is the lock, which has undergone many successive improvements, and has now arrived at a state of remarkable excellence and efficiency. It commenced as the matchlock, still used by some of the eastern nations, was improved into the wheel-lock, which generated sparks by the revolution of a notched wheel of steel, then became the snaphance, which is the foundation of the common flint-lock, was then changed into the ordinary flint-lock, with a single hammer and pan; and finally has resulted in the percussion-lock, which ignites the charge by means of a copper cap, containing detonating powder. The percussion-lock has so completely superseded the flint that the latter may be termed antiquated; and, though still used, is no longer manufactured. It is unnecessary, therefore, to describe more than the percussion-lock. The merit of applying detonating powder as a substitute for flint in the discharge of firearms belongs to the Rev. Mr Forsyth, minister of Belhelvie, a parish in Aberdeenshire. Fig. 1 is a representation of the original percussion-lock. It is ingenious; and if it would work with safety and efficiency, would be even preferable to the lock used in the present day; but it is unsound, and liable to accidents. It has a magazine, *a*, for containing the detonating powder. This magazine revolves round a roller, *b*, the end of which is screwed into the breech of the barrel. A small hole is opened in the roller, through which the priming-powder passes. This hole communicates with a channel which leads to the chamber of the gun. Right above the little hole in the roller is the pan for containing the priming. The magazine is provided with a steel punch, the under end of which is right above the pan, ready to ignite the priming when struck on the upper end by the cock, *d*, in firing the gun. When the punch is struck down into the pan it is raised up again to its former position by a spiral spring. Every time the gun is fired the magazine is turned round, so as to drop a priming of detonating powder into the pan. It is then turned back again, and the steel punch is found in the position ready to fire the gun when the trigger is drawn. The defect of this lock was, that the magazine containing the detonating powder was apt to explode; but if the principle could be carried out with safety it would form a self-priming lock—a great desideratum both for military and sporting purposes.

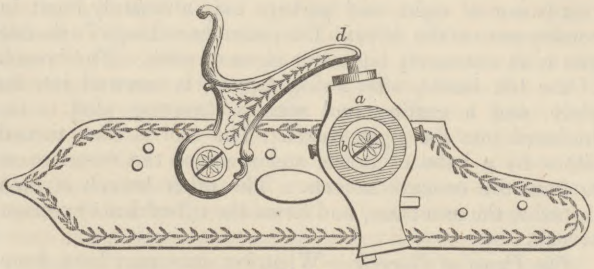

Fig. 1.

Another form of lock, called the tube-lock, fired the charge by means of a tube containing detonating powder introduced into the side of the breech. Another form was the patch-lock, which gave fire by means of a patch of detonating powder on the face of the hammer. Another form, used in America, gave fire by means of a small globe of detonating powder crushed into the touch-hole, and struck by a steel point. All these forms, however, have given way to the copper cap, which appears to have the suffrages of all the best gun-makers. Other forms must at present be regarded rather as fancy articles than as belonging to ordinary gun-making.

Fig. 2 represents one of the best British locks, as received by the gun-maker from the lock-maker—the hammer being afterwards supplied by the former in making up the gun.

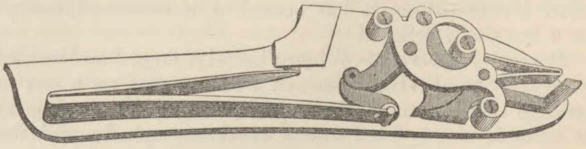

Fig. 2.

Fig. 3 represents the separate pieces of the same lock, technically called the *works*. A, the lock-plate; B, the

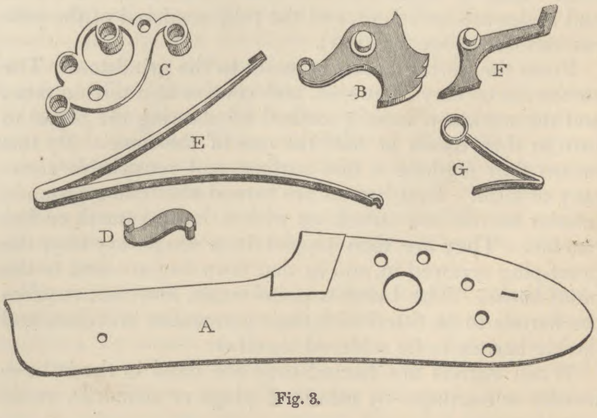

Fig. 3.

tumbler; C, the bridle; D, the swivel; E, the main-spring; F, the scear, on the projecting branch of which the trigger acts; G, the scear-spring, which resists the pull of the finger, and keeps the scear in the notch of half-bend or full-bend. Fig. 2 represents the pieces in position when the hammer is down. This is termed a *bar*-lock, on account of its being fitted under a projecting bar at the breech end of the barrel. The works, however, may be partially reversed so as to place the lock in the hand of the stock, in which case the lock is termed *back-actioned.* The back-actioned lock was popular some years since; but the general opinion of makers and sportsmen seems to have decided so completely in favour of the bar-lock, that no other is now made in the ordinary way of business.

Very common locks, such as those applied to the old muskets, were made with a hook instead of a swivel. Such locks have a dull, heavy action, and never work with the lively motion of the swivel-locks. The swivel, although apparently a mere means of connecting the main-spring with the tumbler, is a very important part of the mechanism. If well hung, it has the effect of making the heaviest pull or greatest force of the main-spring—not when the hammer is on full-bend, as might be supposed from the circumstance that the more a spring is bent the greater its force—but when the hammer is down on the nipple. This, in fact, is one of the principal tests of a well-made lock; and an experienced finger will at once detect a bad lock, from the mere circumstance that the pull increases instead of decreases as the hammer is drawn up. For military purposes it has not been customary to use the swivel-lock, except for the most recently-made rifles; but it is poor economy on the part of the government to arm a soldier with an inferior weapon, when the extra cost would not amount to more than a couple of shillings for each musket or rifle.

Some locks, especially those intended for rifles where a hair-trigger is used, have a *detant*—that is, a small piece of moveable steel attached to the tumbler in such a way that when the lock is on half-bend the detant lies behind the point of the scear. When the lock is on full-bend the detant lies in front of the scear, and projects beyond the half-bend notch, so as to carry the scear clear of the notch even if there be no pressure on the trigger. With a detant the lock cannot be let down from full to half-bend without being let down past the notch, and drawn up again—an advantage which insures that the scear shall be securely inserted into its proper place, and shall not hang on the edge of the notch, where it might slip and produce accidents. The detant is not generally used for sporting fowling-pieces, but it has advantages even for those guns.

Many safety-locks have been invented, in the hope of obviating the distressing accidents caused by the improper use of fire-arms, but not one has ever obtained the approbation of the mass of sportsmen or gun-makers. The true safety-lock is *caution.* Habitual caution in the use of arms is preferable to any mechanical device, which, while inefficient in the hands of a careless bungler, has the additional disadvantage of inducing the want of caution. All sorts of complicated devices are to be avoided in fire-arms. Those who use them must learn that the only security from accident is the most careful and constant prudence, and the habitual conviction that caution must never be relaxed. The practice of *caution* can be acquired by attention, and it is one of the first requisites of all who handle arms. A ship of war, for instance, is filled with the most tremendous materials of destruction, yet very few accidents occur, even in the gigantic navy of Great Britain. The reason is that one and all are taught *habitual caution*—systematic prudence reduced to one of the ordinary rules of life. So it should be with the sportsman; and no man ought to be trusted with arms who cannot acquire an intelligent and vigilant habit of using his weapon with careful prudence. What are termed self-acting *safeties* are, in general, devices, not for obviating accidents, but for extending the reputation or traffic of the inventor. A common bolt, however, which can be moved by the finger, and which checks the lock by bolting into the back of the tumbler, is a simple and useful appliance, and might be more generally used. In crossing a fence, jumping a ditch, or passing through a hedge—the occasions on which accidents frequently occur—the bolt prevents the discharge of the gun. Sportsmen do not generally use the bolt, except to rifles. In this perhaps they err, as it may safely be affirmed that bolt-locks would have prevented many of those accidents caused by twigs catching the triggers, or by some impediment coming in contact with the hammers that have improperly been left down on the caps, when, if they are not forced up to the half-bend, the gun is fired, and perhaps a catastrophe takes place. The disadvantage of the bolt is, that if the sportsman neglect to unbolt his lock, and a bird rises, he pulls hard, and risks breaking the scear. On the whole, however, the balance is in favour of the bolt, which is the only safety appliance that can be thoroughly recommended for general use. At the same time it is quite possible that a simple safety-lock may yet be devised; and, perhaps, this desideratum may be found in some method of locking the trigger in such a manner that the check shall be relieved at the moment of firing. There have been plans of this kind, but too complicated for general use.

The trigger, although not a constituent portion of the lock, is connected with the lock mechanism. The plain trigger is merely a piece of iron or steel hung upon a pin so as to press up the branch of the scear and relieve the tumbler. The introduction of a slight spring called the trigger-spring was one of the refinements which have now brought the best British guns up to such an admirable state of perfection. This spring prevents the triggers from hanging loose or rattling, and it brings them forward to the finger. Much of the excellence of a fowling-piece depends on the manner in which the triggers are hung.

The hair-trigger, used for pistols and rifles, is a construction by itself, and when well made is a remarkably neat piece of mechanism. Its object is to discharge the gun with the slightest possible pressure of the finger on the trigger. It can be made to any degree of fineness, and is called a *hair*-trigger, because, when finely set, a single hair will discharge the piece. It is then, of course, dangerous, as a jar or shake might produce an accident. It requires the most careful manipulation, and at all times is rather a critical appendage to fire-arms. Above all, it requires to be well made, an inferior hair-trigger being positively worthless. No part of a gun requires more perfect materials and workmanship, and therefore every purchaser of a weapon fitted with a hair-trigger should make sure that it is a good one. There can be no doubt that the hair-trigger is an advantage for rifle-shooting, where extreme accuracy is required, and where the pull on the common trigger is apt to diverge the gun from the line of aim, but it is so delicate in action that it can only be used safely in experienced hands. The principle of a hair-trigger is to make a spring do the work of the finger—the spring being set beforehand, so that when we wish to fire we have only to detach the spring and it strikes up the scear. When we fire a gun we do not take a hammer in our hand and strike the percussion-cap; we draw up the hammer of the lock to full-bend, and the main-spring exerts the required force. And so with the hair-trigger, we first set its spring, and when we wish to fire, the spring relieves the tumbler and discharges the gun. Hair-triggers are made single or double. With the former there is only one trigger to the gun, which can be used either with or without the hair. To set it, we press it forward until it locks into a catch. With the latter there are two triggers, the foremost of which is the common trigger, while the other, nearest the hand, sets the hair. The advantage of the double construction is, that we can put the gun to the shoulder and direct the line of fire *before setting the hair-trigger*. The double trigger is most used on the Continent. In Britain the single is most in vogue.

Gun-Stocks.—Gun-stocks are made almost exclusively of the wood of the walnut tree, which appears to combine in a higher degree than any other wood the qualities of soundness, strength, durability, and beauty of appearance, without excessive weight, hardness, or brittleness. Other woods have been tried to a considerable extent, but the walnut holds its ground without a rival. Birds'-eye maple, rosewood, the root of ash, &c., may be occasionally used according to the fancy of a purchaser, but no wood except the walnut enters as a general material into the manufacture of gun-stocks. The English wood is considered preferable to the French or German, being closer in the grain, finer in the texture, and generally of a more handsome figure. Before Joseph Manton improved the manufacture of fowling-pieces, the stocks were made too short; and after he had designed a new pattern of sterling excellence, other makers fell into the extreme of length, and made the stocks absurdly long. The rule is for each purchaser to suit himself, without being overstretched by a long stock, or obliged to bend the head inconveniently to a short one. In Britain stocks are made plain; on the Continent they are frequently ornamented by elaborate carving sometimes of great excellence. The stocks of Lebeda of Prague are models of elegance; and as this system of ornamenting fire-arms was a national peculiarity, it is perhaps to be regretted that the French and Belgians are departing from their own style and merely imitating the English patterns. In the Great Exhibition there was a brace of pistols stocked in ivory, the carving of which alone would probably cost from L.50 to L.100. The Americans stock their rifles differently from the British. They use much less wood, thin off the butt, and do not now carry the stock forward under the barrel. The heel or end of the butt is also hollowed out to fit the arm, as the American rifle-shooters fire from the upper part of the arm, and not from the shoulder as is customary in Britain. A pistol-hand is a handsome, and perhaps useful addition to the gun-stock. A very experienced gun-maker informed the writer of this article that he had never seen a broken stock that had a pistol-hand. Musket stocks have not hitherto been made by machinery in Great Britain or on the continent of Europe, except in Belgium, where the experiment failed. In America they are made in the following manner:—A stock is taken in the roughly-sawn state, and placed in a machine, in which it revolves. This first machine cuts out the portions on which the banding is placed. The stock is then taken to another machine, which, by a revolving drill, cuts the groove for the barrel down to the breech, and at the breech a cutter squares the groove at a right angle. Another machine turns the hold of the stock; another drills out the portion where the lock is fitted; another cuts the placing for the trigger-guard plate. Other machines cut the placings for the rest of the furniture, and the stock is so far finished as only to require a slight rasping to complete it. The parts are thus so perfect that a lock taken out of a heap will fit any stock with sufficient accuracy for military purposes. Altogether, sixteen different machines are required for forming the stock, and the operation occupies about half-an-hour.

Gun-Furniture.—The portions of a gun other than the barrel, the lock, and the stock, are termed gun-furniture. They consist of the heel-plate, which covers the butt; the break-off, into which the breeching hooks; the trigger-plate; the trigger-guard; the hammers; the escutcheons and bolt which fasten the barrel into the stock; the cap or tip of the stock; the tops, worms, and caps of the ramrod; and the screws necessary to put the gun together. Iron furniture of the best quality is made under the hammer, but a large proportion of the inferior furniture is stamped, not forged. The stamped or *pressed* articles are used for cheap guns, but they never possess the strength and solidity of the forged work. In the manufacture of gun-furniture—a scroll-guard for instance—the forgers exhibit marvellous dexterity, and turn out the article so accurately shaped that it requires little more than to be cleaned up with the file.

Pistols.—Pistols, although not generally manufactured by the same parties, are made in much the same manner as guns, with this exception, that where they are made in pairs the two barrels are forged and bored in one piece, and afterwards cut through the middle. This method saves labour, and insures that the calibres of the two barrels shall be exactly similar.

The Gun Trade.—The manufacture of guns may be divided into two great branches. The wholesale trade, which includes military arms and the commoner classes of export arms, and the retail trade, which includes the fowling-pieces and rifles of an expensive character used by sportsmen. The wholesale trade is carried on almost exclusively at Birmingham, which is now the only place in Great Britain where gun-barrels are forged. Formerly fine barrels were made in London; but the metropolitan forgers found that they could not compete with the local advantages of Birmingham, and the manufacture of barrels has centred exclusively in the latter town. Gun-furniture is also made at Birmingham; and gun-locks, especially those of the best quality, are made at Wolverhampton, where the lock-filers have acquired a high reputation for the excellence of their productions. For military muskets it has hitherto been customary for the government to contract with the Birmingham makers; but a large establishment is now in progress at Enfield, where muskets are to be made by machinery, on the plan adopted by the American government, and introduced into this country by Colonel Colt, who manufactures his revolvers by machines not previously used in Britain, and which bid fair to revolutionize the wholesale manufacture of arms. Inferior guns are finished at Birmingham, and sent out for sale. They are retailed by ironmongers and other traders, who are not gun-makers, and have no knowledge of the quality of the wares further than the price they pay, and the character of the wholesale merchant from whom they purchase. Many of these guns are of fair sound quality, and may be used for boating and rough work, but many also are blemished, being made up from articles that have been cast on account of what are termed *faults*. A barrel, for instance, that has a crack in it will be mended by hammering in a small piece of wire, and neither the salesman nor the purchaser is able to detect the artifice. The fine or *best-gun* trade, which is carried on at London, Birmingham, Edinburgh, Dublin, and the provincial towns, is of an entirely different character from what is termed the sale-shop trade. The master gun-maker is here an artist, and not merely a salesman. He receives his barrels from Birmingham, his locks from Wolverhampton, and the furniture he partly purchases from the forgers, partly makes at home. His business is to *screw the gun together;* but this technical term includes everything of importance, except the production of the raw material on which he works. He purchases the very best materials, as the price of these does not constitute nearly so large an item as the after-work to be expended on them. He subjects them to the closest inspection; and in proceeding to make up the gun he discovers the quality of every individual part. His position in the gun-trade is much the same as that of the British watchmaker who receives his materials from Clerkenwell, or of the Parisian watchmaker, who receives his from Geneva. The making of the watch is a different art from the making of the plates, wheels, and cases. And so with gun-making. The gun-maker is the artist who superintends the production of the finished work.

This branch of the gun manufacture has rapidly increased within the last few years. A London gun was formerly esteemed as superior to all others; and in the days of Joseph Manton, Henry Nock, Durs Egg, &c., it was no doubt superior to any piece that was made elsewhere in Britain. But the making of fine guns has extended to almost every part of the kingdom, and Birmingham now produces sporting guns of the very best quality, while Edinburgh has become celebrated for the accuracy of its rifles, and for the extreme finish of its higher class of fire-arms. An Edinburgh gun is now in every respect equal to the best guns of the metropolis.

When guns are stocked and screwed together, their barrels are browned to prevent them rusting. There are several methods of browning, and each maker has little modifications of his own. The following is the recipe for the wash with which barrels are stained:—

1 oz. muriate tincture of steel,
1 oz. spirits of wine,
¼ oz. muriate of mercury,
¼ oz. strong nitric acid,
⅛ oz. blue-stone,
1 quart of water.

These are well mixed and allowed to stand a month to amalgamate. The oil or grease is carefully removed from the barrels by lime, and the mixture is laid on lightly with a rag or sponge every two hours, and scratched off with a steel scratch brush every morning until the barrels are dark enough. The acid is then quenched by pouring boiling water on the barrels. Inferior barrels are stained by a different process. Muriate of mercury is dissolved in a wine-glassful of spirits of wine, and this solution is mixed with a pint of water. Some of the mixture is then poured on a small quantity of whitening, and laid on the barrel with a sponge; as soon as dry it is brushed off, and a fresh coat laid on. This is continued till the colour is dark enough, which is generally in about two days. Hot water is then applied, and the barrels are suddenly immersed in cold water to heighten the colour. Another method, called smoke-brown—although the colour produced was a greyish black—was also employed, and is strongly recommended in Mr Greener's *Treatise on the Gun;* but it is apt to injure the barrels unless performed with the utmost dexterity and care. It has therefore fallen out of use, except for a few rifle barrels. The plan is to anoint the barrels with a little vitriolic acid, which is then washed off, and the iron rubbed dry. They are then passed through the flame of the forge-fire until covered with a sooty covering, then allowed to stand in a damp cellar till rust is produced—after which they are scratched with the wire brush. The process is repeated until the colour becomes permanent. This stain looks well and stands well, but is not suited for general use.

In finishing a gun, the hammers, break-off, lock-plate, and breeches are case-hardened by the ordinary mode of case-hardening iron. The heel-plate and trigger-guard are blued, and the screws, which ought always to be of steel, are tempered. The stock is stained and oiled—or varnished and polished in the same manner as a coach pannel. The latter mode best resists rain and moisture, and is to be preferred where the varnish is good. Few of the ornamental arts of this country have made more progress than that of gun-engraving. Where formerly there were merely a few scrolls and some rude attempts at a sporting dog or game bird, we now find the gun-furniture ornamented with elaborate work of the most tasteful design and most careful execution. As the British taste, however, rejects fanciful ornament, the engraving is almost exclusively in lines cut with the graver, whereas the Germans employ the method called *cutting out,* the ground being cut away, and the figures left in relief. The latter mode produces remarkably handsome work.

The American Rifle.—The American rifle having attained to great celebrity from the unusual accuracy of its fire, we may describe one of the most recent construction. It is rather remarkable that in the Great Exhibition of 1851 there should have been no specimen of this weapon publicly exhibited. The barrel is made of cast steel thoroughly annealed, and is cut or planed outside into an octagonal shape. The barrel is 2 feet 8 inches long, and is fitted with a loading muzzle—its weight ten pounds. The patent breech is made of wrought iron, case-hardened, and is joined to the break-off by a hook, with the addition of a half-lap joint secured by a square-headed screw. This mode of fastening does away with the wood in front of the breech. The false or loading muzzle is put on by means of four steel pins about ⅛th inch in diameter, and ⅜th inch long, and the holes for these pins are drilled before the muzzle is cut off. When the muzzle is cut it is held in its place by a cramp, and the rifling is cut through both muzzle and barrel. A small globe of steel is fixed on the upper part of the muzzle to prevent the front sight being seen when the muzzle is on the barrel, so that there shall be no danger of firing it away. The bore of the barrel is scarcely ⅜ths of an inch, or about 90 round balls to the pound. The conical balls called pickets are 43 to the pound. The bore is then worked out with lead and emery until quite true. It is then cut with a *gaining* or *graduated* twist, starting at the breech with one turn in 6 feet, and ending at the muzzle with one turn in 3 feet 6 inches. There are six cuts or creases, and the sides of the lands are cut square to their surface. It is then *freed* from the breech to within 1½ inches of the muzzle, so as to reduce the friction. The lock has back-action, and a single hair-trigger. The stock is of black walnut, straight from butt to break-off, and there forms a considerable angle with the barrel. A globe-sight is fixed into the stock just behind the break-off, and a bead-sight at the muzzle. The price of such a weapon in America is from 50 to 200 dollars. With such a weapon, and a telescope sight, Capt. W. Tisdale of Utica made ten consecutive shots at 220 yards, and each shot on the average measured *less than one inch* from the centre of the bull's-eye—the whole string being 9⅝ inches. The whole of the ten shots would have gone into a small-sized playing-card. A feat of this kind is probably unparalleled in Great Britain, and it may draw the attention of our own makers to the propriety of diminishing the calibre, and increasing the speed of the ball. The loading-muzzle used by the Americans is intended to prevent the wearing of the true muzzle; but the superiority of American rifle-shooting is rather to be attributed to the smallness of the ball, and the great velocity with which it travels. The greater the velocity the straighter is the flight—that is, the course of flight has less elevation and depression than when a heavier ball is used.

In the British service the old smooth bored musket is rapidly giving way to the *new Enfield rifled musket,* a weapon of tremendous power and range. This is the arm commonly spoken of as the Minié rifle, but it is no longer a Minié. Minié's principle was to introduce an iron cup into the butt of an elongated ball on the supposition that the cup being driven into the lead by the force of the powder, would expand it and make it fit the rifle-grooves, thereby procuring the advantage of loading without hammering or forcing the ball into the muzzle. The principle was excellent, and has wrought a revolution in the small arm department of the service, but the mode of carrying it out by means of the iron cup was defective. The cup was frequently driven not *into* but *through* the ball, leaving the lead in the barrel. It was then found that the iron was superfluous, and that if the lead was hollowed out or cupped, it would expand quite sufficiently. Such is the ball now in use for the military rifle, and Mr Pritchett received an award of L.1000 from government for its production.

The cost of these muskets as made by contract, has been L.3, 9s. 0¼d. As made at Enfield the cost has been L.3, 4s. 7½d.; but if made by machinery, and an order given for 1,000,000, Col. Colt offered to supply them at 30s. In the opinion that this price was not too low, Col. Colt was borne out by Mr Anderson, chief engineer in the royal arsenal at Woolwich, and by the celebrated engineer Mr Nasmyth. The contract price of the musket in the United States is from 10 to 12 dollars—from L.2 to L.2, 10s. The price at which the Belgian rifled musket is made in the government factory is 42 francs, and a musket of the same pattern could be made in this country at 36s. or 37s.

That the rifled musket used in the British service is one of the most powerful weapons ever invented in the department of small arms, is unquestionable, but it requires improvement. As made at present it has several drawbacks. After being fired even a small number of shots, it is so difficult to load that the men using it have complained that they could not send the charge home. From the method of stocking also it has been found impossible to draw the ramrod in wet weather. The pull on the trigger is considerably too great for accurate shooting, and the method of forging the sight-supports on the barrel instead of using a slide-sight prevents the guns from being correctly regulated. These are serious disadvantages, and they require the renewed attention of the military authorities. It is well known that a good sporting rifle can be fired 100 or 150 times without cleaning. It is therefore a reproach to the military weapon that 20 or 25 shots have been found to disable it. The guns, however, are of admirable workmanship, and only require some slight improvements to render them the best small arms in any service.

The following is the account of the sum voted by the House of Commons for the supply and repair of small arms in each year from 1842–43 to 1854–55, and of the sum actually expended.

Year.	Amount voted.	Amount expended.		
1842–3	L.180,000	L.114,660	15	6
1843–4	136,000	118,936	19	7
1844–5	90,000	111,336	11	9
1845–6	84,379	117,317	13	8
1846–7	120,000	135,377	7	6
1847–8	120,000	134,769	2	10
1848–9	140,000	139,365	8	0
1849–50	120,000	122,885	15	0
1850–1	90,000	88,979	12	4
1851–2	76,000	37,664	0	8
1852–3	78,000	61,639	18	10
1853–4	135,800	*26,931	4	0
1854–5	161,400			

* This account is incomplete.

The following table shows the total supply of arms *made in London* for the Government and East India Company from 1841 to 1850 Since the latter date the government contracts have been almost entirely withdrawn from the metropolis, on account of a trifling difference in price; and the excellent body of workmen formerly assembled in London have betaken themselves to other trades or to other localities:—

Dates.	E. India Company.	Government.	Total.
1841	20,150	7,660	27,810
1842	36,353	12,926	49,279
1843	34,880	12,270	47,150
1844	25,362	13,496	38,858
1845	49,623	12,539	62,162
1846	50,880	16,336	67,216
1847	57,214	18,378	75,592
1848	55,068	23,862	78,930
1849	71,381	26,366	97,747
1850	26,025	13,607	39,632

Total of ten years, 584,376, or an average of 58,437 for each year.

Revolvers.—Among the arms recently introduced into this country and manufactured to a large extent is the revolver or repeating pistol. The principle is not new, as revolvers of a construction nearly similar to those now in use are to be found in the museums of old arms. To Col. Samuel Colt of the United States belongs the merit of reviving this species of weapon; and he has a patent, dated 1836, for his pistol, which is universally known as Colt's revolver. Messrs Deane, Adams, & Deane of London have also a patent for another form, which differs from Colt's in several essential particulars. Revolvers have long been made in this country, but they were made of a large mass of metal bored into the required number of barrels, the whole of the barrels being of the same length. This weapon was so clumsy as to be almost useless. The new revolver is made with one single barrel of the full length, and a revolving chamber only long enough to contain the charge, and bored into five or six compartments. This chamber is made of cast steel, and is so fitted that it can be removed by drawing a bolt. This gives the advantage of enabling a spare chamber to be used, which can be kept ready loaded, and the number of shots is thus doubled. With a 5-shot pistol and two chambers 10 shots can be fired without re-loading. In introducing the revolver in America, Col. Colt expended a very large amount of money without reaping a return until 1849-50, when the disturbed state of Florida and Texas, and afterwards the Mexican war, established the reputation of his arms. In his evidence before a select committee of the House of Commons in 1854, he mentioned the curious fact that, while he was supplying the American government with pistols at 25 dollars each, the soldiers were selling them to traders at 75 to 150 dollars, and sometimes as high as 200 dollars each. He has now a manufactory at Hartford, in America, where, in 1853, he turned out about 50,000 revolvers; and another manufactory at Vauxhall, London, where he employs between 200 and 300 workmen, and where he could produce nearly 1000 pistols per week, made almost entirely by machinery. The difference between a Colt and a Deane & Adams pistol is, that the Colt has a lever ramrod under the barrel, which is part of his patent, and that the hammer requires to be drawn up every time the pistol is fired. The Deane & Adams, on the contrary, has a lever at the side, and can be fired by merely drawing the trigger. A recent improvement of Mr Adams has produced a pistol that will fire either by drawing up the hammer or by pulling the trigger, and this pistol is considered the most perfect that has hitherto appeared. Another form, and one of great merit, has a spur under the trigger-guard, and the arm can only be fired when the spur is pulled by the middle finger, while the trigger is pulled by the fore finger. Between the merits of these weapons it is difficult to institute an impartial comparison. It may, however, be laid down as a general maxim, that every pistol that will fire by merely drawing the trigger is a dangerous weapon. The trigger may be drawn by accident, as in the case of the late lamented Dr Hector Gavin, who was shot by one of these weapons, to the regret of the service and the nation. It may perhaps be said, however, that Colt's pistol is more safe in its construction—Deane and Adams's more effective in competent hands. But all the revolvers require to be handled with caution.

Another objection to any arm that fires merely by the draw of the trigger is, that if the main-spring be strong enough to explode the percussion cap with certainty, it becomes too strong for the finger, and the shooter swerves from his aim. If, on the contrary, it is so weak as to pull easily, there is no certainty that the cap will explode except under the most favourable circumstances. In very dry weather, and with good caps, it may explode every time it is struck by the hammer; but in damp weather, or with inferior caps, the arm misses fire, and the shooter is disappointed, or it may even be that his life is endangered. There is thus a compensation of advantages in each weapon, and a selection must be made according to the purpose for which the arm is intended. Repeating rifles, on the same principle as the pistols, are manufactured and used in the United States, but they have not yet been adopted in Britain.

(P. E. D.)

GUNNERY

Is the art, in a restricted sense, of determining the motions or ranges of projectiles discharged from cannon, mortars, howitzers, and other kinds of artillery; and, in a more general sense, of determining not only the motions of such bodies, but also the arrangements by which they are rendered effective instruments of war.

I.—THEORY OF GUNNERY.

The use of fire-arms had been long known before any theory concerning them was attempted. Nor is this remarkable, as the theory of the motion of projectiles depends on a knowledge of certain laws of nature which were not discovered till many years afterwards. It was different as regards the improvement of those defensive arrangements which had been found sufficient in the earlier times to afford protection against the more ancient engines of war, or, on the other hand, to cover those who were called upon to use them. The architects of the middle ages (see FORTIFICATION) quickly saw the necessity of modifying the forms and proportions of the ancient walls which then surrounded fortified towns, and rendering them more suitable both for the use and for the resistance of the newly-discovered artillery adapted for the use of gunpowder. The Cavaliere Saluzzo of Turin has indeed shown, from the archives of his native town, that Giorgio Martini, Architetto Senese, undertook the task of remodelling the ancient walls of castles and of towns even before the commencement of the sixteenth century, as Martini died in 1506. In his plans the profiles of the old castle are not much altered; but the trace is greatly modified, so as to produce a more perfect reciprocal or flanking defence, either by a combination approximating to something like the bastioned trace, or by *capannati*—so called from their resemblance to a woodman's hut—in the ditch, a work in principle the same as the caponnieres subsequently invented by Dürer. Nothing, perhaps, is more calculated to exhibit the military spirit which pervaded the Italian architects, sculptors, and others, as well as those of the military profession, than the list of Italian authors on the art of war, in the corps papers of the Royal Engineers, which was drawn up by an accomplished lady, Mrs Lennox Conyngham, from an inspection of the libraries of Rome alone. In that list appears the name of Nicholas Tartaglia, who was the first author who wrote professedly on the flight of cannon-shot. In 1537 he published a book at Venice, entitled *Nova Scientia;* and afterwards another, printed at the same place in 1546, in which he treats of these motions. His discoveries were but few, on account of the imperfect state of mechanical knowledge at that time. He determined, however, that the greatest range of cannon was with an elevation of forty-five degrees; and he likewise ascertained, contrary to the opinion of practitioners, that no part of the track described by a bullet is a right line, although the curvature is in some cases so small that it is not attended to. He compared it to the surface of the sea, which, though it appears to be a plane, is yet undoubtedly incurvated round the centre of the earth. He also assumes to himself the invention of the gunner's quadrant, and often makes shrewd guesses as to the results of untried methods. But as he had not opportunities of observing practice, and founded his opinions solely on speculation, he was condemned by most of the succeeding writers, though often without any sufficient reason. The philosophers of those times also intermeddled in the questions which hence arose; and many disputes on motion occurred, especially in Italy, where they continued till the time of Galileo, and probably gave rise to his celebrated *Dialogues on Motion.* These were published in the year 1638; but in the interval, and before Galileo's doctrine was thoroughly established, many theories of the motion of military projectiles, and many tables of their comparative ranges, at different elevations, were published; all of them egregiously fallacious, and utterly irreconcileable with the motions of these bodies. Many of the ancients, indeed, indulged in speculations concerning the difference between natural, violent, and mixed motions; but when they did so, scarcely two of them could agree in their theories.

It is strange, however, that during all these contests so few of those who were intrusted with the charge of artillery thought it worth while to bring these theories to the test of experiment. Mr Robins informs us, in the preface to his *New Principles of Gunnery*, that he had met with no more than four authors who had treated on this subject. The first of these is Collado, who has given the ranges of a falconet carrying a three-pound shot to each point of the gunner's quadrant. But, from his numbers, it is manifest that the piece was not charged with its customary allotment of gunpowder. The results of his trials were, that the point-blank shot, or that in which the path of the ball did not sensibly deviate from a right line, extended 268 paces. At an elevation of one point (or $7\frac{1}{2}$° of the gunner's quadrant), the range was 594 paces; at an elevation of two points, 794 paces; at three points, 954 paces; at four, 1010; at five, 1040; and at six, 1053 paces. At the seventh point, the range fell between those of the third and fourth; at the eighth point, it fell between the ranges of the second and third; at the ninth point, it fell between the ranges of the first and second; at the tenth point, it fell between the point-blank distance and that of the first point; and at the eleventh point, it fell very near the piece. The paces spoken of by this author are common steps.

The year after Collado's treatise, another appeared on the same subject, by one Bourne, an Englishman. His elevations were not regulated by the points of the gunner's quadrant, but by degrees; and he ascertained the proportions between the ranges at different elevations and the extent of point-blank shot. According to him, if the extent of the point-blank shot be represented by 1, the range at 5° elevation will be $2\frac{2}{9}$, at 10° it will be $3\frac{1}{3}$, at 15° it will be $4\frac{1}{3}$, at 20° it will be $4\frac{5}{6}$, and the greatest random will be $5\frac{1}{2}$. This last, he tells us, happens in a calm day, when the piece is elevated to 42°; but according to the strength of the wind, and as it favours or opposes the flight of the shot, it may be from 45° to 36°. He has not informed us with what piece he made his trials, though from his proportions it seems to have been a small one. This, however, ought to have been attended to, as the relation between the extent of different ranges varies extremely according to the velocity and density of the bullet.

After him, Eldred and Anderson, both Englishmen, published treatises on this subject. The first published his treatise in 1646, and gave the actual ranges of different pieces of artillery at small elevations, all under ten degrees. His principles were not rigorously true, though not liable to very considerable errors; yet, in consequence of their deviation from the truth, he found it impossible to make some of his experiments agree with his principles.

Before proceeding further with the history of gunnery, or passing the epoch at which the writings of Galileo had prepared the way for a sounder knowledge of its principles it is only an act of justice to Nicholas Tartaglia to record what he *actually* either knew or conjectured on the subject. The second of his works, published, as before stated, in 1546, was translated into English by Mr Cyprian Lucar, and published in London in 1588. It consists of three books of *Colloquies concerning the Arte of Shooting;* and the motive for writing it is thus stated by Tartaglia in his dedication of the book to King Henry VIII., in the language of Lucar's translation :—"It was never my profession, not at any time have I delighted to shoot in any harchibuse, hande-gunne, or in any other small or great piece of artillerie, nor doe intende to shoote hereafter in any of them; but one only question which a skilfull gunner in 1531 did aske of me in Verona provoked mee at that tyme to thinke thereupon, and by that occasion to finde out the order and proportion of shootes or markes neare hand, and also at markes far off, according to the variable clevation of the piece which doth shoote, whereof I should never have had any care, if that gunner had not with his saide question stirred me up to deale in the same." The idea having been thus raised in his mind, Tartaglia was stimulated by the threatened war with the Turks to publish, in 1537, a short *Treatise of Shooting in Gunnes, to the ende* (as he observes) *that my devises in the same might bee considered of.* This book, he says, did no good; and as he continued to be asked many questions by men of station and learning, as well as by gunners, on the subject, he determined to answer all such queries in his second book, which is therefore arranged in the form of dialogues between Tartaglia and the Duke of Urbino, the Prior of Barletta, the Lord of Achaia, bombardiers, gunners, and gun-founders.

1. In the third Colloquie of the 1st Book he lays down as a proposition, that "a pellet doth never range in a right line except it be shot out of a piece right up towards heaven, or right downe towards the centre of the world."

In proving this proposition, Tartaglia assumes that the effective weight of the pellet, or ball, is diminished in proportion as the velocity is increased, and *vice versa;* and hence that the ball is less drawn to the earth at the first part of its flight than it is at the last. The explanation of the fact is therefore founded upon erroneous principles, but the reasoning from it is good; for Tartaglia says :—

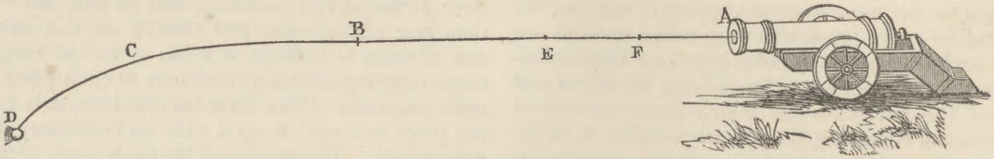

Fig. 1.

"If now it be supposed that in any portion AB of the trajectory of the ball, the ball moves in a right line, divide AB in two equal parts at E; now, as the velocity is greater in AE than it is in EB, the ball will be less urged to the ground in the first than it is in the second half, and hence that the line EB cannot be as nearly straight as AE; or, subdividing again AE into two parts at F, FE will be more removed from a straight line than AF; and so on—proving that no part of the trajectory could be absolutely straight." Considering the imperfect knowledge of the time, this demonstration was perhaps as much as could be expected, as it distinctly recognises the principle, that weight or gravity continued to draw the ball to the earth from the first to the last moment of its motion under the impulse of the propelling force, and hence that it could not at any moment move in a straight line.

2. *Point-blank.*—Tartaglia, in removing the scruples of his imaginary auditors, explains in the most satisfactory manner the different acceptations of this term, as now applied in the British and French service.

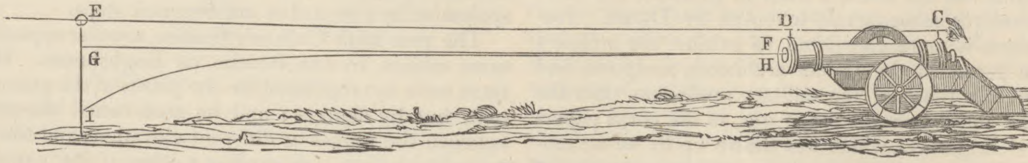

Fig. 2.

In this cut it is assumed that CD is, by a proper arrangement of sights at the breech and muzzle, made parallel to the axis of the gun; and hence, that the line of aim, CDE, is parallel to FG, or to the axis of the gun produced; in which case it is manifest that the ball could not arrive at G, but would come to the ground at I, which point, provided GI be equal to the height of the axis of the gun above the ground, marks the point-blank range of the British artillerist, or the lateral space passed over by the ball in the time it takes to fall to the ground. For convenience sake, the axis is supposed to be horizontal, and the range is also taken on a horizontal plane.

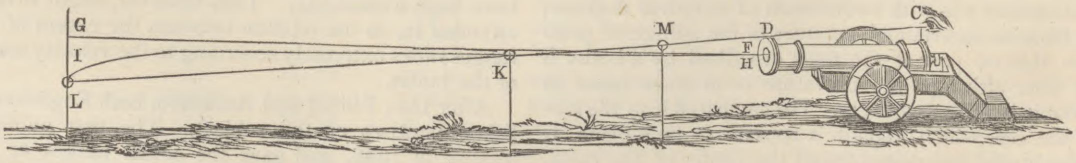

Fig. 3.

If the sights are so arranged that one shall be higher from the axis of the piece than the other, the line of sight or aim will no longer be parallel to the axis, but, when prolonged, will make an angle with, or intersect it. If the muzzle sight be the higher, always estimating from the axis, the intersection will take place behind the breech, and the line of the axis will be depressed below that of sight; if, on the contrary, the breech sight be the higher, the intersection will take place in front of the muzzle, and the line of the axis will be elevated above that of sight. The latter is the case when the line of natural aim, or sight, is used, or that passing through the highest point of the breech-ring and the low sight, or highest point, of the muzzle-ring. The case is analogous to that of fig. 3, where FG represents the line of the axis produced, CDL the visual line, and HI the true line of flight or trajectory. Now, it is evident from this drawing that the shot intersects the line of vision just at K, and hence that if the mark M chanced to be nearer the gun, though on the visual line, it would not be struck, at least in the centre, by the ball, which, in this part of its course, would be below that line. After passing K, the line of flight rises above the visual line, but in its descent, meets it again when I and L coincide, and if the mark M is placed at that point the ball will strike it.

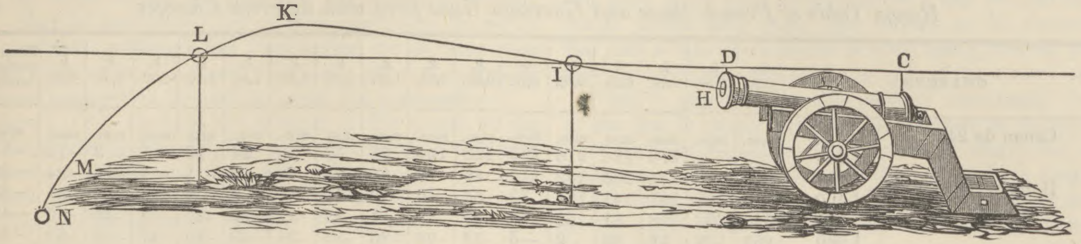

Fig 4.

This is better shown in fig. 4, where the visual line CDL is represented horizontal—the axis, therefore, being elevated by the angle made by the intersection of the axis prolonged and the visual line. In this case, then, the ball rises and intersects the visual line at I, and again on its descent at L, proceeding on to N, so that the mark M would be struck if placed anywhere on the trajectory from L to N; and when the line CD is tangent at once to the muzzle and breech of the gun, or passes through any fixed and invariable marks or sights placed for the purpose on the summit of the base and muzzle rings, it becomes the natural line of aim or sight; and if placed horizontal, as in the figure, determines the point-blank range, or the distance from the gun of the second intersection L of the trajectory with the natural line of sight.

Didion.

In the excellent treatise on artillery by Didion, *chef d'escadron* of the French artillery, the meaning of the term *but-en-blanc*, or point-blank, and the range corresponding to it, are stated as above, and, as observed by Didion, the point K of fig. 3, or I of fig. 4, being, from the ordinary construction of guns, so near to the muzzle (in a 68-pounder about seven feet), may be considered as corresponding with the actual point of intersection of the axis of the gun with the line of sight, the point of second intersection only being therefore of practical importance as determining the range.

It is very necessary to keep in view the two different interpretations of point-blank and point-blank range which have been here explained, in comparing the published ranges of English, as well as American and foreign guns, as will be perceived from the following statement:—

Griffiths (*Artillerist's Manual*, 6th edition, 1854) gives—"The point-blank range of iron 32, 24, 18, and 12-pounders, with solid shot, as varying from 380 to 260 yards; from which to 1200 yards every ¼ degree increases the range 100; and from 1200 to 1500 every ¼ degree increases the range about 50 yards; and the point-blank range of brass medium 12, 9, and heavy 6-pounders, with solid shot, at 300 yards, and from which to 700 yards, every ¼ degree elevation increases the range 100 yards; from 700 to 1000 every ¼ degree increases it 75 yards, and from 1000 to 1500, each ¼ degree increases it 50 yards.

Captain Mordecai, in the *Ordnance Manual of the United States Army*, 1850, gives the following ranges:—

	Charge.	Degrees Elevation.	Yards.
6-pounder field-gun.	1·25 lbs.	0	318
		1	674
		2	867
		3	1138
		4	1256
		5	1523
12-pounder. field-gun.	2·5 lbs.	0	347
		1	662
		1 30′	785
		2	909
		3	1269
		4	1455
		5	1663
24-pounder siege and garrison, on siege carriage.	6 lbs.	0	412
		1	842
		1 30′	953
		2	1147
		3	1417
		4	1666
		5	1901
	8 lbs.	1	883
		2	1170
		3	1454
		4	1639
		5	1834

It may be observed, that both in the American and English service the word "dispart" is used, and means the natural tangent to the angle of natural sight or aim, the length of the gun measured from the rear of the base ring to a line raised vertically at the highest point of the swell of the muzzle, or at the permanent mark or sight fixed there, being the radius; and hence the angle of dispart is synonymous with the angle of natural sight, an angle which in English iron ordnance varies in construction from 1° to 2° 30′, and in the French service varies also, as shown in the annexed table, extracted from *Piobert*.

Table of the Angles of Natural Aim or Sight of French Guns.

Now, Griffiths states the point-blank range of the 12-pounder iron, with 4 lbs. of powder, as 360 yards; and in the following table, it will be observed that the point-blank range of the French 12-pounder, a gun which would be equivalent to a 14-pounder English, is given as 650 metres, equal to 710 yards. In like manner Captain Mordecai gives the point-blank range of the 12-pounder American field-gun, with 2 lbs. 5 oz., as 347 yards; whereas the French 12-pounder with a similar charge (see following table) gives 540 metres, or 600 yards nearly. The French point-blank range in the first case corresponds to an elevation of 1° of English practice, and in the second to an elevation of less than 1°, as Captain Mordecai gives the range of 1° as 662 yards, though the angle of dispart of the French siege 12-pounder is 1° 9′ 4″, that of the 12-pounder field-gun being 0° 59′ 39″.

This Table is for guns in perfect condition; when much used the *hausses* must be augmented. The Hausse-de-Mire corresponds to the tangent scale of British ordnance, the degrees being replaced by the natural tangents of the required elevations in millimetres.

Cyprian Lucar—"Dispart."

The term dispart is of ancient use, and Lucar (1588) lays down as one of his maxims, that "every gunner, before he shootes, must trulie disparte his peece, or *give allowance for the disparte;* and when he dispartes a peece, he ought to set the said dispart in the midst and uppermost part of mettall over the mouth of the peece;" a caution equally necessary at the present day, as every gunner ought to make himself acquainted with the dispart of his gun, and with the range corresponding to it, and then familiarize his eye with that distance, which would thus become a base of comparison for ranges within and without.

3. *Mode of action of gunpowder. Resistance of the air.*—As the real nature of the products of combustion, as well as of combustion itself, is a comparatively recent discovery, the exact theory of its action was not to be expected from Tartaglia, and yet he gives a very reasonable account of it. In the 22d Colloquie, in which a gunfounder inquires why guns generally burst at the breech, Tartaglia answers to this effect, that the *great exhalation proceeding from the saltpetre* acts against the ball, and as it is difficult to put it at first in motion, though easy to keep up the motion when once given, should the gun be too weak in that part it will yield to the force of the windie *exhalation* and burst; but if the metal be sufficiently strong, and the ball be moved, there will be no fear of bursting, unless by any accidental cause the motion of the ball be arrested, when the gun may burst, as it sometimes does, near the muzzle; "for, so soone as the pellet is in moving, that exhalation will continue with ease if no other let do happen, but so soone as the pellet commeth to the mouth of the peece, it finds all the aire without the peece, and by how much the pellet, together with the said exhalation that thrusteth it to assault the aire, commeth more swiftly, by so much the more united and with a *greater force,* doth the aire oppose itselfe very strongly to resist that sudden moving, and thereupon, in that place, another difficultie or strife riseth betweene the exhalations within (which thrusteth forth the pellet), and the aire without,—that is to say, the exhalation would goe out of the concavitie, and the aire without doth resist the same; but in the end, the exhalation within being of a greater force, and getting the victorie, breaketh forth and teareth in pieces his said enemie. And then the mouth of the peece being, as it were, in the middest of the strife, doth alwaies suffer very much; and this is the cause that the peece, lacking his due thicknesse on the said place, or for some other unknowne fault, doth there easily breake."

4. *The length of the gun should be duly proportioned to the charge.*—It had been supposed that the longer the gun the greater would be its range, but Tartaglia in the 11th, 12th, and 13th Colloquies, points out that though the long culvering of these days had a greater range than the shorter cannon, it required a correspondingly greater charge—that of the culvering being $\frac{4}{5}$ths of the weight of the shot, and that of the cannon only $\frac{2}{3}$ds; and further reasons, that for any given charge there is one length only which can give the maximum range, as if too short, part of the powder will be expelled before ignition, and so much power be lost; and if too long, the ball would be in the gun after the total ignition of the powder, and be checked in its progress by friction against the bore—the proper limit of length being that which will place the ball exactly at the mouth at the moment when all the powder shall be on fire, and the windie exhalation be at its maximum, "for on that instant all the expulsive vertue of the powder begins to worke on the pellet in the chiefe of his furie or force, and after that vertue expulsive hath wrought on the pellet, the said pellet, finding nothing to let or resist his range (*except the aire*), will flie more farther than if the concavitie of the peece had beene more longer or more shorter." Notwithstanding the partial imperfection of the reasoning, this was a curious approximation to the truth, as regards the exact proportion of the charge "for giving the maximum velocity" to the length

of the gun; and though Tartaglia did not treat of the more general question of the inexpediency of increasing both charge and length beyond a certain point, he gave the explanation of the fact when he stated that the air resists the more, the more violent the action of the expulsive exhalation. Had he known the law of that resistance, he would have probably perfected the explanation by showing that ultimately the resistance would become so great as to require enormous strength in the gun to resist the concussion.

Robins (1742) explains the relation of the length of the bore to the charge and velocity communicated to the ball, by construction thus:—"Let AB represent the axis of the piece; draw AC perpendicular to it, and to the asymptotes AB and AC describe any hyperbola LEF, and draw BF parallel to AC; find out now the point D where the rectangle ADEG is equal to the hyperbolic area DEFB, then will AD represent that height of the charge which communicates the greatest velocity to the shot; whence AD being to AB as 1 to 2·71828, as appears by the table of logarithms, from the height of the line AD thus determined, and the diameter of the bore, the quantity of powder contained in the charge is easily known.

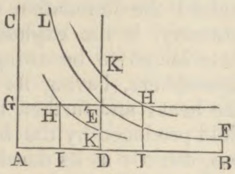

Fig. 5.

"If, instead of this charge, any other fitting the cylinder to the height AI be used, draw IH parallel to AC, and through the point H, to the same asymptotes AC and AB, describe the hyperbola HK; then the greatest velocity will be to the velocity communicated by this charge AI in the subduplicate proportion of the rectangle AE to the same rectangle diminished by the trilinear space HKE." This explanation depends upon the proposition relative to the determination of the velocity of the ball with a given charge to be subsequently referred to, but Robins' reasoning is here anticipated in order to place the result in opposition to that of Tartaglia.

Hutton (1812). In his tracts published in this year, Hutton details the experiments in gunnery carried on by himself and Major Blomfield, Royal Artillery (afterwards General Lord Blomfield), and other able artillery officers, for several years in the Warren, now arsenal of Woolwich. Some of these had been previously published in 1786 in a quarto volume of tracts, and a previous set, made in 1775, in the *Philosophical Transactions* for 1778—Dr Hutton having been awarded the annual gold medal of the Royal Society for his paper containing the results of the experiments, and the deductions drawn from them.

Some of these experiments were directed to the determination of the relation between the charge of powder, the length of the bore, and the resulting velocity. The experiments were made with five guns of the same calibre, being intended to discharge a ball of 16 oz. weight, but of lengths varying from 30·3 inches to 82·3; the lengths of the bores varying from 28·53 to 80·80 inches, gun No. 5 being intended to be reduced in length by cutting off successive portions after a certain number of rounds of practice, so as to test the effect, on the velocity, of a variation in the length of the bore. The deductions are thus stated by Dr Hutton:—

"1*st*. The law determined by the previous experiments between the charge and the velocity of ball is again confirmed—namely, that the velocity is directly as the square root of the weight of powder, as far as to about the charge of 8 oz. (half the weight of the ball used); and so it would continue for all charges were the guns of an indefinite length. But as the length of the charge is increased, and bears a more considerable proportion to the length of the bore, the velocity falls the more short of that proportion.

"2*d*. That the velocity of the ball increases with the charge, to a certain point, which is peculiar to each gun *where it is greatest;* and that by further increasing the charge, the velocity gradually diminishes, till the bore is quite full of powder. That this charge for the greatest velocity is greater as the gun is longer, but not greater, however, in so high a proportion as the length of the gun is; so that the part of the bore filled with powder bears a less proportion to the whole in the long guns than it does in the shorter ones; the part of the whole which is filled being, indeed, nearly in the subduplicate ratio of the length of the empty part.

"3*d*. It appears that the velocity continually increases as the gun is longer, though the increase in velocity is but very small in respect to the increase in length, the velocity being in a ratio somewhat less than that of the square roots of the length of the bore, but somewhat greater than that of the cube roots of the length, and is, indeed, nearly in the middle ratio between the two.

"4*th*. It appears from the ranges determined by these experiments that the range increases in a much less ratio than the velocity, and, indeed, is nearly as the square root of the velocity, the gun and elevation being the same. And when this is compared with the property of the velocity and length of gun in the foregoing paragraph, it appears that we gain extremely little in the range by a great increase in the gun, the charge being the same. And indeed, the range is nearly as the 5th root of the length of the bore; which is so small an increase as to amount only to about $\frac{1}{7}$th part more range for a double length of gun."

The comparison of these results of experiments made at a time of vastly advanced knowledge, with the statements of Tartaglia, must, notwithstanding some of their imperfections, justify a very high estimate of the position which he would have held amongst writers on gunnery had he lived after the discoveries of Galileo and Newton.

In 1638 Galileo printed his Dialogues on Motion. In these he pointed out the general laws observed by nature in the production, resolution, and composition of motion, and was the first who described the action and effects of gravity on falling bodies. On these principles he determined that the flight of a cannon-shot, or any other projectile, would be in the curve of a parabola, except in as far as it was diverted from that track by the resistance of the air. He has also proposed the means of examining the inequalities which thence arise, and of discovering what sensible effects that resistance would produce in the motion of a bullet at a given distance from the piece.

Though Galileo had thus shown that, independently of the resistance of the air, all projectiles would, in their flight, describe the curve of a parabola; yet those who came after him seem never to have imagined that it was necessary to consider how far the operations of gunnery were affected by that resistance. The subsequent writers indeed boldly asserted, without making the experiment, that no considerable variation could arise from the resistance of the air in the flight of shells or cannon-shot. In this persuasion they supported themselves chiefly by considering the extreme rarity of the air compared with those dense and ponderous bodies; and at last it became an almost generally established maxim, that the flight of these bodies was nearly in the curve of a parabola.

In 1674, Mr Anderson, before mentioned, published his treatise on the Nature and Effects of the Gun; in which he proceeds on the principles of Galileo, and strenuously asserts that the flight of bullets is in the curve of a parabola; undertaking to answer all objections which could be brought to the contrary. The same thing was also undertaken by Mr Blondel, in a treatise published at Paris in 1683, where, after long discussion, the author concludes that the variations from the resistance of the air are so slight as scarcely to merit notice. The same subject is treated of in the *Philosophical Transactions* (No. 216, p. 68) by Dr Halley; and he also, swayed by the great disproportion between the density of the air and that of iron or lead, thinks it reasonable to believe that the resistance of the air to large metal shot is scarcely discernible; although in small and light shot he owns that it must be accounted for.

But though this hypothesis went on smoothly in speculation, yet Anderson, who made a great number of trials, found it impossible to support it without some new modification. For, though it does not appear that he ever examined the comparative ranges of either cannon or musket shot when fired with their usual velocities, yet his experiments on the ranges of shells thrown with small velocities, in comparison of those above mentioned, convinced him that their whole track was not parabolical. But, instead of drawing the proper inference from this, and concluding that the resistance of the air was of considerable efficacy, he framed a new hypothesis, which was, that the shell or bullet, at its first discharge, flew to a certain distance in a right line, from the end of which line only it began to describe a parabola. And this right line, which he calls the line of the impulse of the fire, be supposes to be the same in all elevations. Thus, by assigning a proper length to this line of impulse, it was always in his power to reconcile any two shots made at different angles, let them differ as widely as we may please to suppose. But this he could not have done with three shots; nor, indeed, does he ever tell us the result of his experiments when three ranges were tried at one time.

When Sir Isaac Newton's *Principia* was published, he particularly considered the resistance of the air to projectiles which move with small velocities; but, as he never had an opportunity of making experiments on those which move with such prodigious swiftness as shots and shells, he did not imagine that a difference in velocity could make such differences in the resistance as are now found to take place. Sir Isaac found, that in small velocities the resistance was increased in the duplicate proportion of the swiftness with which the body moved; that is, a body moving with twice the velocity of another of equal magnitude, would meet with four times as much resistance as the first; with thrice the velocity, it would meet with nine times the resistance; and so on. This principle itself is now found to be defective with regard to military projectiles; though, if it had been properly attended to, the resistance of the air might have been reckoned much more considerable than was commonly imagined. So far, however, were those who treated this subject scientifically from giving a proper allowance for the resistance of the atmosphere, that their theories differed most egregiously from the truth. Huygens alone seems to have attended to this principle. In the year 1690 he published a treatise on Gravity, in which he gave an account of some experiments tending to prove that the track of all projectiles moving with very swift motions was widely different from that of a parabola. All the rest of the learned acquiesced in the justness of Galileo's doctrine, and erroneous calculations concerning the ranges of cannon were accordingly given. Nor was any notice taken of these errors till the year 1716. At that time Ressons, a French officer of artillery, distinguished by the number of sieges at which he had served, by his high military rank, and by his abilities in his profession, presented a memoir to the Royal Academy, importing that, "although it was agreed that theory joined with practice did constitute the perfection of every art, yet experience had taught him that theory was of very little service in the use of mortars; that the works of Blondel had justly enough described the several parabolic lines, according to the different degrees of the elevation of the piece; but that practice had convinced him there was no known theory for the effect of gunpowder; for, having endeavoured, with the greatest precision, to point a mortar agreeably to these calculations, he had never been able to establish any solid foundation upon them."

From the history of the academy, it does not appear that the sentiments of Ressons were at any time controverted, or any reason offered for the failure of the theory of projectiles when applied to use. Nothing further, indeed, was done till the time of Benjamin Robins, who, in 1742, published a work entitled *New Principles of Gunnery*, in which he has treated particularly, not only of the resistance of the atmosphere, but of almost everything else relating to the flight of military projectiles, and, indeed, advanced the theory of gunnery much nearer perfection than it had ever before attained.

The first thing considered by Mr Robins, and which is indeed the foundation of all other particulars relative to gunnery, is the explosive force of gunpowder, which he determined to be owing to an elastic fluid similar to our atmosphere, having its elastic force greatly increased by the heat; and further, that the elasticity or pressure of the fluid produced by the firing of gunpowder is, *cæteris paribus*, directly as its density.

"As different kinds of gunpowder produce different quantities of this fluid in proportion to their different degrees of goodness, before any definite determination of this kind can take place, it is necessary to ascertain the particular species of powder that is proposed to be used: hence Mr Robins determined, in all his experiments, to make use of government powder, as consisting of a certain and invariable proportion of materials, and therefore preferable to such kinds as were made according to the fancy of private persons.

"This being settled, we must further premise these two principles,—1. That the elasticity of this fluid increases by heat and diminishes by cold, in the same manner as that of the air. 2. That the density of this fluid, and, consequently, its weight, is the same with the weight of an equal bulk of air, having the same elasticity and the same temperature."

By exploding powder in a receiver connected with a mercurial gauge, Robins determined that an ounce of powder produced, on explosion, nearly 575 cubic inches of gaseous fluid possessing the same elasticity as common air; and, making allowance for the increase of elasticity due to the heat of the receiver and of the red-hot iron used for igniting the powder, that the gas, when reduced to the actual temperature, would have filled 460 cubic inches. Now, to determine the ratio of the bulk of the gunpowder to the bulk of this fluid, remembering that 17 drams avoirdupois of gunpowder fill 2 inches, the proportion $16 : 17 :: 460 : 488\frac{3}{4}$ gave the number of cubic inches of an elastic fluid equal in density with the air produced from 2 cubic inches of powder; "whence the ratio of the respective bulks of the powder and of the fluid produced from it, is nearly as 1 to 244.

"If this fluid, instead of expanding when the powder was fired, had been confined in the same space which the powder filled before the explosion, then it would have had, in that confined state, a degree of elasticity 244 times greater than that of common air; and this independent of the great augmentation which this elasticity would receive from the action of the fire at that instant.

"Hence, then, we are certain, that any quantity of powder, fired in a confined space, which it adequately fills, exerts, at the instant of its explosion, against the sides of the vessel containing it, and the bodies it impels before it, a force at least 244 times greater than the elasticity of common air, or, which is the same thing, than the pressure of the atmosphere; and this without considering the great addition which this force will receive from the violent degree of heat with which it is affected at that time."

The augmentation of the elasticity of air by temperature to the extent of "the *extremest* degree of red-hot iron, Mr Robins investigated by heating to an incipient white heat a portion of a musket barrel six inches long, closed at one end and drawn out at the other conically, to an aperture of one-eighth of an inch in diameter. The aperture was first closed by a wire, and the conical end of the tube after being heated was plunged into water, and the whole left to cool to the ordinary temperature of the air, when, the wire being removed, the water rushed in to fill the space now left vacant by the again contracted air. By the average of three experiments he determined the weight of the water which entered the barrel, and knowing the quantity or weight of water which would fill the whole, the difference between the two was the weight of water which would fill the portion of the barrel occupied by the cooled air. The proportion between the space occupied by the air before expanded by heat, and the same air when expanded by an incipient white heat, was determined by these experiments to be as 194$\frac{1}{3}$ to 796.

"As air and this fluid appear to be equally affected by heat and cold, and consequently have their elasticities equally augmented by the addition of equal degrees of heat to each; if we suppose the heat with which the flame of fired powder is endowed to be the same with that of the extreme heat of red-hot iron, then the elasticity of the generated fluid will be greater at the time of the explosion than afterwards, when it is reduced to the temperature of the ambient air, in the ratio of 796 to 194$\frac{1}{3}$ nearly. It being allowed then (which surely is very reasonable) that the flame of gunpowder is not less hot than red-hot iron, and the elasticity of the air, and consequently of the fluid generated by the explosion, being augmented in the extremity of this heat, in the ratio of 194$\frac{1}{3}$ to 796, it follows, that if 244 be augmented in this ratio, the resulting number, which is 999$\frac{1}{3}$, will determine how many times the elasticity of the flame of fired powder exceeds the elasticity of common air—supposing it to be confined in the same space which the powder filled before it was fired. Hence then the absolute quantity of the pressure exerted by gunpowder at the moment of its explosion may be assigned; for, since the fluid then generated has an elasticity of 999$\frac{1}{3}$, or, in round numbers, 1000 times greater than that of the atmosphere; and since common air by its elasticity exerts a pressure on any given surface equal to the weight of the incumbent atmosphere with which it is in equilibrio, the pressure exerted by fired powder before it dilated itself is 1000 times greater than the pressure of the atmosphere; and, consequently, the quantity of this force, on a surface of an inch square, amounts to above six tons weight, which force, however, diminishes as the fluid dilates itself."

The method adopted by Robins for determining the elastic force of the gas produced by the ignition of gunpowder, when reduced to the ordinary temperature of the air, was independent of the actual nature of the gas, and therefore unaffected by the erroneous views then entertained respecting it. In fact, the weight of the gases, instead of being only three-tenths of the weight of the powder, is about six-tenths of that weight; and by the estimate of Gay Lussac, the proportion between the space occupied by the gases and by the powder would be nearly double that adopted by Robins. Gay Lussac obtained from 100 grammes of powder 50 litres of gas, and as the 100 grammes, of density 0·9, would have occupied one-ninth of a litre, the elastic force of the gas, when compressed in that space, would be $50 \times 9 = 450$: and Captain Boxer, reasoning upon the known composition of gunpowder and the theoretical results of its decomposition as a definite chemical compound, makes it 317$\frac{1}{2}$; but as experience has shown that these results are by no means confined to the theoretical products, it is probable that the determination of Gay Lussac is very near the truth. In like manner, the estimate of the temperature produced by the ignition of gunpowder has been variously stated, as well as the resulting elastic force: thus Gay Lussac assumes the temperature at 1000° Cent., or 1832 Fahr., and the resulting elastic pressure as 2137 atmospheres; Piobert assumed a temperature more than double that stated by Gay Lussac, and arrived at a pressure of 7500 atmosphere; but, as observed by Senderos (1852), it is impossible to determine with accuracy in this manner the impulsive force of the gases produced from the ignition of gunpowder, though, without doubt, it greatly exceeds that stated by Robins, as will be pointed out hereafter.

Having thus determined the force of the gunpowder, Mr Robins next proceeds to determine the velocity with which the ball is discharged, adopting in the solution of this problem, the two following principles, neither of which is strictly correct,—1. That the action of the powder on the bullet ceases as soon as the bullet leaves the piece. 2. That all the powder of the charge is fired and converted into elastic fluid before the bullet is sensibly removed from its place.

"The first of these," says Mr Robins, "will appear manifest when it is considered how suddenly the flame will extend itself on every side, by its own elasticity, when it is once got out of the mouth of the piece; for by this means its force will then be dissipated, and the bullet no longer sensibly affected by it.

"The second principle is indeed less obvious, being contrary to the general opinion of almost all writers on this subject. It might, however, be sufficient for the proof of this position, to observe the prodigious compression of the flame in the chamber of the piece. Those who attend to this circumstance, and to the easy passage of the flame through the intervals of the grains, may soon satisfy themselves that no one grain contained in that chamber can continue for any time uninflamed, when thus surrounded and pressed by such an active fire. However, not to rely on mere speculation in a matter of so much consequence, I considered that if part only of the powder is fired, and that successively; then, by laying a greater weight before the charge (suppose two or three bullets instead of one), a greater quantity of powder would necessarily be fired, since a heavier weight would be a longer time in passing through the barrel. Whence it should follow that two or three bullets would be impelled by a much greater force than one only. But the contrary to this appears by experiment; for, firing one, two, and three bullets laid contiguous to each other with the same charge respectively, I have found that their velocities were not much different from the reciprocal of their subduplicate quantities of matter; that is, if a given charge would communicate to one bullet a velocity of 1700 feet in a second, the same charge would communicate to two bullets a velocity of from 1250 to 1300 feet in a second, and to three bullets a velocity of from 1050 to 1110 feet in the same time. From hence it appears, that whether a piece is loaded with a greater or less weight of bullet, the action is nearly the same. The excess of the velocities of the two and three bullets above what they ought to have been by this rule (which are that of 1200 and 980 feet in a second), undoubtedly arises from the flame, which, escaping by the side of the first bullet, acts on the surface of the second and third. Now this excess has in many experiments been imperceptible, and the velocities have been reciprocally in the subduplicate ratios of the number of bullets, to sufficient exactness; and where this error has been greater, it has never arisen to an eighth part of the whole; but if the common opinion was true, that a small part only of the powder fires at first, and other parts of it successively as the bullet passes through the barrel, and that a considerable part of it is often blown out of the piece without firing at all, then the velocity which three bullets received from the explosion ought to have been much greater than we have found it to be."

"With respect to the grains of powder which are often blown out unfired, and which are always urged as a proof of the gradual firing of the charge, there may perhaps be some few grains in the best powder of such an heterogeneous composition as to be less susceptible of firing; which, I think, I have myself observed; and these, though they are surrounded by the flame, may be driven out unfired."

Such were the reasonings of Mr Robins; but however rapid the ignition of gunpowder, it is still progressive; and without doubt the ball moves before the whole impulse of the powder from its complete ignition has been received, and it is equally certain that some portion, however small, of the powder is generally thrown out unburnt. Were it not indeed for the movement of the ball before the full development of the elastic force of the gases, accidents from the bursting of guns would be frequent, as may be judged from the consequence of any impediment in the way of the movement of the ball, or from accidentally leaving it at a distance from the charge. Senderos observes—"The full force of gunpowder, with the intensity it possesses, is not used in fire-arms, but only a small part of it. It is undoubted that the transmission of any force requires time. The projectile opposes a resistance proportioned to its mass or inertia, and as soon as the force has become sufficient to overcome that resistance, the projectile begins to move, and allows the gases to expand into a larger space, thus losing density and caloric before they exert their full force on the gun."

"These postulates being allowed to be just, let AB, fig. 6, represent the axis of any piece of artillery; A the breech, and B the muzzle; DC the diameter of its bore, and DEGC a part of its cavity filled with powder. Suppose the ball that is to be impelled to lie with its hinder surface at the line GE; then the pressure exerted at the explosion on the circle of which GE is the diameter, or, which is the same thing, the pressure exerted in the direction FB on the surface of the ball is easily known from the known dimensions of that circle. Draw any line FH perpendicular to FB, and AI parallel to FH; and through the point H to the asymptotes IA and AB, describe the hyperbola KHNQ; then, if FH represents the force impelling the ball at the point F, the force impelling the ball at any other point, as at M, will be represented by the line MN, the ordinate to the hyperbola at that point. For when the fluid impelling the body along has dilated itself to M, its density will be then to its original density in the space DEGC reciprocally as the spaces through which it is extended—that is, as FA to MA, or as MN to FH; but it has been shown that the impelling force or elasticity of this fluid is directly as its density, therefore, if FH represents the force at the point F, MN will represent the like force at the point M.

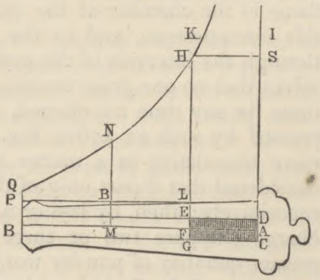

Fig. 6.

"Since the absolute quantity of the force impelling the ball at the point F is known, and the weight of the ball is also known, the proportion between the force with which the ball is impelled and its own gravity is known. In this proportion take FH to FL, and draw LP parallel to FB; then, MN the ordinate to the hyperbola in any point will be to its part MR, cut off by the line LP, as the impelling force of the powder in that point M to the gravity of the ball; and consequently the line LP will determine a line proportional to the uniform force of gravity in every point; whilst the hyperbola HNQ determines in like manner such ordinates as are proportional to the impelling force of the powder in every point; whence, by the 39th Prop. of lib. i. of Sir Isaac Newton's *Principia*, the areas FLPB and FHQB are in the duplicate proportion of the velocities which the ball would acquire when acted upon by its own gravity through the space FB, and when impelled through the same space by the force of the powder. But since the ratio of AF to AB and the ratio of FH to FL are known, the ratio of the area FLPB to the area FHQB is known; and thence its subduplicate. And since the line FB is given in magnitude, the velocity which a heavy body would acquire when impelled through this line by its own gravity is known; being no other than the velocity it would acquire by falling through a space equal to that line: find then another velocity to which this last-mentioned velocity bears the given ratio of the subduplicate of the area FLPB to the area FHQB; and this velocity thus found is the velocity the ball will acquire when impelled through the space FB by the action of the inflamed powder.

"Now, to give an example of this: Let us suppose AB, the length of the cylinder, to be 45 inches; its diameter DC, or rather the diameter of the ball, to be $\frac{3}{4}$ths of an inch; and AF, the extent of the powder, to be $2\frac{1}{8}$th inches; to determine the velocity which will be communicated to a leaden bullet by the explosion, supposing the bullet to be laid at first with its surface contiguous to the powder.

"By the theory we have laid down, it appears, that at the first instant of the explosion the flame will exert, on the bullet lying close to it, a force 1000 times greater than the pressure of the atmosphere. The medium pressure of the atmosphere is reckoned equal to a column of water 33 feet in height; whence, lead being to water as 11·345 to 1, this pressure will be equal to that of a column of lead 3·49 inches in height. Multiplying this by 1000, therefore, a column of lead 34,900 inches (upwards of half a mile) in height, would produce a pressure on the bullet equal to what is exerted by the powder in the first instant of the explosion; and the leaden ball being $\frac{3}{4}$ths of an inch in diameter, and consequently equal to a cylinder of lead of the same base half an inch in height, the pressure at first acting on it will be equal to 34,900 × 2, or 69,800 times its weight; whence FL to FH is as 1 to 69,800; and FB to FA as $45 - 2\frac{5}{8}$, or $42\frac{3}{8}$ to $2\frac{5}{8}$, that is, as 339 to 21; whence the rectangle FLPB is to the rectangle AFHS as 339 to 21 × 69,800, that is, as 1 to 4324. And from the known application of the logarithms to the mensuration of the hyperbolic spaces, it follows that the rectangle AFHS is to the area FHQB as ·43429, &c., is to the tabular logarithm of $\frac{AB}{AF}$; that is, of $\frac{360}{21}$, which is 1·2340579: whence the ratio of the rectangle FLPB to the hyperbolic area FHQB is compounded of the ratios of 1 to 4324—and of ·43429, &c., to 1·2340579; which together make up the ratio of 1 to 12263, the subduplicate of which is the ratio of 1 to 110·7; and in this ratio is the velocity which the bullet would acquire by gravity in falling through a space equal to FB, to the velocity the bullet will acquire from the action of the powder impelling it through FB. But the space FB being $42\frac{3}{8}$ inches, the velocity a heavy body will acquire in falling through such a space is known to be what would carry it nearly at the rate of 15·07 feet in a second; whence the velocity to which this has the ratio of 1 to 110·7 is a velocity which would carry the ball at the rate of 1668 feet in one second. And this is the velocity which, according to the theory, the bullet in the present circumstances would acquire from the action of the powder during the time of its dilatation.

"Now this velocity being once computed for one case, is easily applied to any other; for if the cavity DEGC left behind the bullet be only in part filled with powder, then the line HF, and consequently the area FHQB, will be diminished in the proportion of the whole cavity to the part filled. If the diameter of the bore be varied, the lengths AB and AF remaining the same, then the quantity of powder and the surface of the bullet which it acts on will be varied in the duplicate proportion of the diameter, but the weight of the bullet will vary in the triplicate proportion of the diameter; wherefore the line FH, which is directly as the absolute impelling force of the powder, and reciprocally as the gravity of the bullet, will change in the reciprocal proportion of the diameter of the bullet. If AF, the height of the cavity left behind the bullet, be increased or diminished, the rectangle of the hyperbola, and consequently the area corresponding to ordinates in any given ratio, will be increased or diminished in the same proportion. From all which it follows, that the area FHQB, which is in the duplicate proportion of the velocity of the impelled body, will be directly as the logarithm$\frac{AB}{AF}$ (where AB represents the length of the barrel, and AF the length of the cavity left behind the bullet); also directly as the part of that cavity filled with powder, and inversely as the diameter of the bore, or rather of the bullet; likewise directly as AF, the height of the cavity left behind the bullet. Consequently the velocity being computed as above, for a bullet of a determined diameter, placed in a piece of a given length, and impelled by a given quantity of powder, occupying a given cavity behind that bullet; it follows, that by means of these ratios, the velocity of any other bullet may be thence deduced; the necessary circumstances of its position, quantity of powder, &c., being given. Where note, that in the instance of this supposition, we have supposed the diameter of the ball to be $\frac{3}{4}$ths of an inch; whence the diameter of the bore will be something more, and the quantity of powder contained in the space DEGC will amount exactly to twelve pennyweights, a small wad of tow included.

"In order to compare the velocities communicated to bullets by the explosion, with the velocities resulting from the theory by computation, it is necessary that the actual velocities with which bullets move should be discovered. The only methods hitherto practised for this purpose, have been either by observing the time of the flight of a shot through a given space, or by measuring the range of a shot at a given elevation; and thence computing, on the parabolic hypothesis, what degree of velocity would produce this range. The first method labours under this insurmountable difficulty, that the velocities of these bodies are often so swift, and consequently the time observed is so short, that an imperceptible error in that time may occasion an error in the velocity thus found of 200, 300, 400, 500, or 600 feet, in a second. The other method is so fallacious, by reason of the resistance of the atmosphere (to which inequality the first is also liable), that the velocities thus assigned may not perhaps be the tenth part of the actual velocities sought.

"The simplest method of determining this velocity is by means of the instrument (the *Ballistic Pendulum*), represented in fig. 7, where ABCD represents the body of the machine composed of the three poles B, C, D, spreading at bottom, and joining together at the top A; being the same with what is vulgarly used in lifting and weighing very heavy bodies, and is called by workmen the triangles. On two of these poles, towards their tops, are screwed on the sockets R, S; and on these sockets the pendulum EFGHIK is hung by means of its cross-piece EF, which becomes its axis of suspension, and on which it must be made to vibrate with great freedom. The body of this pendulum is made of iron, having a broad part at bottom, and its lower part is covered with a thick piece of wood GKIH, which is fastened to the iron by screws. Something lower than the bottom of the pendulum there is a brace OP, joining the two poles from which the pendulum is suspended; and to this brace there is fastened a contrivance MNU, made with two edges of steel, bearing on each other in the line UN, something in the manner of a drawing-pen; the strength with which these edges press on each other being diminished or increased at pleasure by means of a screw Z going through the upper piece. There is fastened to the bottom of the pendulum a narrow ribbon LN, which passes between these steel edges, and which afterwards, by means of an opening cut in the lower piece of steel, hangs loosely down, as at W.

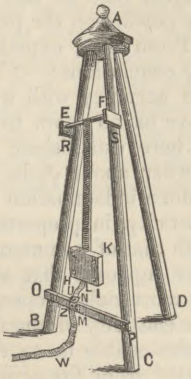

Fig. 7.

"With this apparatus, if the weight of the pendulum be known, and likewise the respective distances of its centre of gravity and of its centre of oscillation from its axis of suspension, it will thence be known what motion will be communicated to this pendulum by the percussion of a body of a known weight moving with a known degree of celerity, and striking it in a given point; that is, if the pendulum be supposed at rest before the percussion, it will be known what vibration it ought to make in consequence of such a determined blow; and, on the contrary, if the pendulum, being at rest, is struck by a body of a known weight, and the vibration which the pendulum makes after the blow is known, the velocity of the striking body may from thence be determined. Hence, then, if a bullet of a known weight strikes the pendulum, and the vibration which the pendulum makes in consequence of the stroke be ascertained, the velocity with which the ball moved is thence to be known.

"Now the extent of the vibration made by the pendulum after the blow, may be measured to great accuracy by the ribbon LN. For let the pressure of the edges UN on the ribbon be so regulated by the screw Z, that the motion of the ribbon between them may be free and easy, though with some minute resistance; then, settling the pendulum at rest, let the part LN between the pendulum and the edges be drawn strait, but not strained, and fix a pin in that part of the ribbon which is then contiguous to the edges: let now a ball impinge on the pendulum; then the pendulum swinging back will draw out the ribbon to the just extent of its vibration, which will consequently be determined by the interval on the ribbon between the edges UN and the place of the pin.

"The weight of the whole pendulum, wood and all, was 56 pounds 3 ounces; its centre of gravity was 52 inches distant from its axis of suspension, and 200 of its small swings were performed in the time of 253 seconds; whence its centre of oscillation is 62$\frac{2}{3}$d inches distant from that axis. The centre of the piece of wood GKIH is distant from the same axis 66 inches. In the compound ratio of 66 to 62$\frac{2}{3}$d, and 66 to 52, take the quantity of matter of the pendulum to a fourth quantity, which will be 42 lbs. $\frac{1}{2}$ oz. Now geometers well know, that if the blow be struck on the centre of the piece of wood GKIH, the pendulum will resist to the stroke in the same manner as if this last quantity of matter only (42 lbs. $\frac{1}{2}$ oz.) was concentrated in that point, and the rest of the pendulum was taken away: whence, supposing the weight of the bullet impinging in that point to be the $\frac{1}{12}$th of a pound, or the $\frac{1}{505}$th of this quantity of matter nearly, the velocity of the point of oscillation after the stroke will, by the laws observed in the congress of such bodies as rebound not from each other, be the $\frac{1}{505}$th of the velocity the bullet moved with before the stroke; whence the velocity of this point of oscillation after the stroke being ascertained, that multiplied by 505 will give the velocity with which the ball impinged.

"But the velocity of the point of oscillation after the stroke is easily deduced from the chord of the arch through which it ascends by the blow; for it is a well-known proposition, that all pendulous bodies ascend to the same height by their vibratory motion as they would do if they were projected directly upwards from their lowest point, with the same velocity they have in that point; wherefore, if the versed sine of the ascending arch be found (which is easily determined from the chord and radius being given), this versed sine is the perpendicular height to which a body projected upwards with the velocity of the point of oscillation would arise; and consequently what that velocity is, can be easily computed by the common theory of falling bodies.

"For instance, the chord of the arch, described by the ascent of the pendulum after the stroke measured on the ribbon, has been sometimes 17$\frac{1}{4}$th inches; the distance of the ribbon from the axis of suspension is 71$\frac{1}{8}$th inches; whence reducing 17$\frac{1}{4}$th in the ratio of 71$\frac{1}{8}$th to 66, the resulting number, which is nearly 16 inches, will be the chord of the arch through which the centre of the board GKIH ascended after the stroke; now the versed sine of the arch, whose chord is 16 inches, and its radius 66, is 1·93939; and the velocity which would carry a body to this height, or, which is the same thing, the velocity which a body would acquire by descending through this space, is nearly that of 3$\frac{1}{4}$th feet in 1^s.

"To determine then the velocity with which the bullet impinged on the centre of the wood, when the chord of the arch described by the ascent of the pendulum, in consequence of the blow, was 17$\frac{1}{4}$th inches measured on the ribbon, no more is necessary than to multiply 3$\frac{1}{4}$th by 505, and the resulting number, 1641, will be the feet which the bullet would describe in 1^s, if it moved with the velocity it had at the moment of its percussion; for the velocity of the point of the pendulum on which the bullet struck, we have just now determined to be that of 3$\frac{1}{4}$th feet in 1^s; and we have before shown that this is the $\frac{1}{505}$th of the velocity of the bullet. If then a bullet weighing $\frac{1}{12}$th of a pound strikes the pendulum in the centre of the wood GKIH, and the ribbon be drawn out 17$\frac{1}{4}$th inches by the blow, the velocity of the bullet is that of 1641 feet in 1^s. And since the length the ribbon is drawn is always nearly the chord of the arch described by the ascent (it being placed so as to differ insensibly from those chords which most frequently occur), and these chords are known to be in the proportion of the velocities of the pendulum acquired from the stroke; it follows that the proportion between the lengths of ribbon drawn out at different times will be the same with that of the velocities of the impinging bullets; and consequently, by the proportion of these lengths of ribbon to 17$\frac{1}{4}$th, the proportion of the velocity with which the bullets impinge, to the known velocity of 1641 feet in 1^s, will be determined. Hence then is shown in general how the velocities of bullets of all kinds may be found out by means of this instrument."

Mr Robins then gave several precautionary rules for securing precision in the experiments, and guarding against accidents, amongst which were the two following:—

"The weight of the pendulum and the thickness of the wood necessary to prevent the bullets from being shivered by striking directly on the iron, must be in some measure proportioned to the size of the bullets which are used. A pendulum of the weight here described will do very well for all bullets under three or four ounces, if the thickness of the board be increased to seven or eight inches for the heaviest bullets. Beech is the toughest and properest wood for this purpose.

"The powder used in these experiments should be exactly weighed; and that no part of it be scattered in the barrel, the piece must be charged with a ladle, in the same manner as is practised with cannon; the wad should be of tow, of the same weight each time, and no more than is just necessary to confine the powder in its proper place; the length of the cavity left behind the ball should be determined each time with exactness; for the increasing or diminishing that space will vary the velocity of the shot, although the bullet and quantity of powder be not changed. The distance of the mouth of the piece from the pendulum ought to be such, that the impulse of the flame may not act on the pendulum; this will be prevented in a common barrel charged with half an ounce of powder, if it be at the distance of 16 or 18 feet: in larger charges the impulse is sensible farther off; I have found it to extend to above 25 feet; however, between 25 and 18 feet is the distance I have usually chosen."

With this instrument, or others similar to it, Mr Robins made a great number of experiments on barrels of different lengths, and with different charges of powder. He has given us the results of sixty-one of these; and having compared the actual velocities with the computed ones, his theory appears to have come as near the truth as could well be expected. In seven of the experiments there was a perfect coincidence; the charges of powder being 6 to 12 pennyweights, the barrels 45, 24·312 and 7·06 inches in length. The diameter of the first (marked A) was $\frac{3}{4}$ths of an inch; of the second (B) was the same; and of D, ·83 of an inch. In the first of these experiments, another barrel (C) was used, whose length was 12·375 inches, and the diameter of its bore $\frac{3}{4}$ inch. In fourteen more of the experiments, the difference between the length of the chord of the pendulum's arch shown by the theory and the actual experiment, was $\frac{1}{10}$th of an inch over or under. This showed an error in the theory, varying, according to the different lengths of the chord, from $\frac{1}{171}$th to $\frac{1}{47}$th of the whole; the charges of powder were the same as in the last. In sixteen other experiments the error was $\frac{2}{10}$ths of an inch, varying from $\frac{1}{85}$th to $\frac{1}{15}$th of the whole; the charges of powder were 6, 8, 9, or 12 pennyweights. In seven other experiments the error was $\frac{3}{10}$ths of an inch, varying from $\frac{1}{62}$d to $\frac{1}{23}$d of the whole; the charges of powder 6 or 12 pennyweights. In eight experiments the difference was $\frac{4}{10}$ths of an inch, indicating an error of from $\frac{1}{42}$d to $\frac{1}{23}$d of the whole; the charges being 6, 9, 12, and 24 pennyweights of powder. In three experiments the error was $\frac{5}{10}$ths, varying from $\frac{1}{58}$th to $\frac{1}{12}$th of the whole; the charges 8 and 12 pennyweights of powder. In two experiments the error was $\frac{6}{10}$ths, in one case amounting to something less than $\frac{1}{32}$d, in the other to $\frac{1}{22}$d of the whole; the charges 12 and 36 pennyweights of powder. By one experiment the error was $\frac{7}{10}$ths, and by another $\frac{8}{10}$ths; the first amounting to $\frac{1}{10}$th nearly, the latter to almost $\frac{1}{9}$th of the whole; the charges of powder 6 or 12 pennyweights. The last error, however, Mr Robins ascribes to the wind. The two remaining experiments varied from theory by 1·3 inches, somewhat more than $\frac{1}{9}$th of the whole; the charges of powder were 12 pennyweights in each; and Mr Robins ascribes the error to the dampness of the powder. In another case he ascribes an error of $\frac{6}{10}$ths to the blast of the powder on the pendulum.

From these experiments Mr Robins deduces the following conclusions:—"The variety of these experiments, and the accuracy with which they correspond to the theory, leave us no room to doubt of its certainty. This theory, as here established, supposes that, in the firing of gunpowder, about $\frac{3}{10}$ths of its substance is converted by the sudden inflammation into a permanently elastic fluid, whose elasticity, in proportion to its heat and density, is the same with that of common air in the like circumstances: it farther supposes that all the force exerted by gunpowder in its most violent operations is no more than the action of the elasticity of the fluid thus generated; and these principles enable us to determine the velocities of bullets impelled from fire-arms of all kinds, and are fully sufficient for all purposes where the force of gunpowder is to be estimated.

"From this theory many deductions may be made of the greatest consequence to the practical part of gunnery.

From hence the thickness of a piece, which will enable it to confine, without bursting, any given charge of powder, is easily determined, since the effort of the powder is known; and from it we are taught the necessity of leaving the same space behind the bullet, when we would, by the same quantity of powder, communicate to it an equal degree of velocity; since, on the principles already laid down, it follows that the same powder has a greater or less degree of elasticity, according to the different spaces it occupies. The method which I have always practised for this purpose has been by marking the rammer; and this is a maxim which ought not to be dispensed with when cannon are fired at an elevation, particularly in those called by the French *batteries à ricochet.*

"From the continued action of the powder, and its manner of expanding described in this theory, and the length and weight of the piece, one of the most essential circumstances in the well directing of artillery may be easily ascertained. All practitioners are agreed that no shot can be depended on, unless the piece be placed on a solid platform; for if the platform shakes with the first impulse of the powder, it is impossible but the piece must also shake, which will alter its direction, and render the shot uncertain. To prevent this accident, the platform is usually made extremely firm to a considerable depth backwards; so that the piece is not only well supported in the beginning of its motion, but likewise through a great part of its recoil. However, it is sufficiently obvious that when the bullet is separated from the piece, it can be no longer affected by the trembling of the piece or platform; and, by a very easy computation, it will be found that the bullet will be out of the piece before the latter hath recoiled half an inch.

"If the whole substance of the powder was converted into an elastic fluid at the instant of the explosion, then, from the known elasticity of this fluid assigned by our theory, and its known density, we could easily determine the velocity with which it would begin to expand, and could thence trace out its future augmentations in its progress through the barrel: but as we have shown that the elastic fluid, in which the activity of the gunpowder consists, is only $\frac{3}{10}$ths of the substance of the powder, the remaining $\frac{7}{10}$ths will, in the explosion, be mixed with the elastic part, and will, by its weight, retard the activity of the explosion; and yet they will not be so completely united as to move with one common motion; but the unelastic part will be less accelerated than the rest, and some will not even be carried out of the barrel, as appears by the considerable quantity of unctuous matter which adheres to the inside of all fire-arms after they have been used."

Mr Robins then investigates the cause of these irregularities in the expansive motion of the fluid by experiments; but before referring to them, it is right to observe, as has been before stated, that in British gunpowder, consisting of 75 parts of nitre, 15 of charcoal, and 10 of sulphur, the potassium of the nitre and the sulphur are the only constituents which unite to form a solid residuum, the sulphate of potassium, and that their weight being about 39 lbs. per cent., the remaining 61 lbs., or $\frac{6}{10}$ths of the whole, form gaseous elastic products.

> "The experiments made use of for this purpose were of two kinds. The first was made by charging a barrel A with 12 pennyweights of powder, and a small wad of tow only; and then placing its mouth 19 inches from the centre of the pendulum. On firing it in this situation, the impulse of the flame made it ascend through an arch whose chord was 13·7 inches; whence, if the whole substance of the powder was supposed to strike against the pendulum, and each part to strike with the same velocity, that common velocity must have been at the rate of about 2650 feet in a second. But, as some part of the velocity of the flame was lost in passing through 19 inches of air, I made the remaining experiments in a manner not liable to this inconvenience.
>
> "I fixed the barrel A on the pendulum, so that its axis might be both horizontal and also perpendicular to the plane HK; or, which is the same thing, that it might be in the plane of the pendulum's vibration; the height of the axis of the piece above the centre of the pendulum was 6 inches, and the weight of the piece, and of the iron that fastened it, &c., was 12½ lbs. The barrel in this situation being charged with 12 pennyweights of powder, without either ball or wad, only put together with the rammer; on the discharge the pendulum ascended through an arch whose chord was 10 inches, or, reduced to an equivalent blow in the centre of the pendulum, supposing the barrel away, it would be 14·4 inches nearly. The same experiment being repeated, the chord of the ascending arch was 10·1 inches, which, reduced to the centre, is 14·6 inches.
>
> "To determine what difference of velocity there was in the different parts of the vapour, I loaded the piece again with 12 pennyweights of powder, and rammed it down with a wad of tow weighing 1 pennyweight. Now, I conceived that this wad, being very light, would presently acquire that velocity with which the elastic part of the fluid would expand itself when uncompressed; and I accordingly found that the chord of the ascending arch was by this means increased to 12 inches, or at the centre to 17·3; whence, as the medium of the other two experiments is 14·5, the pendulum ascended through an arch 2·8 inches longer, by the additional motion of 1 pennyweight of matter, moving with the velocity of the swiftest part of the vapour; and, consequently, the velocity with which this pennyweight of matter moved was that of about 7000 feet in a second."

Mr Robins here adduces some experiments to obviate a possible objection by showing that the confinement of the powder was not necessary to ensure its total ignition and the full development of its elastic force, and "that the push of the recoil, arising from the *expansion of the powder alone*, is found to be no greater when it impels a leaden bullet before it than when the same quantity is forced without any wad to confine it;" and then proceeds as follows:—

> "Again, that this velocity of 7000 feet in a second is not much beyond what the most active part of the flame acquires in expanding, is evinced from hence, that in some experiments a ball has been found to be discharged with a velocity of 2400 feet in a second, and yet it appeared not that the action of the powder was at all diminished on account of this immense celerity; consequently, the degree of swiftness with which, in this instance, the powder followed the ball without losing any part of its pressure, must have been much short of what the powder alone would have expanded with had the ball not been there.
>
> "From these determinations may be deduced the force of petards, since their action depends entirely on the impulse of the flame; and it appears that a quantity of powder properly disposed in such a machine may produce as violent an effort as a bullet of twice its weight, moving with a velocity of 1400 or 1500 feet in a second."

However ingenious the researches of Mr Robins into this important element of gunnery—the velocity with which the gases produced by the ignition of gunpowder expand—they have not been admitted by some as satisfactorily solving the question; and yet Hutton, although, by a combination of experiment and calculation, he had deduced a velocity varying from 3000 to 5000 feet, after correcting one of the quantities in his formula, at first assumed too high, arrived at a conclusion very nearly the same as the experimental one of Robins. The determination, indeed, of the velocity of the elastic gases is attended with much difficulty, as is that (as before pointed out) of the initial force with which these gases act upon the projectile they are intended to propel. Robins considered this force to be about 1000 atmospheres; but Hutton found it to vary, according to the charge and the length of gun, from 1700 to 2300, and he therefore considers it as fairly represented by about 2000 atmospheres, and his results were confirmed by those of Dr Gregory, who made it 2250. Now, Hutton's formula for determining the ultimate velocity of the ball, and consequently of the gas then pressing against and urging it forward, is

$$V = 46{\cdot}7\sqrt{\frac{nhd^2}{p+w} \times \log.\frac{b}{a}} = 46{\cdot}7\,d\sqrt{\frac{nh}{p+w} \times \log.\frac{b}{a}};$$

where a represents the height or length of the charge, including cartridge, or of the space behind the ball, b the whole length of the gun-bore, h the length of the portion of the cylinder or bore which would be filled with the powder, d the diameter of the ball or of the bore, n the ratio of the first force of the fired powder to the pressure of the atmosphere as 1, w the weight of the ball, and p a quantity having some fixed relation to the weight of the charge; and if in this formula the weight of the ball be made 0, V becomes the value of the velocity of the expanding gas. But here enters a difficulty, as it is not easy to determine what proportion of the weight of the powder ought to be assumed for p, from the uncertainty of the actual condition of the gases and of the solid residuum, at the moment of decomposition of the powder. Supposing an equal density to exist throughout the bulk of the gases, and that the solid residuum is diffused equally through them, p should be, as Hutton at first assumed it, $\frac{1}{2}$ of the weight of the powder; but, as it is more probable that the rear portion of the gas is much more condensed than the front portion, and, consequently, that the centre of gravity of the whole gas has moved through a still less space, p must be taken less than $\frac{1}{2}$, and in this manner Hutton found that the velocity of the gases, when p was taken as $\frac{1}{3}$ of the weight of the powder, became between 7000 and 8000 feet per second; and when taken $\frac{1}{2}$, from 3000 to 5000—results sufficient in themselves to prove how impossible almost it must be to determine theoretically the velocity of the gases. In investigating the decomposition of gunpowder, there are two points to be taken into consideration—the velocity of ignition, and the velocity of combustion; or, in other words, the time required to burn each grain of powder, on the one hand, and the time necessary for communicating ignition, as the flame is conveyed by the expanding gases with great rapidity from one grain to another. Piobert has endeavoured to estimate the velocity of combustion independently of that of ignition by forming a kind of bar with a paste of powder, 1 foot 2 inches in length, and about $\frac{9}{10}$ths of an inch square, the bar being smeared with fine hog's lard, and placed vertically on a plate with water. This bar, weighing 330 grammes, was ignited at the top, and required 29·2 seconds for combustion, being at the rate of ·486 of an inch per second. By other experiments of the same author, powder inclosed and slightly compressed in a tube $\frac{3}{4}$ths of an inch in diameter and open at one end, burnt at the rate of ·3 of an inch per second, or, when strongly compressed, at the rate of ·4 to ·6 of an inch per second. From these statements it is evident that, however rapid the combustion of powder, it is not instantaneous; and that the great object is to facilitate the transmission of the flame through the powder so as to render the ignition of the whole as nearly simultaneous as possible. The process of granulating powder for this purpose was early introduced, as Luis Collado, before mentioned, expressly points out the greater force of powder when grained as compared to that of its meal; and Cyprian Lucar explains the mode of graining or "corning" the powder by passing it through sieves after having broken up the cake which had been first formed in the incorporating process. The size of the grain is an important element, and ought to be so arranged as to reduce the time of combustion to the minimum consistent with a due rapidity of ignition; and more particularly so as the denser the powder the greater quantity of gas must be produced at the same space, and the greater therefore the elastic force developed; whilst, as regards the *grain itself*, anything which increases its density must increase the velocity of ignition and diminish that of combustion, whilst the rapidity of combustion increases as the grains are more porous and less smooth. These observations sufficiently demonstrate that the combustion of the charge cannot be effected in less time than that required for the combustion of a grain; but in this respect it must be remembered that the combustion proceeds from the circumference to the centre, and therefore requires only half the time as compared with Piobert's experiments. If, then, each grain were $\frac{1}{10}$th of an inch in diameter, the complete combustion would be effected in $\frac{1}{10}$th of a second; and if $\frac{1}{20}$th, in $\frac{1}{20}$th of a second; but long before that time the quantity of gas evolved must have been sufficient to move the ball, its ultimate velocity depending on the time it remains in the bore, or, in other words, on the more complete combustion of the powder, as well as on the continuance of the action of the gases produced.

"In many of the experiments already recited the ball was not laid immediately contiguous to the powder, but at a small distance, amounting, at the utmost, only to $1\frac{1}{2}$ inch. In these cases the theory agreed very well with the experiments. But if a bullet is placed at a greater distance from the powder—suppose at 12, 18, or 24 inches—we cannot then apply to this ball the same principles which may be applied to those laid in contact, or nearly so, with the powder; for, when the surface of the fired powder is not confined by a heavy body, the flame dilates itself with a velocity far exceeding that which it can communicate to a bullet by its continued pressure; consequently, as, at the distance of 12, 18, or 24 inches, the powder will have acquired a considerable degree of this velocity of expansion, the first motion of the ball will not be produced by the continued pressure of the powder, but by the actual percussion of the flame; and it will therefore begin to move with a quantity of motion proportioned to the quantity of this flame, and the velocities of its respective parts.

"From hence, then, it follows, that the velocity of the bullet, laid at a considerable distance before the charge, ought to be greater than what would be communicated to it by the pressure of the powder acting in the manner already mentioned; and this deduction from our theory we have confirmed by manifold experience, by which we have found that a ball laid in the barrel A, with its hinder part $11\frac{1}{4}$ inches from its breech, and impelled by 12 pennyweights of powder, has acquired a velocity of about 1400 feet in a second; when, if it had been acted on by the pressure of the flame only, it would not have acquired a velocity of 1200 feet in a second. The same we have found to hold true in all other greater distances (and also in lesser, though not in the same degree), and in all quantities of powder; and we have likewise found, that these effects nearly correspond with what has been already laid down about the velocity of expansion and the elastic and unelastic parts of the flame.

"From hence, too, arises another consideration of great consequence in the practice of gunnery; which is, that no bullet should at any time be placed at a considerable distance from the charge, unless the piece is extremely well fortified; for a moderate charge of powder, when it has expanded itself through the vacant space, and reaches the ball, will, by the velocity each part has acquired, accumulate itself behind the ball, and thereby be condensed prodigously; whence, if the barrel be not extremely firm in that part, it must, by means of this reinforced elasticity, infallibly burst. The truth of this reasoning I have experienced in an exceeding good Tower musket, forged of very tough iron; for, charging it with 12 pennyweights of powder, and placing the ball 16 inches from the breech, on firing it the part of the barrel just behind the bullet was swelled out to double its diameter, like a blown bladder, and two large pieces of 2 inches long were burst out of it.

"Having seen that the entire motion of a bullet laid at a considerable distance from the charge is acquired by two different methods in which the powder acts on it, the first being the percussion of the parts of the flame with the velocity they had respectively acquired by expanding, the second the continued pressure of the flame through the remaining part of the barrel, I endeavoured to separate these different actions, and to retain that only which arose from the continued pressure of the flame. For this purpose I no longer placed the powder at the breech, from whence it would have full scope for its expansion; but I scattered it as uniformly as I could through the whole cavity left behind the bullet; imagining that by this means the progressive velocity of the flame in each part would be prevented by the expansion of the neighbouring parts: and I found, that the ball being laid 11$\frac{1}{4}$ inches from the breech, its velocity, instead of 1400 feet in a second, which it acquired in the last experiments, was now no more than 1100 feet in the second, which is 100 feet short of what, according to the theory, should arise from the continued pressure of the powder only.

"The reason of this deficiency was, doubtless, the intestine motion of the flame; for the ascension of the powder thus distributed through so much larger a space than it could fill, must have produced many reverberations and pulsations of the flame; and from these internal agitations of the fluid, its pressure on the containing surface will (as in the case of all other fluids) be considerably diminished; and in order to avoid this irregularity, in all other experiments I took care to have the powder closely confined in as small a space as possible, even when the bullet lay at some distance from it.

"With regard to the resistance of the air, which so remarkably affects all military projectiles, it is necessary to premise, that the greatest part of authors have established it as a certain rule, that while the same body moves in the same medium, it is always resisted in the duplicate proportion of its velocity; that is, if the resisted body move in one part of its track with three times the velocity with which it moved in some other part, then its resistance to the greater velocity will be nine times the resistance to the lesser. If the velocity in one place be four times greater than in another, the resistance of the fluid will be sixteen times greater in the first than in the second, &c. This rule, however, though pretty near the truth when the velocities are confined within certain limits, is excessively erroneous when applied to military projectiles, where such resistances often occur as could scarcely be effected, on the commonly received principles, even by a treble augmentation of its density.

"By means of the machine already described, I have it in my power to determine the velocity with which a ball moves in any part of its track, provided I can direct the piece in such a manner as to cause the bullet to impinge on the pendulum placed in that part; and therefore, charging a musket barrel three times successively with a leaden ball three-fourths of an inch in diameter, and about half its weight of powder, and taking such precaution in weighing of the powder and placing it, that I was assured, by many previous trials, that the velocity of the ball could not differ by twenty feet in a second from its medium quantity, I fired it against the pendulum placed at 25, 75, and 125 feet distance from the mouth of the piece respectively; and I found that it impinged against the pendulum, in the first case, with a velocity of 1670 feet in a second; in the second case, with a velocity of 1550 feet in a second, and in the third case, with a velocity of 1425 feet in a second; so that, in passing through fifty feet of air, the bullet lost a velocity of 120 or 125 feet in a second; and the time of its passing through that space being about $\frac{1}{32}$d or $\frac{1}{30}$th of a second, the medium quantity of resistance must, in these instances, have been about 120 times the weight of the ball, which (as the ball was nearly $\frac{1}{12}$th of a pound) amounts to about 10 lbs. avoirdupois.

"Now, if a computation be made according to the method laid down for compressed fluids in the 38th Proposition of Newton's *Principia*, supposing the weight of water to that of air as 850 to 1, it will be found that the resistance to a globe of three-fourths of an inch diameter, moving with a velocity of about 1600 feet in a second, will not, on these principles, amount to any more than 4$\frac{1}{2}$ lbs. avoirdupois; whence, as we know that the rules contained in that proposition are very accurate with regard to slow motions, we may hence conclude, that the resistance of the air in slow motions is less than that in swift motions, in the ratio of 4$\frac{1}{2}$ to 10; a proportion between that of one to two and one to three.

"Again, I charged the same piece a number of times with equal quantities of powder, and balls of the same weight, taking all possible care to give to every shot an equal velocity; and firing three times against the pendulum placed only 25 feet from the mouth of the piece, the medium of the velocities with which the ball impinged was nearly that of 1690 feet in a second: then removing the piece 175 feet from the pendulum, I found, taking the medium of five shots, that the velocity with which the ball impinged at this distance was 1300 feet in a second; whence the ball, in passing through 150 feet of air, lost a velocity of about 390 feet in a second: and the resistance computed from these numbers comes out something more than in the preceding instance, it amounting here to between 11 and 12 pounds avoirdupois; whence, according to these experiments, the resisting power of the air to swift motions is greater than to slow ones, in a ratio which approaches nearer to that of 3 to 1 than in the preceding experiments.

"Having thus examined the resistance to a velocity of 1700 feet in a second, I next examined the resistance to smaller velocities; and for this purpose I charged the same barrel with balls of the same diameter, but with less powder, and placing the pendulum at 25 feet distance from the piece, I fired against it five times with an equal charge each time; the medium velocity with which the ball impinged was that of 1180 feet in a second; then, removing the pendulum to the distance of 250 feet, the medium velocity of five shots, made at this distance, was that of 950 feet in a second; whence the ball, in passing through 225 feet of air, lost a velocity of 230 feet in a second; and as it passed through that interval in about $\frac{3}{14}$ths of a second, the resistance to the middle velocity will come out to be near 33$\frac{1}{2}$ times the gravity of the ball, or 2 lbs. 10 oz. avoirdupois. Now, the resistance to the same velocity, according to the laws observed in slower motions, amounts to $\frac{7}{11}$ths of the same quantity; whence, in a velocity of 1065 feet in a second, the resisting power of the air is augmented in no greater proportion than that of 7 to 11; whereas we have seen in the former experiments, that to still greater degrees of velocity the augmentation approached very near the ratio of 1 to 3.

"But farther, I fired three shot, of the same size and weight with those already mentioned, over a large piece of water; so that their dropping into the water being very discernible, both the distance and time of their flight might be accurately ascertained. Each shot was discharged with a velocity of 400 feet in a second; and I had satisfied myself, by many previous trials of the same charge with the pendulum, that I could rely on this velocity to ten feet in a second. The first shot flew 313 yards in 4$\frac{1}{4}$ seconds, the second flew 319 yards in 4 seconds, and the third 373 yards in 5$\frac{1}{4}$ seconds. According to the theory of resistance established for slow motions, the first shot ought to have spent no more than 3·2 seconds in its flight, the second 3·28, and the third 4 seconds; whence it is evident that every shot was retarded considerably more than it ought to have been had that theory taken place in its motion; consequently the resistance of the air is very sensibly increased, even in such a small velocity as that of 400 feet in a second.

"From the computations and experiments already mentioned, it plainly appears that a leaden ball of $\frac{3}{4}$ths of an inch diameter, and weighing nearly 1$\frac{1}{3}$ ounce avoirdupois, if it be fired from a barrel of forty-five inches in length, with half its weight of powder, will issue from that piece with a velocity which, if it were uniformly continued, would carry it near 1700 feet in a second. If, instead of the leaden ball, an iron one, of an equal diameter, was placed in the same situation in the same piece, and was impelled by an equal quantity of powder, the velocity of such an iron bullet would be to that of a leaden one reciprocally in the subduplicate ratio of the specific gravities of lead and iron; and supposing that ratio to be as three to two, and computing on the principles already laid down, it will appear, that an iron bullet of 24 lbs. weight, shot from a piece of ten feet in length, with 16 lbs. of powder, will acquire from the explosion a velocity which, if uniformly continued, would carry it nearly 1650 feet in a second.

"This is the velocity which, according to our theory, a cannon ball of 24 lbs. weight is discharged with when it is impelled by a full charge of powder; but if, instead of a quantity of powder weighing two-thirds of the ball, we suppose the charge to be only half the weight of it, then its velocity will on the same principles be no more than 1490 feet in a second. The same would be the velocities of every lesser bullet fired with the same proportions of powder, if the lengths of all pieces were constantly in the same ratio with the diameters of their bore; and although, according to the usual dimensions of the smaller pieces of artillery, this proportion does not always hold, yet the difference is not great enough to occasion a very great variation from the velocities here assigned, as will be obvious to any one who shall make a computation thereon. But in these determinations we suppose the windage to be no more than is just sufficient for putting down the bullet easily: whereas, in real service, either through negligence or unskilfulness, it often happens that the diameter of the bore so much exceeds the diameter of the bullet, that great part of the inflamed fluid escapes by its side; whence the velocity of the shot in this case may be considerably less than what we have assigned. However, this perhaps may be compensated by the greater heat which in all probability attends the firing of these large quantities of powder.

"It has been already shown, that the resistance of the air on the surface of a bullet of three-fourths of an inch diameter, moving with a velocity of 1670 feet in a second, amounted to about ten pounds. It hath also been shown, that an iron bullet weighing twenty-four pounds, if fired with sixteen pounds of powder (which is usually esteemed its proper battering charge), acquires a velocity of about 1650 feet in a second, scarcely differing from the other; whence, as the surface of this last bullet is more than fifty-four times greater than the surface of a bullet of three-fourths of an inch diameter, and their velocities are nearly the same, it follows, that the resistance on the larger bullet will amount to more than 540 pounds, which is near twenty-three times its own weight.

"Now, the prodigious resistance of the air to a bullet of twenty-four pounds weight, such as we have here established it, sufficiently shows how erroneous must that hypothesis be, which neglects, as inconsiderable, a force amounting to more than twenty times the weight of the moving body?" We now proceed to state the postulates which contain the principles of the modern art of gunnery as found on the parabolic hypothesis. They are as follow:—

"1. If the resistance of the air be so small that the motion of a projected body is in the curve of a parabola, then the axis of that parabola will be perpendicular to the horizon, and consequently the part of the curve in which the body ascends will be equal and similar to that in which it descends.

"2. If the parabola in which the body moves be terminated on a horizontal plane, then the vertex of the parabola will be equally distant from its two extremities.

"3. Also the moving body will fall on that horizontal plane in the same angle, and with the same velocity with which it was first projected.

"4. If a body be projected in different angles but with the same velocity, then its greatest horizontal range will be when it is projected in an angle of 45° with the horizon.

"5. If the velocity with which the body is projected be known, then this greatest horizontal range may be thus found. Compute, according to the common theory of gravity, what space the projected body ought to fall through to acquire the velocity with which it is projected; then twice that space will be the greatest horizontal range, or the horizontal range when the body is projected in an angle of 45° with the horizon.

"6. The horizontal ranges of a body, when projected with the same velocity at different angles, will be between themselves as the sines of twice the angle in which the line of projection is inclined to the horizon.

"7. If a body is projected in the same angle with the horizon, but with different velocities, the horizontal ranges will be in the duplicate proportion of those velocities."

These postulates, which contain the principles of the parabolic theory of gunnery, would, if applied without reference to the resistance of the air, lead to great errors in practice; "for it has been already shown, that a musket-ball of three-fourths of an inch in diameter, fired with half its weight of powder, from a piece 45 inches long, moves with a velocity of near 1700 feet in a second. Now, if this ball flew in the curve of a parabola, its horizontal range at 45° would be found by the fifth postulate to be about seventeen miles. But all the practical writers assure us that this range is really short of half a mile. Diego Ufano assigns to an arquebuss, four feet in length, and carrying a leaden ball of 1½ oz. weight (which is very near our dimensions), a horizontal range of 797 common paces, when it is elevated between 40 and 50 degrees, and charged with a quantity of fine powder equal in weight to the ball. Mersennus also tells us, that he found the horizontal range of an arquebuss at 45° to be less than 400 fathoms, or 800 yards; whence, as either of these ranges is short of half an English mile, it follows, that a musket-shot, when fired with a reasonable charge of powder at the elevation of 45°, flies not one thirty-fourth part of the distance it ought to do if it moved in a parabola. Nor is this great contraction of the horizontal range to be wondered at, when it is considered that the resistance of this bullet when it first issues from the piece amounts to 120 times its gravity, as has been here experimentally demonstrated: or in the case of an iron bullet of 24 lbs. weight which, fired from a piece of the common dimensions, with its greatest allotment of powder, has a velocity of 1650 feet in a second, as already shown, if the horizontal range of the shot at 45° be computed on the parabolic hypothesis by the fifth postulate, it will come out to be about sixteen miles, which is between five and six times its real quantity; for the practical writers all agree in making it less than three miles."

In a similar manner, Robins pointed out that even with very moderate velocities the path of flight materially differs from a parabola, and that the highest point of flight is much nearer the place where the projectile falls to the ground than to that from whence it was at first discharged,—the descending curve being shorter and more inclined to the horizon than the ascending, as may be seen even in the figures of Tartaglia, cuts 1, 2, 3, 4; but it is not, at the present day, necessary to urge farther that the parabolic theory, though the necessary basis of theoretic gunnery, cannot of itself be applied in practice except when the initial velocities are less than 200 or 300 feet per second, when the resistance of the air becomes comparatively very small.

Mr Robins also first pointed out the fact, that from certain deviating forces which act upon the ball, it does not pursue that simple curved path which would be the result of the combined action of gravity and of the ordinary resistance of the air, both of which forces, acting in a vertical plane, have no tendency to produce lateral deflection, or to cause the ball to pursue a path of double curvature, or, as he expresses it, "to move on the surface of a cylinder the axis of which is perpendicular to the horizon." Didion thus states the causes of deviation:—"They are," he says, "of two kinds, namely, those which act on the projectile whilst still in the bore of the gun, so as to modify its direction and initial velocity, and which also produce a movement of rotation, as first observed by Robins, which becomes the cause of other deviations in the projectile; and, secondly, those which act upon the projectile during the whole time of its flight. The first deflect the projectile from the direction of the axis of the gun in proportion to the distance; the others may be considered accelerating forces, variable as each discharge, and even during the flight of a projectile, being distinct from gravity, which is constant, and from the resistance of the air, which is tangential to the trajectory of the projectile,—these two latter forces producing by their action what may be called the normal trajectory. Amongst the causes of deviation, some act in a permanent manner and produce effects which may be anticipated beforehand."

Deviation from the ball striking against the interior of the bore.—Solid balls, as well as hollow projectiles made of cast-iron, have always a diameter somewhat less than that of the bore of the gun for which they are intended. In consequence of this, the elastic gases escaping above the ball, which rests on the lower surface of the bore, press it down, producing much friction and a rotatory motion in the ball, whilst the gases pressing it behind produce a movement of translation. This pressure in bronze guns soon produces a depression or hollow, and the ball in consequence rises at an angle a little more elevated than the axis of the piece; and should the gun be short enough, this would be the final direction of the ball on leaving the gun; but, in general, such is not the case, and the ball will strike the upper part of the bore and be deflected downwards, when the result will be a depression of the true line of direction; or should it rebound again, an elevation—an effect which must increase as the gun becomes more worn. This deviation would be one merely in a vertical direction, were there not other causes tending to combine a lateral deviation with it, such, for example, as irregularities in the form and density of the projectile, as well as differences in its position as respects the charge, by which it happens that the resultant of the action of the gases is not exactly in the vertical plane, and the direction of the ball on leaving the gun diverges a little from that plane. The vertical deviation, though not always, is generally in elevation. From French experiments, it appears that with guns this deviation on an average amounts to $0^\circ\ 3\frac{1}{2}'$, and in howitzers to $0^\circ\ 10\frac{1}{2}'$—one-quarter of the shots from guns having an elevation of more than $8\frac{1}{2}'$, and about one-quarter a depression below the axis of $1\frac{1}{2}'$; whilst in howitzers one-fourth of the shells were elevated more than $15\frac{1}{2}'$, and one-fourth $5\frac{1}{2}'$ above the axis—the remaining half, as also in the guns, falling between these extreme numbers. In a horizontal direction, half of the shots deviated from the vertical plane passing through the axis more than $4\frac{1}{2}'$, either to the right or left, the others diverging less.

Robins and Lombard both determined experimentally the fact of deviation; the latter by placing a board screen marked by a horizontal and vertical line, at a short distance from the gun, and the intersection of the lines corresponding to the axis prolonged—the deviations of the ball when piercing the screen being thus at once exhibited; and Robins—who may be considered the author of experimental gunnery—by paper screens, as well as by board targets. The arrangement of screens which Mr Robins deemed the best he thus describes :—

"The apparatus was as follows. Two screens were set up in the larger walk in the Charter-house garden; the first of them at 250 feet distance from the wall, which was to serve for a third screen; and the second 200 feet from the same wall. At 50 feet before the first screen, or at 300 feet from the wall, there was placed a large block weighing about 200 lbs. weight, and having, fixed into it, an iron bar with a socket at its extremity, in which the piece was to be laid. The piece itself was of a common length, and bored for an ounce ball. It was each time loaded with a ball of 17 to the pound, so that the windage was extremely small, and with a quarter of an ounce of good powder. The screens were made of the thinnest tissue paper; and the resistance they gave to the bullet (and consequently their probability of deflecting it) was so small, that a bullet lighting one time near the extremity of one of the screens, left a fine thin fragment of it towards the edge entire, which was so very weak that it was difficult to handle it without breaking. These things thus prepared, five shots were made with the piece rested in the notch above mentioned; and the horizontal distances between the first shot, which was taken as a standard, and the four succeeding ones, both on the first and second screen, and on the wall, measured in inches, were as follows :—

	First Screen.	Second Screen.	Wall.
1 to 2	1·75 R.	3·15 R.	16·7 R.
3	10 L.	15·6 L.	69·25 L.
4	1·25 L.	4·5 L.	15·0 L.
5	2·15 L.	5·1 L.	19·0 L.

"Here the letters R and L denote that the shot in question went either to the right or left of the first.

"If the position of the socket in which the piece was placed be supposed fixed, then the horizontal distances measured above on the first and second screen, and on the wall, ought to be in proportion to the distances of the first screen, the second screen, and the wall, from the socket. But by only looking over these numbers, it appears that none of them are in that proportion; the horizontal distance of the first and third, for instance, on the wall being above nine inches more than it should be by this analogy.

"If, without supposing the invariable position of the socket, we examine the comparative horizontal distances according to the third method described above, we shall in this case discover divarications still more extraordinary; for by the numbers set down it appears that the horizontal distances of the second and third shot on the two screens, and on the wall, are as under :—

First Screen.	Second Screen.	Wall.
11·75	18·75	83·95

Here, if, according to the rule given above, the distance on the first screen be taken from the distances on the other two, the remainder will be 7 and 72·2; and these numbers, if each shot kept to a vertical plane, ought to be in the proportion of 1 to 5; that being the proportion of the distances of the second screen, and of the wall, from the first: but the last number 72·2 exceeds what it ought to be by this analogy by 37·2; so that between them there is a deviation from the vertical plane of above 37 inches, and this too in a transit of little more than 80 yards.

"But farther, to show that these irregularities do not depend on any accidental circumstance of the balls fitting or not fitting the piece, there were five shots more made with the same quantity of powder as before, but with smaller bullets, which ran much looser in the piece. And the horizontal distances being measured in inches from the trace of the first bullet to each of the succeeding ones, the numbers were as under :—

	First Screen.	Second Screen.	Wall.
1 to 2	15·6 R.	31·1 R.	94·0 R.
3	6·4 L.	12·75 L.	23·0 L.
4	4·7 R.	8·5 R.	15·5 R.
5	12·6 R.	24·0 R.	63·5 R.

Here, again, on the supposed fixed position of the piece, the horizontal distance on the wall between the first and third will be found about 15 inches less than it should be if each kept to a vertical plane; and like irregularities, though smaller, occur in every other experiment. And if they are examined according to the third method set down above, and the horizontal distances of the third and fourth, for instance are compared, those on the first and second screen, and on the wall, appear to be thus :

First Screen.	Second Screen.	Wall.
11·1	21·25	38·5

"And if the horizontal distance on the first screen be taken from the other two, the remainders will be 10·15 and 27·4; where the least of them, instead of being five times the first, as it ought to be, is 23·35 short of it; so that here is a deviation of more than 23 inches.

"From all these experiments, the deflection in question seems to be incontestibly evinced. But to give some farther light to this subject, I took a barrel of the same bore with that hitherto used, and bent it at about three or four inches from its muzzle to the left, the bend making an angle of three or four degrees with the axis of the piece. This piece thus bent was fired with a loose ball, and the same quantity of powder hitherto used, the screens of the last experiment being still continued. It was natural to expect, that if this piece was pointed by the general direction of its axis, the ball would be canted to the left of that direction by the bend near its mouth. But as the bullet, in passing through that bent part, would, as I conceived, be forced to roll upon the right-hand side of the barrel, and thereby its left side would turn up against the air, and would increase the resistance on that side, I predicted to the company then present, that if the axis on which the bullet whirled did not shift its position after it was separated from the piece, then, notwithstanding the bend of the piece to the left, the bullet itself might be expected to incurvate towards the right; and this, upon trial, did most remarkably happen. For one of the bullets fired from this bent piece passed through the first screen about $1\frac{1}{2}$ inch distant from the trace of one of the shots fired from the straight piece in the last set of experiments. On the second screen, the traces of the same bullets were about 3 inches distant; the bullet from the crooked piece passing on both screens to the left of the other; but comparing the places of these bullets on the wall, it appeared that the bullet from the crooked piece, though it diverged from the track on the two screens, had now crossed that track, and was deflected considerably to the right of it; so that it was obvious, that though the bullet from the crooked piece might first be canted to the left, and had diverged from the track of the other bullet with which it was compared, yet by degrees it deviated again to the right, and a little beyond the second screen crossed that track from which it before diverged, and on the wall was deflected 14 inches, as I remember, on the contrary side.

By this arrangement of several parallel screens it became evident that the ball did not always pursue the simple direction of the deflection it had received on leaving the bore, but from a cause acting during the flight was again deflected, sometimes, as in the curious experiment of the bent barrel, in an opposite direction to that of the original deflection. With his usual acumen Mr Robins assigned this effect to its true cause.

"The reality of this doubly curvated track being thus demonstrated, it may perhaps be asked, What can be the cause of a motion so different from what has been hitherto supposed? And to this I answer, that the deflection in question must be owing to some power acting obliquely to the progressive motion of the body; which power can be no other than the resistance of the air. If it be further asked, how the resistance of the air can ever come to be oblique to the progressive motion of the body, I farther reply, that it may sometimes arise from inequalities in the resisted surface, but that its general cause is doubtless a whirling motion acquired by the bullet about its axis; for by this motion of rotation, combined with the progressive motion, each part of the bullet's surface will strike the air very differently from what it would do if there was no such whirl; and the obliquity of the action of the air arising from this cause will be greater, as the rotatory motion of the bullet is greater in proportion to its progressive one.

"This whirling motion undoubtedly arises from the friction of the bullet against the sides of the piece; and as the rotatory motion will in some part of its revolution conspire with the progressive one, and in another part be equally opposed to it, the resistance of the air on the fore part of the bullet will be hereby affected, and will be increased in that part where the whirling motion conspires with the progressive one, and diminished where it is opposed to it; and by this means the whole effort of the resistance, instead of being opposite to the direction of the body, will become oblique thereto, and will produce those effects already mentioned. If it was possible to predict the position of the axis round which the bullet should whirl, and if that axis was unchangeable during the whole flight of the bullet, then the aberration of the bullet by this oblique force would be in a given direction, and the incurvation produced thereby would regularly extend the same way from one end of its track to the other. For instance, if the axis of the whirl was perpendicular to the horizon, then the incurvation would be to the right or left. If that axis was horizontal, and perpendicular to the direction of the bullet, then the incurvation would be upwards or downwards. But as the first position of this axis is uncertain, and as it may perpetually shift in the course of the bullet's flight, the deviation of the bullet is not necessarily either in one certain direction, or tending to the same side in one part of its track more than it does in another, but more usually is continually changing the tendency of its deflection, as the axis round which it whirls must frequently shift its position to the progressive motion by many inevitable accidents.

"That a bullet generally acquires such a rotatory motion as here described, is, I think, demonstrable; however, to leave no room for doubt or dispute, I confirmed it, as well as some other parts of my theory, by the following experiments:—

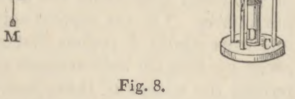

Fig. 8.

"I caused the machine to be made, represented fig. 8, BCDE is a brass barrel, moveable on its axis, and so adjusted by means of friction-wheels, not represented in the figure, as to have no friction worth attending to. The frame in which this barrel is fixed is so placed that its axis may be perpendicular to the horizon. The axis itself is continued above the upper plate of the frame, and has fastened on it a light hollow cone, AFG. From the lower part of this cone there is extended a long arm of wood, GH, which is very thin, and cut feather-edged. At its extremity there is a contrivance for fixing on the body whose resistance is to be investigated (as here the globe P); and to prevent the arm GH from swaying out of its horizontal position by the weight of the annexed body P, there is a brace, AH, of fine wire, fastened to the top of the cone which supports the end of the arm.

"Round the barrel BCDE there is wound a fine silk line, the turns of which appear in the figure; and after this line has taken a sufficient number of turns, it is conducted nearly in a horizontal direction to the pulley L, over which it is passed, and then a proper weight M is hung to its extremity. If this weight be left at liberty, it is obvious that it will descend by its own gravity, and will, by its descent, turn round the barrel BCDE, together with the arm GH, and the body P fastened to it. And whilst the resistance on the arm GH and on the body P is less than the weight M, that weight will accelerate its motion: and thereby the motion of GH and P will increase, and consequently their resistance will increase, till at last this resistance and the weight M become nearly equal to each other. The motion with which M descends, and with which P revolves, will not then sensibly differ from an equable one. Whence it is not difficult to conceive, that, by proper observations made with this machine, the resistance of the body P may be determined. The most natural method of proceeding in this investigation is as follows: Let the machine first have acquired its equable motion, which it will usually do in about five or six turns from the beginning; and then let it be observed, by counting a number of turns, what time is taken up by one revolution of the body P; then taking off the body P and the weight M, let it be examined what smaller weight will make the arm GH revolve in the same time as when P was fixed to it; this smaller weight being taken from M, the remainder is obviously equal in effort to the resistance of the revolving body P; and this remainder being reduced in the ratio of the length of the arm to the semidiameter of the barrel, will then become equal to the absolute quantity of the resistance. And as the time of one revolution is known, and consequently the velocity of the revolving body, there is hereby discovered the absolute quantity of the resistance to the given body P moving with a given degree of celerity.

"Here, to avoid all objections, I have generally chosen, when the body P was removed, to fix in its stead a thin piece of lead of the same weight, placed horizontally; so that the weight which was to turn round the arm GH, without the body P, did also carry round this piece of lead. But mathematicians will easily allow that there was no necessity for this precaution. The diameter of the barrel BCDE, and of the silk string wound round it, was 2·06 inches. The length of the arm GH, measured from the axis to the surface of the globe P, was 49·5 inches. The body P, the globe made use of, was of pasteboard; its surface very neatly coated with marbled paper. It was not much distant from the size of a 12-lb. shot, being in diameter 4·5 inches, so that the radius of the circle described by the centre of the globe was 51·75 inches. When this globe was fixed at the end of the arm, and a weight of half a pound was hung at the end of the string at M, it was examined how soon the motion of the descending weight M, and of the revolving body P, would become equable as to sense. With this view, three revolutions being suffered to elapse, it was found that the next 10 were performed in $27\frac{3}{4}^{s}$, 20 in less than 55^{s}, and 80 in $82\frac{1}{2}^{s}$; so that the first 10 were performed in $27\frac{3}{4}^{s}$, the second in $27\frac{1}{4}^{s}$, and the third in $27\frac{1}{2}^{s}$.

"These experiments sufficiently evince, that even with half a pound, the smallest weight made use of, the motion of the machine was sufficiently equable after the first three revolutions.

"The globe above mentioned being now fixed at the end of the arm, there was hung on at M a weight of $3\frac{1}{4}$ lbs.; and ten revolutions being suffered to elapse, the succeeding 20 were performed in $21\frac{1}{2}^{s}$. Then the globe being taken off, and a thin plate of lead, equal to it in weight, placed in its room; it was found, that instead of $3\frac{1}{4}$ lb. a weight of one pound would make it revolve in less time than it did before, performing now 20 revolutions after 10 were elapsed in the space of 19^{s}.

"Hence then it follows, that from the $3\frac{1}{4}$ lbs. first hung on, there is less than 1 lb. to be deducted for the resistance on the arm; and consequently the resistance on the globe itself is not less than the effort of $2\frac{1}{4}$ lbs. in the situation M: and it appearing from the former measures, that the radius of the barrel is nearly $\frac{1}{50}$th of the radius of the circle described by the centre of the globe, it follows, that the absolute resistance of the globe, when it revolves 20 times in $21\frac{1}{2}^{s}$ (about 25 feet in a second), is not less than the 50th part of two pounds and a quarter, or of 36 ounces; and this being considerably more than half an ounce, and the globe nearly the size of a 12-lb. shot, it irrefragably confirms a proposition I had formerly laid down from theory, that the resistance of the air to a 12-lbs. iron shot, moving with a velocity of 25 feet in a second, is not less than half an ounce.

"The rest of the experiments were made in order to confirm another proposition, namely, that the resistance of the air within certain limits is nearly in the duplicate proportion of the velocity of the resisted body. To investigate this point, there were successively hung on at M, weights in the proportion of the numbers 1, 4, 9, 16; and letting 10 revolutions first elapse, the following observations were made on the rest. With $\frac{1}{2}$ lb. the globe went 20 turns in $54\frac{1}{2}^s$, with 2 lbs. it went 20 turns in $27\frac{1}{4}^s$, with $4\frac{1}{2}$ lbs. it went 30 turns in $27\frac{1}{2}^s$, and with 8 lbs. it went 40 turns in $27\frac{1}{2}^s$. Hence it appears, that to resistances proportioned to the numbers 1, 4, 9, 16, there correspond velocities of the resisted body in the proportion of the numbers 1, 2, 3, 4: which proves, with great nicety, the proposition above mentioned.

"With regard to the rotatory motion, the first experiment was to evince, that the whirling motion of a ball combining with its progressive motion would produce such an oblique resistance and deflective power as already mentioned. For this purpose a wooden ball of $4\frac{1}{2}$ inches diameter was suspended by a double string about eight or nine feet long. Now, by turning round the ball, and twisting the double string, the ball when left to itself would have a revolving motion given it from the untwisting of the string again. And if, when the string was twisted, the ball was drawn to a considerable distance from the perpendicular, and there let go, it would at first, before it had acquired its revolving motion, vibrate steadily enough in the same vertical plane in which it first began to move; but when, by the untwisting of the string, it had acquired a sufficient degree of its whirling motion, it constantly deflected to the right or left of its first track, and sometimes proceeded so far as to have its direction at right angles to that in which it began its motion; and this deviation was not produced by the string itself, but appeared to be entirely owing to the resistance being greater on the one part of the leading surface of the globe than the other. For the deviation continued when the string was totally untwisted, and even during the time that the string, by the motion the globe had received, was twisting the contrary way. And it was always easy to predict, before the ball was let go, which way it would deflect, only by considering on which side the whirl would be combined with the progressive motion; for on that side always the deflective power acted, as the resistance was greater here than on the side where the whirl and progressive motion were opposed to one another."

Mr Robins also applied the whirling machine to the experimental illustration of the great difference of resistance offered by the air to the passage of bodies of equal surfaces, and even meeting the air at the same angle of obliquity, but of different forms; the difference being so great, "that though in one of them the resistance is less than that of a perpendicular surface meeting the same quantity of air, yet in another it shall be considerably greater."

"To make out this proposition, I made use of the machine already described; and having prepared a pasteboard pyramid, whose base was 4 inches square, and whose planes made angles of 45° with the plane of its base, and also a parallelogram 4 inches in breadth, and $5\frac{7}{8}$ in length, which was equal to the surface of the pyramid, the globe P was taken off from the machine, and the pyramid was first fixed on; and 2 lb. being hung at M, and the pyramid so fitted as to move with its vertex forwards, it performed twenty revolutions after the first ten were elapsed in 35^s. Then the pyramid being turned so that its base, which was a plane of 4 inches square, went foremost, it now performed twenty revolutions with the same weight in $38\frac{1}{4}^s$. After this, taking off the pyramid, and fixing on the parallelogram with its longer side perpendicular to the arm, and placing its surface in an angle of 45° with the horizon by a quadrant, the parallelogram, with the same weight, performed twenty revolutions in $43\frac{1}{2}^s$.

"Now here this parallelogram and the surface of the pyramid are equal to each other, and each of them met the air in an angle of 45°; and yet one of them made twenty revolutions in 35^s, whilst the other took up $43\frac{1}{2}^s$. And at the same time it appears that a flat surface, such as the base of a pyramid, which meets the same quantity of air perpendicularly, makes twenty revolutions in $38\frac{1}{4}^s$, which is the medium between the other two.

"But to give another and still more simple proof of this principle, there was taken a parallelogram 4 inches broad and $8\frac{1}{4}$th long. This being fixed at the end of the arm, with its long side perpendicular thereto, and being placed in an angle of 45° with the horizon, there was a weight hung on at M of $3\frac{1}{2}$ lbs. with which the parallelogram made twenty revolutions in $40\frac{3}{4}^s$. But after this, the position of the parallelogram was shifted, and it was placed with its shorter side perpendicular to the arm, though its surface was still inclined to an angle of 45° with the horizon; and now, instead of going slower, as might have been expected from the greater extent of part of its surface from the axis of the machine, it went round much faster; for in this last situation it made twenty revolutions in $35\frac{3}{4}^s$, so that there were 5^s difference in the time of twenty revolutions; and this from no other change of circumstance than as the larger or shorter side of the oblique plane was perpendicular to the line of its direction."

In the seventy-third volume of the *Philosophical Transactions*, several experiments on this subject, but upon a somewhat larger scale, as the arms of this modification of the whirling machine were about 6 feet long, are related by Lovell Edgeworth, Esq. They confirm the accuracy of Mr Robins' statements.

These are the principal experiments made by Mr Robins in confirmation of his theory, and which not only far exceed everything that had been previously done, but point out the only method by which the art of gunnery may be still further improved. It must be observed, however, that in this art it is impossible we should ever arrive at absolute perfection; that is, it can never be expected that a gunner, by any method of calculation whatever, can be enabled to point his guns in such a manner that the shot shall hit the mark if placed anywhere within its range. Aberration which can by no means be either foreseen or prevented, will take place from a great number of different causes. A variation in the density of the atmosphere, in the dampness of the powder, or in the figure of the shot, will cause variations in the range of the bullet, which cannot by any means be reduced to rules, and consequently must render the event of each shot very precarious. The resistance of the atmosphere simply considered, without any of those anomalies arising from its density at different times, is a problem which, notwithstanding the labours of Mr Robins and others, has not been completely solved; and, indeed, if we consider the matter in a physical light, we shall find that without some other data than those which are yet obtained, an exact solution of it is impossible. Professor Robinson, for example, the original writer of this article, proceeded at this point to investigate another difficult and obscure point connected with the resistance of the air to bodies passing with great velocity through it.

An objection has been made to the mathematical philosophy, to which in many cases it is most certainly liable, that it considers the *resistance* of matter more than its capacity of giving motion to other matter. Hence, if in any case matter acts both as a resisting and a moving power, and the mathematician overlooks its effort towards motion, founding his demonstrations only upon its property of resisting, these demonstrations will certainly be false. It is to an error of this kind that we are to attribute the great differences already noticed between the calculations of Sir Isaac Newton, with regard to the resisting force of fluids, and what actually takes place upon trial. These calculations were made upon the supposition that the fluid through which a body moved could do nothing else but resist it; yet it is certain that the air (the fluid with which we have to do at present) proves a source of *motion*, as well as resistance, to all bodies which move in it.

To understand this matter fully, let ABC represent a crooked tube made of any solid matter, and *a*, *b*, two pistons which exactly fill the cavity. If the space between these pistons be full of air, it is plain they cannot come into contact with each other, on account of the elasticity of the included air, but will remain at some certain distance, as represented in the figure. If the piston *b* be drawn up, the air which presses in the direction C*b* acts as a resisting power, and the piston will not be drawn up with such ease as if the whole was *in vacuo.* But though the column of air pressing in the direction C*b* acts as a resisting power on the piston *b*, the column pressing in the direction A*a* will act as a moving power upon the piston *a*. It is therefore plain, that if *b* be moved upwards till it comes to the place marked *d*, the other will descend to that marked *c*. Now, if we suppose the piston *a* to be removed, it is plain that when *b* is pulled upwards to *d*, the air descending through the leg A*a*CB will press on the under side of the piston *b*, as strongly as it would have done upon the upper side of the piston *a*, had it been present. Therefore, though the air passing down through the leg CB resists the motion of the piston *b* when drawn upwards, the air pressing down through the leg AB forwards it as much; and accordingly the piston *b* may be drawn up or pushed down at pleasure, and with very little trouble. But if the orifice at A be stopped, so that the air can only exert its resisting power on the piston *b*, it will require a considerable degree of strength to move the piston from *b* to *d*.

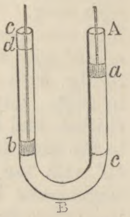

Fig. 10.

If now we suppose the tube to be entirely removed (which indeed answers no other purpose than to render the action of the air more evident), it is plain that if the piston be moved either up or down, or in any other direction we can imagine, the air will press as much upon the back part of it as it resists it on the fore part; and, consequently, a ball moving through the air with any degree of velocity, ought to be as much accelerated by the action of the air behind, as it is retarded by the action of that before. Here then it is natural to ask, if the air accelerates a moving body as much as it retards it, how comes it to make any resistance at all? Yet certain it is that this fluid does resist, and that very considerably. To this it may be answered, that the air is always kept in some certain state or constitution by another power which rules all its motions, and it is this power undoubtedly which gives the resistance. It is not to our purpose at present to inquire what that power is, but we see that the air is often in very different states; one day, for instance, its parts are violently agitated by a storm, and another perhaps they are comparatively at rest in a calm. In the first case, nobody hesitates to own that the storm is occasioned by some cause or other, which violently resists any other power that would prevent the agitation of the air. In a calm the case is the same; for it would require the same exertion of power to excite a tempest in a calm day as to allay a tempest in a stormy one. Now it is evident that all projectiles, by their motion, agitate the atmosphere in an unnatural manner, and consequently are resisted by that power, whatever it is, which tends to restore the equilibrium, or bring back the atmosphere to its former state.

If no other power besides that above mentioned acted upon projectiles, it is probable that all resistance to their motion would be in the duplicate proportion of their velocities; and accordingly, as long as their velocity is small, we find that generally it is so. But when the velocity comes to be exceedingly great, other sources of resistance arise. One of these is a subtraction of part of the moving power, which, though not properly a *resistance*, or opposing another power to it, is an equivalent thereto. This subtraction arises from the following cause:—The air, as we have already observed, presses upon the hinder part of the moving body by its gravity, as much as it resists the forepart of it by the same property. Nevertheless the velocity with which the air presses upon any body by means of its gravity is limited; and it is possible that a body may change its place with so great velocity that the air has not time to rush in upon the back part of it in order to assist its progressive motion. When this happens to be the case, there is in the first place a deficiency of the moving power equivalent to fifteen pounds on every square inch of surface, at the same time that there is a positive resistance of as much more on the fore part, owing to the gravity of the atmosphere, which must be overcome before the body can move forward.

This deficiency of moving power, and increase of resistance, do not only take place when the body moves with a very great degree of velocity, but in all motions whatsoever. It is not in all cases perceptible, because the velocity with which the body moves frequently bears but a very small proportion to the velocity with which the air presses in behind it. Thus, supposing the velocity with which the air rushes into a vacuum to be 1200 feet in a second, if a body moves with a velocity of 40 or 50 feet in a second, the force with which the air presses on the back part is but $\frac{1}{25}$th at the utmost less than that which resists on the fore part of it, which will not be perceptible; but if, as in the case of bullets, the velocity of the projectile comes to have a considerable proportion to the velocity wherewith the air rushes in behind it, then a very perceptible and otherwise unaccountable resistance is observed, as we have seen in the experiments already related by Mr Robins. Thus, if the air presses in with a velocity of 1200 feet in a second, and if the body changes its place with a velocity of 600 feet in the same time, there is a resistance of fifteen pounds on the fore part, and a pressure of only $7\frac{1}{2}$ on the back part. The resistance therefore not only overcomes the moving power of the air by $7\frac{1}{2}$ pounds, but there is a deficiency of other $7\frac{1}{2}$ pounds owing to the want of half the pressure of the atmosphere on the back part, and thus the whole loss of the moving power is equivalent to 15 pounds; and hence the exceeding great increase of resistance observed by Mr Robins beyond what it ought to be according to the common computations. The velocity with which the air rushes into a vacuum is therefore a desideratum in gunnery. Mr Robins supposes that it is the same with the velocity of sound; and that when a bullet moves with a velocity greater than that of 1200 feet in a second, it leaves a perfect vacuum behind it. Hence he accounts for the great increase of resistance to bullets moving with such velocities; but as he does not take notice of the loss of the air's moving power, the anomalies of all lesser velocities are inexplicable on his principles. Nay, he even tells us that Sir Isaac Newton's rule for computing resistances may be applied in all velocities less than 1100 or 1200 feet in a second, though this is expressly contradicted by his own experiments already mentioned.

Though for these reasons it is evident how great difficulties must occur in attempting to calculate the resistance of the air to military projectiles, we have not yet even discovered all the sources of resistance to these bodies when moving with immense velocities. Another power by which they are opposed, and which at last becomes greater than any of those hitherto mentioned, is the air's elasticity. This, however, will not begin to show itself in the way of resistance till the velocity of the moving body becomes considerably greater than that by which the air presses into a vacuum. Having therefore first ascertained this velocity, which we shall suppose to be 1200 feet in a second, it is plain that if a body moves with a velocity of 1800 feet in a second, it must compress the air before it; because the fluid has neither time to expand itself in order to fill the vacuum left behind the moving body, nor to rush in by its gravity. This compression it will resist by its elastic power, which thus becomes a new source of resistance, increasing, without any limit, in proportion to the velocity of the moving body. If now we suppose the moving body to set out with a velocity of 2400 feet in a second, it is plain that there is not only a vacuum left behind the body, but the air before it is compressed into half its natural space. The loss of motion in the projectile therefore is now very considerable. It first loses 15 pounds on every square inch of surface on account of the deficiency of the moving power of the air behind it, then it loses 15 pounds more on account of the resistance of the air before it; again, it loses 15 pounds on account of the elasticity of the compressed air; and lastly, it loses another 15 pounds on account of the vacuum behind, which takes off the weight of the atmosphere, that would have been equivalent to one-half of the elasticity of the air before it. The whole resistance therefore upon every square inch of surface moving with this velocity is 60 pounds, besides that which arises from the power tending to preserve the general state of the atmosphere, and which increases in the duplicate proportion of the velocity, as already mentioned. If the body is supposed to move with a velocity of 4800 feet in a second, the resistance from the elasticity of the air will then be quadrupled, or amount to 60 pounds on the square inch of surface, which, added to the other causes, will produce a resistance of 105 pounds upon the square inch; and thus the resistance from the elasticity of the air would go on continually increasing, till at last the motion of the projectile would be as effectually stopped as if it were fired against a wall. This obstacle, therefore, we are to consider as really *insuperable* by any art whatsoever, and therefore it is not advisable to use larger charges of powder than what will project the shot with a velocity of 1200 feet in a second. To this velocity the elasticity of the air will not make great resistance, if indeed it makes any at all; for though Mr Robins has conjectured that air rushes into a vacuum with the velocity of sound, or between 1100 and 1200 feet in a second, yet we have no decisive proof of the truth of this supposition. At this velocity, indeed, according to Mr Robins, a very sudden increase of resistance takes place; but this is denied by Mr Glenie, in his *History of Gunnery* (p. 48, 50), who supposes that the resistance proceeds gradually; and, indeed, it seems to be pretty obvious that the resistance cannot very *suddenly* increase, if the velocity be only increased in a small degree. Yet it is certain that the swiftest motions with which cannon-balls can be projected are very soon reduced to the standard; for Mr Robins informs us, that "a 24-pound shot, when discharged with a velocity of 2000 feet in a second, will be reduced to that of 1200 feet in a second in a flight of little more than 500 yards."

In the seventy-first volume of the *Philosophical Transactions*, Count Rumford has proposed as new a method of determining the velocities of bullets, by measuring the force of the recoil of the piece. As in all cases action and reaction are supposed to be equal to one another, it appears that the momentum of a gun, or the force of its recoil backwards, must always be equivalent to the force of discharge in the opposite direction; that is, the velocity with which the gun recoils, multiplied into its weight, is equal to the velocity of the bullet multiplied into its weight; for every particle of matter, whether solid or fluid, that issues out of the mouth of a piece, must be impelled by the action of some power, which power must *react* with equal force against the bottom of the bore. Even the fine elastic invisible fluid which is generated from the powder in its inflammation cannot put itself in motion without at the same time reacting against the gun. Thus we see pieces, when they are fired with powder alone, recoil as well as when their charges are made to impel a weight of shot, though the recoil is not in the same degree in both cases. It is easy to determine the velocity of the recoil in any given case, by suspending the gun in an horizontal position by two pendulous rods, and measuring the arc of its ascent by means of a ribbon, as in the Ballistic Pendulum; and this will give the momentum of the gun, its weight being known, and consequently the momentum of its charge. But in order to determine the velocity of the bullet from the momentum of the recoil, it will be necessary to know how much the weight and velocity of the elastic fluid contribute towards it.

That part of the recoil which arises from the expansion of the fluid is always very nearly the same as stated by Robins, whether the powder is fired alone, or whether the charge is made to impel one or more bullets, as has been determined by a great variety of experiments. If, therefore, a gun, suspended according to the method prescribed, is fired with any given charge of powder, but without any bullet or wad, and the recoil is observed, and if the same piece is afterwards fired with the same quantity of powder, and a bullet of a known weight, the excess of the velocity of the recoil in the latter case, over that in the former, will be proportional to the velocity of the bullet; for the difference of these velocities, multiplied into the weight of the gun, will be equal to the weight of the bullet multiplied into its velocity. Thus, if W is put equal to the weight of the gun; U = the velocity of the bullet when fired with a given charge of powder without any bullet; V = the velocity of the recoil when the same charge is made to impel a bullet; B = the weight of the bullet, and v = its velocity; it will be $v = \frac{(V - U)\,W}{B}$.

To determine how far this theory agreed with practice, an experiment was made with a charge of 165 grains of powder, without any bullet, which produced a recoil of 5·5 inches; and in another, the recoil was 5·6 inches, the mean of which is 5·55 inches, answering to a velocity of 1·1358 feet in a second. In five experiments with the same charge of powder, and a bullet weighing 580 grains, the mean was 14·6 inches; and the velocity of the recoil answering to the length just mentioned, is 2·9880 feet in a second; consequently V − U, or 2·9880 − 1·1358, is equal to 1·8522 feet in a second. But as the velocities of recoil are known to be as the chords of the arcs through which the barrel ascends, it is not necessary, in order to determine the velocity of the bullet, to compute the velocities V and U; but the quantity V − U, or the difference of the velocities of the recoil when the given charge is fired with and without a bullet, may be computed from the value of the difference of the chords by one operation. Thus the velocity answering to the chord 9·05 is that of 1·8522 feet in a second, which is just equal to V − U, as was before found.

In this experiment the weight of the barrel with its carriage was just $47\frac{1}{4}$ lbs., to which $\frac{3}{4}$ths of a pound were to be added on account of the weight of the rods by which it was suspended; thus making W = 48 lbs., or 336,000 grains. The weight of the bullet was 580 grains; whence B is to W as 580 to 336,000—that is, as 1 to 579·31 very nearly. The value of V − U, answering to the experiments before mentioned, was found to be 1·8522; consequently the velocity of the bullet = v was 1·8522 × 579·31 = 1073 feet, which differs only by 10 from 1083, the velocity found by the pendulum.

The velocities of the bullets may be found from the recoil by a still more simple method. For the velocities of the recoil being as the chords measured upon the ribbon, if c is put equal to the chord of the recoil expressed in English inches, when the piece is fired with powder only, and C = the chord when the same piece is charged with a bullet; then C − c will be as V − U; and consequently as $\frac{(V - U)\,W}{B}$, which measures the velocity of the bullet, the ratio of W to B remaining the same. If, therefore, we suppose a case in which C − c is equal to one inch, and the velocity of the bullet is computed from that chord, the velocity in any other case, wherein $C - c$ is greater or less than one inch, will be found by multiplying the difference of the chords C and c by the velocity answering to the difference of one inch. The length of the parallel rods by which the piece was suspended being 64 inches, the velocity of the recoil, $= C - c = 1$ inch measured upon the ribbon, is 0·204655 parts of a foot in one second, which in this case is also the value of $V - U$; the velocity of the bullet, or v, is therefore 0·204655 × 579·31 = 118·55 feet in a second. Hence the velocity of the bullet may in all cases be found by multiplying the difference of the chords C and c by 118·55, the weight of the barrel, the length of the rods by which it is suspended, and the weight of the bullet, remaining the same; and this whatever the charge of powder made use of may be, and however it may differ in strength and goodness.

The exactness of this second method will appear from the following experiments. On firing the piece with 145 grains of powder and a bullet, the mean of three sets of experiments was 13·25, 13·15, and 13·2; and with the same charge of powder without a bullet, the recoil was 4·5, 4·3, or 4·4. $C - c$, therefore, was 13·2 − 4·4 = 8·8 inches; and the velocity of the bullets, = 8·8 × 118·35 = 1045 feet in a second; the velocities by the pendulum coming out 1040 feet in the same space of time.

In the far greater number of experiments to determine the comparative accuracy of the two methods, a surprising agreement was found between the last-mentioned one and that by the pendulum; but in some few the differences were very remarkable. Thus, in two where the recoil was 12·92 and 13·28, the velocity, by computation from the chords, is 1030 feet per second; but in computing by the pendulum it amounted only to 900; in these, however, some inaccuracy was suspected in the experiment with the pendulum, and the computation from the recoil was most to be depended upon. In another experiment, the velocity by the recoil exceeded that by the pendulum by no less than 346 feet; the former showing 2109, and the latter only 1763 feet in a second.

These differences Count Rumford partly ascribed to the possibility of error in measuring the arc of ascent of the pendulum in his experiments, as the bullet was very light, consisting of a leaden casing over a plaster of Paris nucleus, and the movement of the pendulum very small in consequence; an error, therefore, of $\frac{1}{10}$th of an inch, if made in one of the experiments, being sufficient to account for 120 feet in a second of the difference in the velocity. The resistance also of the air in the passage of the ball from the barrel to the pendulum, distant 12 feet, was another supposed cause of the difference, as Count Rumford assumed, that in this passage, performed in the $\frac{1}{192}$d part of a second, the ball lost 335 feet of its velocity, and therefore struck the pendulum with a corresponding diminished force; but even after allowing for these causes of irregularity between the results of the two methods, he still found large differences, and was led to discover and admit that they were the consequence of the fracture of his balls by the concussion of firing. Indeed, Count Rumford afterwards observes,—

> "As allowance has been made for the resistance of the air in these cases, it may be expected that the same should be done in all other cases; but it will probably appear, upon inquiry, that the diminution of the velocities of the bullets on that account was so inconsiderable, that it might safely be neglected: thus, for instance, in the experiments with an ounce of powder, when the velocity of the bullet was more than 1750 feet in a second, the diminution turns out no more than 25 or 30 feet in a second, though we suppose the full resistance to have begun so near as two feet from the mouth of the piece; and in all cases where the velocity was less, the effect of the resistance was less in a much greater proportion; and even in this instance there is reason to think that the diminution of the velocity, as we have determined it, is too great; for the flame of gunpowder expands with such amazing rapidity, that it is scarcely to be supposed but that it follows the bullet, and continues to act upon it more than two feet, or even four feet, from the gun; and when the velocity of the bullet is less, its action upon it must be sensible at a still greater distance."

And hence it must be admitted that these experiments did not permit of a satisfactory comparison of the two methods of determining the recoil.

As Mr Robins considered that the whole of the powder of the charge is ignited before the ball *begins* to move, and that the gas proceeding from it is instantaneously produced, he came to the conclusion that the velocities of balls of the same size, though of different weights, would be reciprocally as the square roots of the weights; but Count Rumford proved that the ignition, even of the powder, was not instantaneous; and though Dr Hutton's experiments found this law to hold good, he considered this agreement to be the result of compensating circumstances, and states his own opinion that the correct law is nearly the reciprocal sub-triplicate ratio. Count Rumford also pointed out that Robins' estimate of the force of gunpowder—1000 to 1, as regards the pressure of the atmosphere—was too low, his own experiments making it 1308 to 1, an estimate still further raised by Hutton, as has been before stated, to 2000 to 1 or even 2230 to 1.

At this part of the subject it is necessary to point out the extraordinary importance of the labours of Robins, who was assuredly the pioneer of modern gunnery, and with whom commenced, as Sir Howard Douglas justly observes, a new era in the theory of gunnery. This success was due to the introduction of experimental proof; and simple as the means adopted were, they cannot be too highly prized for their efficiency. Didion quotes from the *Histoire de l'Academie des Sciences de Paris* (1707), a passage respecting the younger Cassini, which shows that he had adopted before Robins a practical application of the principle of "measuring the velocity of a projectile by that which it impresses upon a larger mass against, or into, which it is fired"—though with the object rather of testing the influence of the wad and of the disposition of the charge, than of measuring the velocity. Cassini's machine is described as a piece of wood armed at one end by a thick plate of cast-iron which was to resist the balls fired against it from the same musket, always placed at the same distance. The piece of wood was moveable so as to yield more or less to the shock, the extent of movement being marked or measured by the machine.

This simple plan was better fitted for measuring comparative than absolute results, and can scarcely, as suggested by Didion, have influenced Robins in his invention of the ballistic pendulum, first used in 1740, and the object of which was to measure the velocity of musket balls and the resistance of the air. To enlarge the sphere of inquiry, Dr Hutton, professor of mathematics at the Royal Military Academy, was subsequently authorized by the Master-General of the Ordnance to carry on several series of experiments, from 1775 to 1791, conjointly with Major (afterwards Sir Thomas) Blomefield, with a pendulum formed of pieces of wood clamped by iron, and weighing first 657 lbs. and then 2300 lbs., being intended to receive balls of 1 lb., 3 lbs., and 6 lbs. weight; and under the same authority, other series were undertaken in 1811, and from 1815 to 1818, the latter being entrusted to Dr Gregory, who had become professor of mathematics, and was associated with General Miller and Colonel Griffith—the weight of the pendulum being 7000 lbs., and the ball fired against it 12 lbs. These experiments deserve especial notice, not merely from their great importance, as determining essential elements in gunnery, but also from the evidence they afford of the active scientific spirit of some of the artillery officers of those days, and the example they set before the officers of the present. Nor were these experiments allowed to be carried on without turning them to account as a means of instruction—Dr Hutton carrying with him to the practice-ground his students of the first class of the gentlemen cadets. His words are—"On this occasion I took out with me, and employed the first class of gentlemen cadets belonging to the Royal Military Academy, namely, Messieurs Bartlett, Rowley, De Butts, Bryce, Wm. Fenwick, Pilkington, Edridge, and Watkins, who have gone through the science of fluxions, and have applied it to several important considerations in natural philosophy. These gentlemen I have voluntarily offered and undertaken to introduce to the practice of these interesting experiments, with the application of the theory of them, which they have before studied under my care. For though it be not my academy duty, I am desirous of doing this for their benefit, and as much as possible to assist the eager and diligent studies of so learned and amiable a class of young gentlemen, who, as well as the whole body of students now in the upper academy, form the best set of young men I ever knew in my life; nay, I did not think it even possible in any state of society in this country, for such a number of gentlemen to exist together in the constant daily habits of so much regularity and good manners, their behaviour being indeed perfectly exemplary; and I have no hesitation in predicting the great honour and future services which will doubtless be rendered to the state by such eminent instances of virtue and abilities;" and he added in a note, dated 1812, "At this distance of time, and long before, the world has had the satisfaction to find, that this prediction has been most amply and accurately fulfilled in every instance,"—a truth which will be admitted by all who still remember many of these names.

These remarkable words of a man who had raised himself, not only by talents of a very high order, but by unblemished character, to a position of great respectability and of high responsibility, deserve attention at this moment, when it is proposed to remodel the institution of which Dr Hutton was the distinguished professor of mathematics. By associating with him the gentlemen he has named, he took the first step towards the formation of a *Class of Application;* and this is really what should be done with the academy. Years ago a *practical* class was formed as supplementary to what is called the *theoretical* class; but such distinctions are not only erroneous but injurious, as theory and practice cannot be safely separated at any time, or at any period of a professional course. The gunner may, indeed, be taught much which is required from him practically; but the officer must be taught theoretically, and with him the subsequent training ought not to be merely practice, but the application of theory to practice. It is to men instructed at the Royal Military Academy in the highest branches of dynamics that we should look for the future improvement of our means of offensive and defensive warfare; and it is to be hoped, therefore, that the absurd distinctions between "theoretical" and "practical" classes will be abandoned; that the principle of "*application*" will be the characteristic of the reformed academy or college; and that its professors will be again associated with the officers of artillery in carrying on further experiments for the improvement both of the science and of the art of gunnery.

It has been already stated that Benjamin Thomson, Esq. (afterwards Count Rumford), furnished a paper to the Royal Society in 1781 containing various experiments made partly for the determination of the most advantageous situation for the vent in fire-arms, and partly to measure the initial velocity of bullets when discharged from them. In these experiments he merely employed, as Robins had done, a musket barrel; but in determining the velocity he used the recoil of the barrel itself, as well as the motion of the pendulum against which the ball was impelled. The former method Mr Thomson called "a new method;" but it had been previously pointed out by Robins, who also appears to have suggested the idea of applying it in the "eprouvette," for testing the comparative force of different samples of gunpowder, again proposed by Thompson, and subsequently so beautifully carried into effect by Hutton, who, in 1783, commenced his experiments with five brass one-pounders, cast expressly for the purpose, suspending the guns by a framework, and by additional weights, bringing them all up, including the weight of the suspending frame, to one weight —917 lbs. The weight of the ballistic pendulum was 559 lbs., and distance between the gun and ballistic pendulums was 35½ feet, the axis of the gun being point-blank, or horizontal. The first set of experiments was designed for the purpose of testing "the comparative strength of the different barrels of powder, by firing several charges of it, without balls or wads." So that in this case the gun pendulum became an eprouvette. It was found that the pendulum was considerably affected by the explosion of the powder, and in consequence a paper screen was afterwards interposed between the gun and ballistic pendulums. The recoils were found to be in a higher proportion than the charges of powder, as will be seen from the following statement of the results of four experiments:—

	Oz. of Powder.	Recoil in inches.	Proportions.	Second Prop.	Third do.
1.	2	4·5	2·40		
2.	4	10·8	2·29	·954	·99
3.	8	24·7	2·16	·944	
4.	16	53·3			

So that the first proportions, as ratios between the recoils, all exceed that of the charges as 1 to 2, approximating, however, to it with the increase of charge; and that the ratios between the successive ratios of recoil are nearly equal as shown in the 5th column. Dr Hutton then carried on several series of experiments for determining the velocities of the ball, both by the recoil of the gun and the vibration of the ballistic pendulum; and in his account of the experiments of 1786, he gives the following tabular view of the results, the velocities being given in feet per second:—

Comparison of the Velocities by the Gun and Pendulum.

Gun, No.	Charge, 2 oz.			Charge, 4 oz.		
	Velocity by		Dif.	Velocity by		Dif.
	Gun.	Pendulum.		Gun.	Pendulum.	
1	830	780	50	1135	1100	35
2	863	835	28	1203	1180	23
3	919	920	– 1	1294	1300	– 6
4	929	970	– 41	1317	1370	– 53
Gun, No.	Charge, 8 oz.			Charge, 16 oz.		
1	1445	1430	15	1345	1377	– 32
2	1521	1580	– 59	1485	1656	–171
3	1631	1790	–159	1680	1998	–318
4	1669	1940	– 271	1730	2106	–376

So that it appears that here, also, as in the experiments of Count Rumford, the recoil by the gun gave frequently a result very much in deficit of that given by the pendulum. The guns were those previously mentioned, all of the same calibre but of different lengths, the balls weighing a little more than 1 lb., and being all reduced by calculation, as regards the results, to a uniform size.

Dr Hutton concluded, from these results, that the velocities, determined from the two different ways, do not agree together, and that the method of determining the velocity of the ball from the recoil of the gun is not generally true; and, consequently, that the effect of the inflamed gunpowder on the recoil of the gun is not exactly the same when it is fired without a ball as when it is fired with a ball. The difference also does not appear to be regular, neither in different guns with the same charge, nor with different charges with the same gun. That with small charges the velocity by the gun is greatest; that the velocity by the pendulum continues to gain upon that by the recoil as the charges increase, and ultimately exceeds it more and more, as the charge of powder is increased.

Experiments in 1788 and 1789 were made with brass 3-pounders—one short and the other very long—so as to observe the effect both of length of gun and of weight of powder; the charges being 4 oz. and 16 oz. The weight of the pendulum was 1426 lbs. Amongst other results it was ascertained, that firing with 16 oz. of powder, or $\frac{1}{3}$ the weight of the ball, the long gun gave an initial velocity to its ball of 584 feet per second, and the short gun a velocity of 1371 feet per second; so that the velocity by the long gun exceeds that by the short by between the 6th and 7th part of the latter; the lengths of the guns being 40 inches and $69\frac{1}{4}$ inches.

In 1789 experiments were also made with a long 6-pounder, and in 1791 these were resumed with a new pendulum weighing 1630 lbs.; the weight of the gun being 1370 lbs., and the weight of the gun with its framework for suspension 1618 lbs. Afterwards a medium 6-pounder and a light 6-pounder were also used with successive pendulums weighing 1861 lbs. and 2119 lbs.; so that it may be said, without hesitation, that Dr Hutton's general experiments were by far the most important which had ever been made.

The velocities of the ball as discharged by the long gun, after some slight corrections made with a view of reducing the numbers to something like a regular series, but not such as to materially affect their absolute values, are as follows :—

Distance between gun and pendulum.	Dif.	Charge, 3 lbs.		Charge, 2 lbs.		Charge, $1\frac{1}{2}$ lb.		Charge, 1 lb.	
		Velocity.	Dif.	Velocity.	Dif.	Velocity.	Dif.	Velocity.	Dif.
30	85	1813	65	1676	58	1506	52	1306	47
115	85	1748	62	1618	56	1454	50	1259	45
200	85	1686	59	1562	54	1404	48	1214	43
285		1627		1508		1356		1171	

A table which shows that, with equal increments in the distance from the pendulum, there is a gradual diminution in the loss of velocity corresponding to the mean velocity at the middle of that increment; thus, when the mean velocity is 1780, the loss of velocity per second is 65 feet; when 1656, 59; when 1590, 56; when 1480, 52; when 1380, 48; when 1282, 47; when 1190, 43,—all agreeing very well in the corresponding decrease of the effect of the resistance of the air on the velocity of the ball, except the two means 1380 and 1282, which are too near each other in their results.

The velocities gained by the ball fired from the medium 6-pounder, at 30 feet distance, were—for 2 lbs. of powder, 1585 feet; $1\frac{1}{2}$ lb., 1460; 1 lb., 1260; $\frac{1}{2}$ lb., 877. The velocities gained by the ball fired from the light 6-pounder, at 30 feet distance, were—for 3 lbs. of powder, 1624; 2 lbs., 1558; $1\frac{1}{2}$ lb., 1440; and, by calculation, Dr Hutton determined that a 6-lb. ball, moving with the velocity of 1200 feet per second, was resisted by a force equal to 115 lbs.; and when moving with a velocity of 1600 feet per second, with a force of nearly 222 lbs.,—results of great importance.

In France, similar experiments had been made at Metz, in 1839 and 1840, with the French 24, 12, and 8-pounders, and their howitzer of 22 c., or $8\frac{1}{2}$ inches. For these experiments, however, a considerable change had been effected in the instrument, as shown in fig. 10. Instead of a mass of wood, requiring frequent renewal, as in the English pendulum, a more permanent receiver was substituted, which, being filled with some material moderately penetrable, can be used without limitation.

The ballistic pendulum, then (fig. 10), consists of a conical vase of cast-iron, A, called the ballistic receiver, and suspended by four rods, B B, B′ B′, to an axis, C, 16 feet above it. The two rods, B B, embrace the front, and B′ B′ the rear of the receiver; and further, the two rods on the same side of the receiver approximate together at the top, so as to be connected with the one end of the axis, whilst the two on the other side are connected with the other end. The rods are bound together by four cross pieces, D, D,′ E, E′, and by three ties, F, F′, C, which render the whole system rigid. The ties, which unite together the rods below, are seen in H, K, and K′, the whole being secured by a screw-bolt, L, below, and another, M, above; the bolt, L, carrying a moveable weight formed of discs of lead, N, and kept in position on the bolt by the springs, O. This weight, the position and magnitude of which can be changed, serves either to depress (if necessary) the centres of gravity and oscillation of the receiver, and to render its axis horizontal. The axis, C, is of iron, and is shaped at its extremities, P, into knife-edges, slightly curved, and resting on the steel plates or bearers, Q, Q, the upper surface of which is formed into two planes, meeting in a curve of double the radius of that which forms the bearing of the knife-edges. The bearers, Q, Q, rest on cast-iron plates, R, R, which are firmly fixed upon two piles or piers of masonry. The receiver, SSS, is shaped within as a truncated cone, the bottom of which

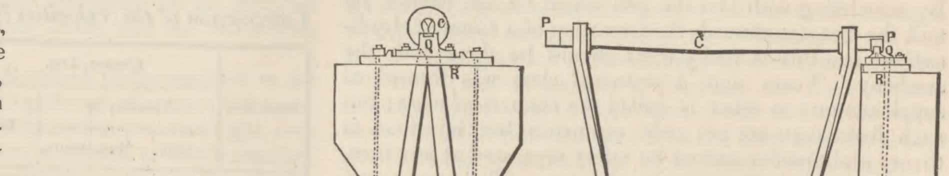

Fig. 10.

is rounded off, and it is sufficiently long to prevent the projectile from passing entirely through the sand with which it is filled; it is formed of cast-iron, and strongly bound by hoops of forged iron. The front is covered with a thin sheet of lead to prevent the sand from being shaken out, and this sheet is marked by a horizontal and by a vertical line, the intersection corresponding to its axis; and the actual position of the shot when entering the receiver can be therefore readily determined by reference to these lines.

It will be readily supposed that this ingenious contrivance would not be effectual at the long distances required for firing to determine the resistance of the air, as the ball would frequently strike the exterior rim of the receiver instead of penetrating within it. On account of this practical defect another pendulum, fig. 11, has been contrived.

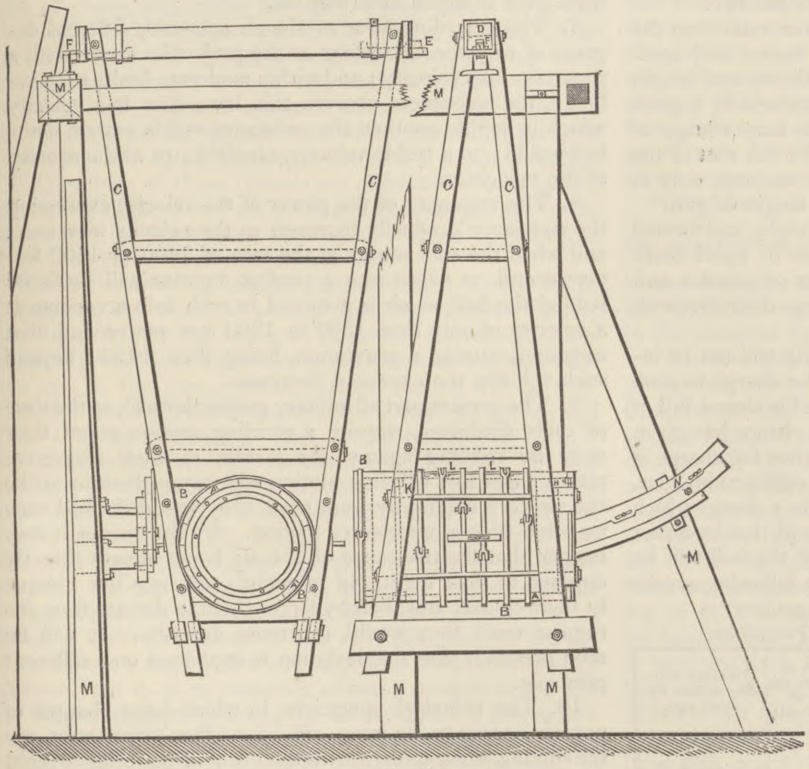

Fig. 11.

This is composed of an external hollow wooden cylinder, 7½ feet long and 5 feet in external diameter, strongly bound by iron hoops, B, and connected by four wooden suspending rods with a wooden axis, D, in which are firmly fixed knife-edges, F. The receiver, AA, within is made of double plate-iron, and its interior diameter is 4 feet 4½ inches. The bottom, H, is closed solidly with wood; and in front, at K, is an advanced bottom formed of ¾th-inch board, the interval between the two, a length of 4¾ feet, being filled with sand, introduced by openings from above, subsequently closed by the iron doors, L, L. The whole receiver, when filled with sand, weighed 14,000 lbs., the sand itself weighing more than the one half. Sir H. Douglas mentions that the Chevalier d'Antoni carried on similar experiments at Turin in 1761, though with a different kind of machine; and that Major Mordecai, of the United States artillery, made experiments, under the authority of the government of that country, with an apparatus constructed on the French principle—the suspended gun being either a 24 or a 32-pounder, weighing, with the suspending apparatus, 10,500 lbs., and the receiver pendulum 9358 lbs.; so that it may be now said with some degree of vexation, though with truth, that the only school of artillery without the means of carrying on ballistic experiments, namely, the gun pendulum and the receiver pendulum, is that of England, the country of Robins and Hutton. It is surely time that we should awaken from this sleep, and cease to be satisfied with the results obtained, or the honours acquired by these illustrious men.

In respect to velocities below 300 feet per second, it was found difficult to test them by the ordinary form of ballistic pendulum, as the balls dropped from it without penetrating. This defect might have been avoided by arrangements similar to those of the receiver form of pendulum; but in the meantime Robins' whirling machine was applied to this object. Robins' own experiments have already been alluded to. In 1763 were published experiments made in France by Borda, with a machine similar in principle to that of Robins, though differently arranged (fig. 12). In this, a horizontal axis, AB, carries a small cylinder, round which winds a cord, at the extremity of which is a weight, E, which gives motion to the fly. A thin rod, PGK, wedge-shaped, forms the two arms of the fly—two equal surfaces, P and K, being adapted to their extremities, the centre of which is about 4 feet from the axis of rotation. On the string two marks, distinctly visible, are fixed, and by the aid of a half-seconds pendulum the interval of time between the passage of these marks was measured to a ¼th of a second; and the number of turns corresponding to this length on the cord being known, it was easy to compute the velocity of rotation, and, consequently, the absolute velocity of the centres of the resisting surfaces themselves—care having been taken that the velocity had become uniform at the fifth turn, or just at the passage of the first mark—and the moving weight, therefore, exactly counterbalancing the resistance of the air during the 22 turns corresponding to the interval between the two marks; the proportions between the radii of the cylinder and of the fly being taken into account. By employing different weights, the resistances corresponding to different velocities are obtained.

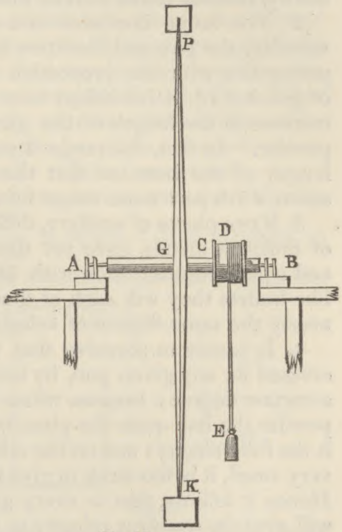

Fig. 12.

Hutton made very extensive experiments with the apparatus of Robins; and in like manner M. Thibault, of the French Marine, has made experiments (1826) with one similar to that of Borda.

II.—APPLIED GUNNERY.

A consideration of what has been said respecting the experiments of Robins, Hutton, and many others, must have been sufficient to convince every one that the application of the theory of gunnery, or of any theory of the motion of bodies in a fluid, to the practical purposes of war, so essentially depends on the knowledge of elements very difficult of determination—such as the initial expansive force of the gases produced by the combustion of gunpowder, and the complicated resisting force of the air—that it has been found absolutely necessary to determine these elements, or the proximate results depending on them, such as the velocity of the projectile, by direct experiments. The following deductions have been made from experiments, and may therefore be considered as principles of the science:—

1. Two pieces of the same bore, but of different lengths, being fired with the same charge of powder, the longer will impel the bullet with a greater velocity than the shorter; but the increase in velocity is very small in comparison to the increase in length—the velocities being in a ratio somewhat less than that of the square roots of the length of the bore, but greater than that of the cube roots of the same, nearly, indeed, in the middle ratio between the two.

2. The range increases in a much lower ratio than the velocity, the gun and elevation being the same; and comparing this with the proportion of the velocity and length of gun in (1.), it is evident how little is gained by a great increase in the length of the gun with the same charge of powder. In fact, the range is nearly as the 5th root of the length of the bore, so that the increase amounts only to about a 7th part more range for a double length of gun.

3. If two pieces of artillery, different in weight, and formed of different metals, have yet their cylinders of equal bores and equal lengths; then with like charges of powder and like bullets they will each of them discharge their shot with nearly the same degree of velocity.

4. It is easy to perceive that the velocity will not be increased for any given gun, by increasing the charge beyond a certain degree; because when the barrel is almost full of powder the ball quits the piece before the charge has given it the full velocity; and on the other hand when the charge is very small, it is too weak to give the ball a sufficient impulse. Hence it follows, that in every gun there is a charge which will give the greatest velocity to the ball, and that by either increasing or diminishing it, the motion of the ball will be diminished. Dr Hutton further gives the following results of his theoretical and experimental investigations:—

Table of Charges for the greater Velocities.

Length of bore in calibres.	Length of charge in calibres.	Proportion of length of bore to length of charge.	Weight of powder in 100 parts of weight of ball.	Greatest velocity of ball by each gun.
2	0·63	3·171	12	810
4	1·20	3·333	23	1122
6	1·72	3·488	33	1348
8	2·20	3·636	42	1529
10	2·64	3·788	50	1681
12	3·05	3·934	58	1813
14	3·43	4·082	65	1929
16	3·78	4·233	71	2033
18	4·11	4·380	78	2127
20	4·42	4·525	84	2213
22	4·71	4·671	90	2292
24	4·99	4·810	95	2366
26	5·25	4·952	100	2434
28	5·50	5·091	105	2498
30	5·73	5·235	109	2558
32	5·96	5·369	113	2614
34	6·17	5·510	117	2668
36	6·37	5·651	121	2719
38	6·56	5·793	125	2767
40	6·75	5·926	128	2813
42	6·93	6·061	132	2857
44	7·10	6·197	135	2899
46	7·27	6·328	138	2939
48	7·43	6·460	141	2978
50	7·58	6·596	143	3015
52	7·72	6·736	146	3051
54	7·86	6·870	149	3085
56	8·00	7·000	152	3118
58	8·13	7·134	155	3150
60	8·26	7·264	157	3181

Now, then, in the 32-pounder of 56 cwt., the bore of which is about 17 calibres in length, the charge would occupy somewhat less than $\frac{1}{4}$th of the length of the bore, and would weigh nearly $\frac{3}{4}$ths of the weight of the ball, the extreme velocity being about 2080 feet per second.

5. The resistance of the air acts upon projectiles in a twofold manner; for it opposes their motion, and thus continually diminishes their velocity; and diverts them from the regular track they would otherwise follow, under certain conditions of the form and motion of the projectiles, which will be hereafter discussed.

6. That action of the air by which it retards the motion of projectiles, though formerly neglected by writers on artillery, is yet, in many instances, of an immense force; and hence the motion of these resisted bodies is totally different from what it would otherwise be.

7. This retarding force of the air acts with different degrees of violence, according as the projectile moves with a greater or less velocity; and within moderate limits as to velocity, the resistances observe this law—that to a velocity which is double another, the resistance within certain limits is fourfold; to a treble velocity, ninefold; or as the squares of the velocities.

8. The exponent of the power of the velocity expressing the resistance gradually increases as the velocity increases; and when the shot moves at the rate of 1400 or 1500 feet per second, at which rate a perfect vacuum will be found behind the ball, as air is assumed to rush into a vacuum at a velocity of only from 1200 to 1300 feet per second, that exponent attains a maximum, being then 2·125; beyond such velocity the exponent decreases.

9. The greater part of military projectiles will, at the time of their discharge, acquire a whirling motion round their axis, by rubbing against the insides of their respective pieces; and this whirling motion will cause them to strike the air very differently from what they would do had they no other than a progressive motion. By this means it may happen that the resistance of the air is not always directly opposed to their flight, but frequently acts in a line oblique to their course, and thereby forces them to deviate from the regular track they would otherwise describe. It will be seen presently that the deviation is explained on a different principle.

10. The principal operations in which large charges of powder appear to be more efficacious than small ones, are the ruining of parapets, the dismounting of batteries covered by stout merlons, or battering in breach; for in all these cases, if the object be but little removed from the piece, every increase of velocity will increase the penetration of the bullet.

11. Whatever operations are to be performed by artillery, the least charges of powder with which they can be effected are always to be preferred.

12. Hence the proper charge of any piece of artillery is not always that allotment of powder which will communicate the greatest velocity to the bullet; nor is it to be determined by an invariable proportion of its weight to the weight of the ball; but, on the contrary, it is such a quantity of powder as will produce the fitting velocity for the purpose in hand; and, instead of bearing always a fixed ratio to the weight of the ball, it must be different according to the different business which is to be performed.

13. Robins, following out these rules, states that no field-piece ought at any time to be loaded with more than $\frac{1}{6}$th, or, at the utmost, $\frac{1}{5}$th of the weight of its bullet in powder, nor should the charge of any battering piece exceed $\frac{1}{3}$d of the weight of its bullet; but these proportions are not adhered to strictly in modern practice, *light* field-pieces being, however, fired with so small a charge as $\frac{1}{4}$th.

14. If balls have equal weights but different diameters, and move with equal velocities, the resistance varies nearly

with the surfaces or with the squares of the diameters, increasing a little above that proportion when the diameters are considerable. Hence, if the velocities are also different, the resistance is proportional to the surface and to the square of the velocity; or r representing the semi-diameter of the shot, and v the velocity, the resistance varies with $r^2 v^2$.

15. If balls have equal diameters and different weights or densities, the resistances vary directly as the squares of the velocities, and inversely as the weights; or, w representing the weight, the resistance varies with $\frac{v^2}{w}$.

Great irregularities in the motion of bullets are, as we have seen, owing to the whirling motion on their axis, acquired by the friction against the sides of the piece. The best method hitherto known of preventing these is by the use of pieces with *rifled barrels.* These pieces have the insides of their cylinders cut with a number of spiral channels; so that it is in reality a female screw, varying from the common screws only in this, that its threads or rifles are less deflected, and approach more to a right line; it being usual for the threads with which the rifled barrel is indented, to take little more than one turn in its whole length. The numbers of these threads are different in each barrel, according to the fire of the piece and the fancy of the workman; and in like manner the depth to which they are cut is not regulated by any invariable rule.

From the whirling motion communicated by the rifles, it happens, that when the piece is fired, the indented zone of the bullet follows the sweep of the rifles, and thereby, besides its progressive motion, acquires a circular motion round the axis of the piece; which circular motion will be continued to the bullet after its separation from the piece; and thus a bullet discharged from a rifle barrel will revolve round an axis coincident with the line of its flight. By this rotation on its axis, the aberration of the bullet, which proves so prejudicial to all operations in gunnery, is almost totally prevented. The reason of this may be easily understood from considering the slow motion of an arrow through the air. For example, if a bent arrow, with its wings not placed in some degree in a spiral position, so as to make it revolve round its axis as it flies through the air, were shot at a mark with a true direction, it would constantly deviate from it, in consequence of being pressed to one side by the convex part opposing the air obliquely. Let us now suppose this deflection in a flight of 100 yards to be equal to ten yards. Now if the same bent arrow were made to revolve round its axis once every two yards of its flight, its greatest deviation would take place when it had proceeded only one yard, or made half a revolution; since at the end of the next half revolution it would again return to the same direction it had at first; the convex side of the arrow having been once in opposite positions. In this manner it would proceed during the whole course of its flight, constantly returning to the true path at the end of every two yards; and when it reached the mark, the greatest deflection to either side that could happen would be equal to what it makes in proceeding one yard, equal to $\frac{1}{100}$th part of the former, or 3·6 inches—a very small deflection when compared with the former one. In the same manner, a cannon-ball which revolves not round its axis, deviates greatly from the true path, on account of the inequalities on its surface; which, although small, cause great deviations by reason of the resistance of the air, at the same time that the ball acquires a motion round its axis in some uncertain direction occasioned by the friction against its sides. But by the motion acquired from the rifles, the error is perpetually corrected in the manner just now described; and accordingly such pieces are much more to be depended on, and will do execution at a much greater distance than the other.

16. *Deviations.*—It has been shown that Robins pointed out the deviations which are occasioned in the course of projectiles by a rotation in them, produced by any accidental cause, on an axis not coincident with the line of flight; and in the last two paragraphs reference has been made to the artificial means adopted by rifling, or grooving, the bores of the barrel of muskets, to give to the projectile an initial rotatory movement round an axis coincident with the line of flight, and thereby to avoid such extraneous cause of deflection. Robins made many experiments with rifles, to show that the accuracy of fire at great distances thus obtained is their principal advantage, and that they have not an advantage over the unrifled barrel as regards either extent of range or penetrative power; the increased force supposed to have been gained by more completely shutting in, as it were, the elastic gases, and thus avoiding the loss by windage, being counterbalanced by the great friction of the ball in its passage through the bore. Robins also suggested the use of an ovoid, or egg-shaped ball; but in this respect the indications of Newton as to the form of the solid body which, in passing through a fluid, would experience less resistance than a body of equal magnitude and of any other form, have gradually led to the adoption of the modern elongated balls. Sir Howard Douglas has given a very clear view of the subject, and his remarks will be here quoted:—

"The body is a solid of revolution, and the differential equation is $y = c\,\frac{dz^4}{dy^3\,dx}$, in which c is a constant, y is any ordinate, and dx, dy, dz, are elementary portions, EF, ED, DF, respectively, in the sectional figure.

"The two ends A and B of the solid are both plane surfaces, as DF $= dz$ is greater than EF or ED—dx, dy, and therefore the numerator of the fraction must always be greater than the denominator, and y cannot become 0, or coincide with H. That the minimum of resistance should be obtained from an elongated shot of this, or any form approximating to it, it is necessary that the axis AB should always be kept in the direction of the trajectory, an object which is accomplished by producing a rotatory motion round that axis, the ball being discharged from a rifled bore. Were it not that such a rotation were produced, the axis would perpetually deviate from the direction of the path and even turn over."

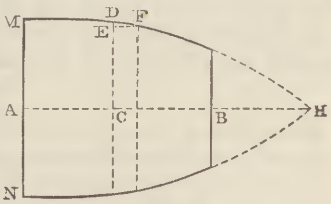

Fig. 13.

The advantages of this form of shot are, that when rotatory on their longitudinal axis, and moving with their smaller extremities in front, they experience less resistance from the air than spherical projectiles of the same diameter. To this form alone are to be referred the long range, with the great momentum and penetrating power of the projectiles for rifle muskets, which have been recently introduced into British and foreign military services. Sir Howard Douglas describes also the cylindro-conical and cylindro-conoidal balls used in the iron-rifled guns, invented in 1846 by Major Cavalli of the Sardinian artillery, and Baron Wahrendorff, a Swedish noble. The entire lengths of these projectiles were—of the cylindro-conical $16\frac{3}{4}$ inches, and of the cylindro-conoidal $14\frac{3}{4}$ inches, their greatest diameter being $6\frac{1}{2}$ inches. They were made to act upon the grooves of the bore by two projections, one on each side, making each an angle with the axis of the shot of 7° 8′. If hollow, the weight was about 62 lbs., and if solid about $101\frac{1}{2}$ lbs.,—the hollow projectiles being burst on the principle of a percussion shell. These guns are loaded at the breech. The difficulty of forming a convenient and efficient rifled cannon has indeed been so great, that it may be considered to remain as yet an unsolved problem in the ordinary way; but Mr Lancaster has adopted a different principle, and patented an ingenious invention for causing a shot to rotate on its axis throughout the range, by firing it from a cannon having an elliptical bore of small excentricity. The 68-pounder gun has been bored up to the elliptic section, and the shell, as shown in Plate II., fig. 18, adopted—the transverse section of the shell being elliptical. It is well known that several of Lancaster's guns were in operation during the last remarkable campaign, though no official account of the result of their practice has yet been published; but that at Shoebury-Ness is considered on the whole satisfactory, both as to extent of range and precision in firing, more especially at the longer ranges, since the 68-pounder, one of the best guns in the service, maintains an equality in short and medium ranges. The major axis of the ellipse of the bore does not continue parallel to one fixed line, but makes a revolution of about $\frac{1}{4}$th of the periphery in its length, and the elliptic shot, following necessarily the course of this helix, is caused to rotate on its long axis. Much precision is required in putting the ball into the gun, but this is attained by a very simple machine lately adopted by Mr Lancaster for the purpose, and which does away with any chance of mistake.

Turning again from these modes of correcting irregular rotation, by inducing a regular one in the direction of the line of the trajectory, to the consideration of the deviations produced by any irregular rotation, it may be first premised, that not only vertical but also lateral deflections must be the result of such rotations. Irregular rotations may be produced, as suggested by Robins, by a rolling motion in the bore; or this may be the result of unequal density in the different portions of the ball, causing the centres of gravity and of figure not to coincide. Thus, for example,

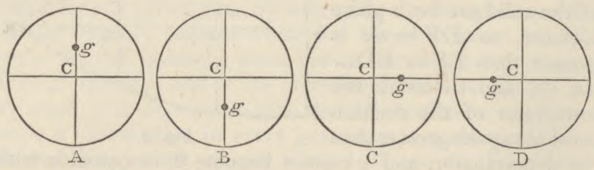

Fig. 14.

if the centre of gravity, g, be above the centre of figure, C, in A of the four circular sections, the resultant of the projecting forces will cause the front of the shot to turn from below upwards; if below, as in B, from above downwards; if to the right, as in C, from the left to the right; and if to the left, as in D, from the right to the left. In all these cases the deflection will be in the direction of the rotation, namely, it will be upwards in A, producing an increase of range, downwards in B, or diminishing the range, to the right in C, and to the left in D.

These theoretical deductions have been fully confirmed by experiments, both in England and France.

At the instance of Sir Howard Douglas, experiments were made both by the navy on board the "Excellent" gunnery ship, and by the ordnance at Shoebury Ness, with a view to ascertain not only the nature of these deflections, but also the practicability of making a useful application of the principle of eccentric projectiles as a means of increasing the range:—

Excellent, *July* 18, 1850.—With a 32-pounder gun of 56 cwt.—the quantity of metal removed from one side of the shot being 1 lb.

	Charge 8 lbs. Elevation 2° $7\frac{1}{2}'$.		Charge 10 lbs. Elevation 3° 30′.	
Position of centre of gravity with respect to centre of shot.	Range in yards.	Deflection in yards.	Rango in yards.	Deflection in yards.
On the right, ...	1032	6 right	1474	20 right
On the left,............	1163	7 left	1479	$24\frac{2}{3}$ left
Upwards, ...	1433	7 R. $3\frac{1}{2}$ L.	1991	20 R. 6 L.
Downwards, ...	980	5 R. 3 L.	1499	2 R. $6\frac{1}{2}$ L.
Inwards, ...	1150	$4\frac{1}{2}$ right	1608	$5\frac{1}{2}$ R.
Outwards, ...	1097	$4\frac{2}{3}$ right	1428	9 R.
Concentric, ...	1160	4 R. 3 L.	1624	1 R.

In these the deflections are also given in yards, being the mean of all the rounds under similar circumstances; hence, of course, where some were deflected to the right and others to the left, the mean of each set is given. It will be observed that with the lesser charge and elevation a difference of 453 yards is produced in the range by shifting the centre of gravity from above to below the centre of figure, and with the higher charge and elevation, a difference of 492 yards. The lateral deflections, however, are by no means so considerable, amounting in the one case to $6+7=13$ yards, and in the other to $20+24\frac{2}{3}=44\frac{2}{3}$ yards. With an 8 inch-gun, 9 feet long, and weighing 65 cwt., the quantity of metal removed from one side of the shot being 5 lbs. 5 oz., the difference between the ranges, according as the centre of gravity was placed above or below the centre of figure, was 189 yards when fired with a charge of 10 lbs., and elevation of 2° 30′, and 378 with the same charge and an elevation of 5°. With a 32-pounder, charge 8 lbs., and elevation 12°, 1 lb. of metal being removed from one side, the difference 938 yards; and with another 8-inch gun, the quantity of metal removed from one side being 3 lbs., the charge 10 lbs., and elevation 10°, the difference was 1132 yards. The experiments of Shoebury Ness were similar in their results,—the eccentric hollow shot in those of 1851 giving an increase of range, as compared with concentric shot, varying, according to the absolute range and elevation, from 145 yards in a range of 1700 yards, and an elevation of 4°, to 559 in a range of 2465 yards, and 8° of elevation; 621 in a range of 3184 yards, and 12° of elevation; 749 in a range of 3709 yards, and 16° of elevation; 939 in 4137 yards, and 20° of elevation; 706 in 4605 yards, and 24° of elevation; 916 in 4650 yards, and 28° of elevation; and 670 in 4866 yards, and 32° of elevation—the ranges stated being those of the concentric shot, and the range of the eccentric being obtained by adding to the other the differences here stated—the highest range being that of the eccentric shot with 28° of elevation, which amounted to 5566 yards, or about $3\frac{1}{6}$ miles. The lateral deflections in the long ranges were very great—the extreme to the left being 361 yards, and the extreme to the right 255 yards; but it is remarkable that some of the deflections of the concentric shot were quite equal, and some even exceeded those of the eccentric shot.

Captain Boxer, in his Treatise on Artillery, gives more copious details of the practice at Shoebury Ness, but the above extracts are sufficient for the present purpose. Similar experiments were made at Metz in 1839, with common and eccentric shells of 11 inches diameter, and the results are given by Didion in the following table:—

Nature of gun.	Weight of charge in lbs.	Weight of shell in lbs.	Range in Yards.		
			With common shell.	Eccentric centre of gravity.	
				Below.	Above.
...	...	$58\frac{3}{4}$	$774\frac{1}{3}$	...	...
Siege......	3 lb. 5 oz.	66	...	$566\frac{1}{2}$	1039
...	...	$61\frac{1}{2}$	...	$599\frac{1}{3}$	$1029\frac{1}{3}$
...	...	$58\frac{3}{4}$	$950\frac{1}{3}$	...	...
Coast.....	3 lb. 5 oz.	66	...	$778\frac{2}{3}$	1272
...	...	$61\frac{1}{2}$	...	$799\frac{1}{2}$	$1103\frac{1}{2}$
...	...	$58\frac{3}{4}$	$1279\frac{2}{3}$	...	...
Coast.....	6 lb. 10 oz.	66	...	$1172\frac{1}{3}$	1703
...	...	$61\frac{1}{2}$	...	$1221\frac{2}{3}$	1444

All these experiments lead to the same conclusions, that when applied in such cases as the above on accurate principles for the express purpose of obtaining an increase of range, the eccentric shot, and more especially shells, may be sometimes used with advantage, but that, as a general rule, the great practical difficulties of ensuring certainty in their use in the field must negative their application;

and that, on the contrary, the surest way of obtaining correct practice is to take care that the shot and shell shall be correctly concentric, and thus extraneous causes of rotation and of uncertain deflections be avoided as much as possible, the direction of that deflection being always the same as that of the rotation of the front of the ball.

It has been already observed that Robins was the first to attribute the usual deviation from the true path of a projectile, to the disturbing influence of the movement of rotation which in general accompanies the movement of translation. Robins and Lombard considered that this deflection was principally the result of the friction of the surface of the ball against the layer of air of unequal density adjacent to it. Poisson investigated the effect of this rotation, in combination with a movement of translation, considering every point of the surface as subjected to a resistance; one portion of which is normal, being the resistance of the fluid or air, properly so called, and the other tangential, being due to friction. When the bullet is perfectly spherical and homogeneous, and on leaving the bore rotates round one of its diameters, the rotatory motion continues during the whole flight in the same direction and round the same axis which remains constantly parallel to itself. The velocity of rotation diminishes in the inverse ratio of the product of the diameter by the density of the ball, but by an extremely small quantity. The deviation, either vertically or laterally, so far as it is due to simple friction, must necessarily be in an opposite direction to that of rotation, as regards the anterior hemisphere; but as this theoretical deduction is opposed to the results of experience, Didion states that the friction arising from rotation does not account either for the direction or amount of deflection. Didion explains the deflection in this way,—assuming the axis of rotation to be vertical, and the moving of the anterior hemisphere from right to left, he says that all the points situated on the right hemisphere move by rotation in the same direction as the centre of gravity moves by translation; whilst those on the left hemisphere move in an opposite direction to that of the centre of gravity, and hence, that the first have a greater velocity in respect to the air than the last, and as the displacement of the air is consequently less easy, the density of the fluid and the pressure resulting from it, are greater on the right than on the left hemisphere.

This explanation appears to imply that the rotation is supposed to add to the normal resistance, whereas the force exercised at any point of the surface, as a result of rotation, can only be tangential. Captain Boxer's explanation, which indeed is also that of Professor Magnus, appears, therefore, to be the correct one, in which he deduces the increased resistance of the air on the right hemisphere as a result of friction;—for example, the air meeting the front of the ball, tends to rush past it both to the right and left, but, pressing with great force against the ball, it is resisted in its passage on the right by the friction consequent on rotation, which is here opposed to the motion of the air, whilst it is assisted in its passage to the left by the friction, the motion being then in the same direction. Of course, the amount of deflection must depend both on the velocity of translation and the velocity of rotation; and hence, when the former becomes 0—the centre of gravity continuing at rest, and the pressure on the anterior and posterior hemispheres being then the same—there can be no deflecting effect produced by rotation. In all these explanations, however, it appears to have been overlooked that, supposing a ball to acquire a motion of rotation within the bore by friction, such friction is only a fraction of the pressure exerted upon the ball in its passage, and, consequently, that the ball must receive a primary impulse of deflection the moment the centre of gravity of the ball leaves the muzzle of the gun. To remedy these evils by rifling of any description, it is necessary that the projectile should be caused to rotate either on the greater or less axis of inertia, as these are the only axes which can remain permanent in space, and that this axis should be coincident with the line of flight. It is very difficult to ensure an exact coincidence of the centre of gravity with the axis of figure corresponding apparently with one or other of these axes; and hence it is that the centre of gravity, moving spirally round the axis on its passage through the rifled bore, receives a certain deflecting influence corresponding to the direction of the spiral groove as it leaves the muzzle—such deflection, however, being necessarily constant as to direction. The experiments of Robins and Hutton had, as before explained, for their object to determine the two most important elements of gunnery, namely, the velocity of the ball on leaving the gun, and the resistance to its progress afforded by the air. Professor Robinson basing his investigation on the deductions made from these experiments, such as that the velocities communicated to balls of the same weight being nearly as the square roots of the weights of the charges; with shot of different weights, fired with the same quantity of powder, the velocities are reciprocally as the square roots of the weights, and when the weights of shot and powder are both different, the velocities are directly as the square roots of the powder, and inversely as the weights of the shot nearly,—proceeds to the important question of determining the ranges, the velocities being known, and lays down as preliminaries the following rules of Robins, the second of which, as has been shown, cannot be admitted; for although an exact duplicate ratio does not represent the ratio of increase in high velocities, there is no such sudden increase as supposed by Robins above the velocity of 1100 feet per second.

1. "Till the velocity of the projectile surpasses that of 1100 feet in a second, the resistance may be reckoned to be in the duplicate proportion of the velocity, and its mean quantity may be reckoned about half an ounce avoirdupois on a 12-pound shot, moving with a velocity of about 25 or 26 feet in a second.

2. "If the velocity be greater than that of 1100 or 1200 feet in a second, then the absolute quantity of the resistance in these greater velocities will be near three times as great as it should be by a comparison with the smaller velocities. Hence, then, it appears, that if a projectile begins to move with a velocity less than that of 1100 feet in 1″, its whole motion may be supposed to be considered on the hypothesis of a resistance in the duplicate ratio of the velocity. And if it begins to move with a velocity greater than this last mentioned, yet if the first part of its motion, till its velocity be reduced to near 1100 feet in 1″, be considered separately from the remaining part in which the velocity is less than 1100 feet in 1″, it is evident that both parts may be truly assigned on the same hypothesis; only the absolute quantity of the resistance is three times greater in the first part than in the last. Wherefore, if the motion of a projectile, on the hypothesis of a resistance in the duplicate ratio of the velocity, be truly and generally assigned, the actual motions of resisted bodies may be thereby determined, notwithstanding the increased resistances in the great velocities. And, to avoid the division of the motion into two, I shall show how to compute the whole at one operation, with little more trouble than if no such increased resistance took place.

"To avoid frequent circumlocutions, the distance to which any projectile would range in a vacuum on the horizontal plane at 45° of elevation, I shall call the potential random of that projectile; the distance to which the projectile would range *in vacuo* on the horizontal plane at any angle different from 45°, I shall call the potential range of the projectile at that angle; and the distance to which a projectile really ranges, I shall call its actual range.

"If the velocity with which a projectile begins to move is known, its potential random and its potential range at any given angle are easily determined from the common theory of projectiles; or, more generally, if either its original velocity, its potential random, or its potential range, at a given angle, are known, the other two are easily found out.

"To facilitate the computation of resisted bodies, it is necessary, in the consideration of each resisted body, to assign a certain quantity, which I shall denominate F, adapted to the resistance of that particular projectile. To find this quantity F to any projectile given, we may proceed thus:—First find, from the principles already delivered, with what velocity the projectile must move, so that its resistance may be equal to its gravity. Then the height from whence a body must descend in a vacuum to acquire this velocity is the magnitude of F sought. But the most concise way of finding this quantity F to any shell or bullet is this: If it be of solid iron, multiply its diameter measured in inches by 300; the product will be the magnitude of F expressed in yards. If, instead of a solid iron bullet, it is a shell or a bullet of some other substance; then, as the specific gravity of iron is to the specific gravity of the shell or bullet given, so is the F corresponding to an iron bullet of the same diameter to the proper F for the shell or bullet given. The quantity F being thus assigned, the necessary computation of these resisted motions may be dispatched by the three following propositions, always remembering that these propositions proceed on the hypothesis of the resistance being in the duplicate proportion of the velocity of the resisted body. How to apply this principle, when the velocity is so great as to have its resistance augmented beyond this rate, shall be shown in a corollary to be annexed to the first proposition.

"Prop. I.—Given the actual range of a given shell or bullet at any small angle not exceeding 8° or 10°; to determine its potential range, and consequently its potential random and original velocity.

"*Solution.* Let the actual range given be divided by the F corresponding to the given projectile, and find the quote in the first column of the preceding table: then the corresponding number in the second column multiplied into F will be the potential range sought: and thence, by the methods already explained, the potential random and the original velocity of the projectile is given.

"*Exam.* An 18-pounder, the diameter of whose shot is about 5 inches, when loaded with two pounds of powder, ranged at an elevation of 3° 30′ to the distance of 975 yards.

"The F corresponding to this bullet is 1500 yards, and the quote of the actual range by this number is ·65; corresponding to which, in the second column, is ·817; whence, ·817 F, or 1225 yards, is the potential range sought; and this, augmented in the ratio of the sine of twice the angle of elevation to the radius, gives 10,050 yards for the potential random: whence it will be found that the velocity of this projectile was that of 984 feet in a second.

"*Cor.* 1. If the converse of this proposition be desired; that is, if the potential range in a small angle be given, and thence the actual range be sought; this may be solved with the same facility by the same table: for if the given potential range be divided by its correspondent F, then opposite to the quote sought in the second column there will be found in the first column a number which, multiplied into F, will give the actual range required. And from hence it follows, that if the actual range be given at one angle, it may be found at every other angle not exceeding 8° or 10°.

"*Cor.* 2. If the actual range at a given small angle be given, and another actual range be given, to which the angle is sought; this will be determined by finding the potential ranges corresponding to the two given actual ranges; then the angle corresponding to one of those potential ranges being known, the angle corresponding to the other will be found by the common theory of projectiles.

"*Cor.* 3. If the potential random deduced from the actual range by this proposition exceeds 13,000 yards, then the original velocity of the projectile was so great as to be affected by the treble, or at least much greater, resistance described above; and consequently the real potential random will be greater than what is here determined. However, in this case, the true potential random may be thus nearly assigned. Take a fourth continued proportional to 13,000 yards, and the potential random found by this proposition, and the fourth proportional thus found may be assumed for the true potential random sought. In like manner, when the true potential random is given greater than 13,000 yards, we must take two mean proportionals between 13,000 and this random; and the first of these mean proportionals must be assumed instead of the random given, in every operation described in these propositions and their corollaries. And this method will nearly allow for the increased resistance in large velocities, the difference only amounting to a few minutes in the angle of direction of the projected body, which, provided that angle exceeds two or three degrees, is usually scarce worth attending to.

"Of this process take the following example:—A 24-pounder fired with 12 pounds of powder, when elevated at 7° 15′, ranged about 2500 yards. Here the F being near 1700 yards, the quote to be sought in the first column is 1·47, to which the number corresponding in the second column is 2·556; whence the potential range is near 4350 yards, and the potential random thence resulting 17,400. But this being more than 13,000, we must, to get the true potential random, take a fourth continued proportional to 13,000 and 17,400; and this fourth proportional, which is about 31,000 yards, is to be esteemed the true potential random sought; whence the velocity is nearly that of 1730 feet in a second.

"*Scholium.* This proposition is confined to small angles, not exceeding 8° or 10°. In all possible cases of practice, this approximation, thus limited, will not differ from the most rigorous solution by so much as what will often intervene from the variation of the density of the atmosphere in a few hours' time; so that the errors of the approximation are much short of other inevitable errors, which arise from the nature of this subject.

"Prop. II.—Given the actual range of a given shell or bullet at any angle not exceeding 45°; to determine its potential range at the same angle, and thence its potential random and original velocity.

"*Solution.* Diminish the F corresponding to the shell or bullet given in the proportion of the radius to the cosine of $\frac{4}{5}$ths of the angle of elevation. Then, by means of the preceding table, operate with this reduced F in the same manner as is prescribed in the solution of the last proposition, and the result will be the potential range sought; whence the potential random and the original velocity are easily determined.

"*Exam.* A mortar for sea-service, charged with thirty pounds of powder, has sometimes thrown its shell, of $12\frac{3}{4}$th inches diameter, and of 231 lbs. weight, to the distance of two miles, or 5450 yards. This at an elevation of 45°.

"The F to this shell, if it were solid, is 3825 yards; but as the shell is only $\frac{4}{5}$ths of a solid globe, the true F is no more than 3060 yards. This, diminished in the ratio of the radius to the cosine of $\frac{3}{4}$ths of the angle of elevation, becomes 2544. The quote of the potential range by this diminished F is 1·384; which, sought in the first column of the preceding table, gives 2·280 for the corresponding number in the second column; and this multiplied into the reduced F, produces 5800 yards for the potential range sought, which, as the angle of elevation was 45°, is also the potential random; and hence the original velocity of this shell appears to be that of about 748 feet in a second.

"*Cor.* The converse of this proposition, that is, the determination of the actual range from the potential range given, is easily deduced from hence by means of the quote of the potential range divided by the reduced F; for this quote, searched out in the second column, will give a corresponding number in the first column, which, multiplied into the reduced F, will be the actual range sought.

"Also, if the potential random of a projectile be given, or its actual range at a given angle of elevation; its actual range at any other angle of elevation, not greater than 45°, may hence be known. For the potential random will assign the potential range at any given angle; and thence, by the method of this corollary, the actual range may be found.

"*Exam.* A fit musket-bullet fired from a piece of the standard dimensions, with $\frac{1}{5}$th of its weight in good powder, acquires a velocity of near 900 feet in a second; that is, it has a potential random of near 8400 yards. If now the actual range of this bullet at 15° was sought, we must proceed thus:

"From the given potential random it follows, that the potential range at 15° is 4200 yards; the diameter of the bullet is $\frac{3}{4}$ths of an inch: and thence, as it is of lead, its proper F is 337·5 yards, which, reduced in the ratio of the radius to the cosine of $\frac{3}{4}$ths of 15°, becomes 331 yards. The quote of 4200 by this number is 12·7 nearly; which being sought in the second column, gives 3·2 nearly for the corresponding number in the first column; and this multiplied into 331 yards (the reduced F) makes 1059 yards for the actual range sought.

"*Exam.* 2. The same bullet, fired with its whole weight in powder, acquires a velocity of about 2100 feet in a second, to which there corresponds a potential random of about 45,700 yards. But this number greatly exceeding 13,000 yards, it must be reduced by the method described in the third corollary of the first proposition, when it becomes 19,700 yards. If now the actual range of this bullet at 15° be required, we shall from hence find that the potential range at 15° is 9850 yards; which, divided by the reduced F of the last example, gives for a quote 29·75; and thence following the steps prescribed above, the actual range of this bullet comes out 1396 yards, exceeding the former range by no more than 337 yards; whereas the difference between the two potential ranges is above ten miles. Of such prodigious efficacy is the resistance of the air, which for so long a time was treated as too insignificant a power to be attended to in laying down the theory of projectiles.

"*Schol.* I must here observe that as the density of the atmosphere perpetually varies, increasing and diminishing often by $\frac{1}{30}$th part, and sometimes more, in a few hours; for that reason I have not been over rigorous in forming these rules, but have considered them as sufficiently exact when the errors of the approximation do not exceed the inequalities which would take place by a change of $\frac{1}{30}$th part in the density of the atmosphere. With this restriction, the rules of this proposition may be safely applied in all possible cases of practice. That is to say, they will exhibit the true motions of all kinds of shells and cannon-shot, as far as 45° of elevation, and of all musket bullets fired with their largest customary charges, if not elevated more than 30°. Indeed, if experiments are made with extraordinary quantities of powder, producing potential randoms greatly surpassing the usual rate, then in large angles some farther modifications may be necessary. And though, as these cases are beyond the limits of all practice, it may be thought unnecessary to consider them; yet, to enable those who are so disposed to examine these uncommon cases, I shall here insert a proposition which will determine the actual motion of a projectile at 45°, how enormous soever its original velocity may be. But as this proposition will rather relate to speculative than practical cases, instead of supposing the actual range known, thence to assign the potential random, I shall now suppose the potential random given, and the actual range to be thence investigated.

"PROP. III.—Given the potential random of a given shell or bullet; to determine its actual range at 45°.

"*Solution.* Divide the given potential random by the F corresponding to the shell or bullet given, and call the quotient q, and let l be the difference between the tabular logarithms of 25 and of q, the logarithm of 10 being supposed unity; then the actual range sought is $3{\cdot}4\,F \mp 2lF - \frac{ll}{10}F$, where the double sign of $2lF$ is to be thus understood; that if q be less than 25 it must be $-2lF$; if it be greater, then it must be $+2lF$. In this solution q may be any number not less than 3, nor more than 2500.

"*Cor.* Computing in the manner here laid down, we shall find the relation between the potential randoms, and the actual range at 45°, within the limits of this proposition, to be as expressed in the following table:—

Potential Randoms.	Actual Range at 45°.	Potential Randoms.	Actual Range at 45°.
3 F	1·5 F	50 F	4·0 F
6 F	2·1 F	100 F	4·6 F
10 F	2·6 F	200 F	5·1 F
20 F	3·2 F	500 F	5·8 F
30 F	3·6 F	1000 F	6·4 F
40 F	3·8 F	2500 F	7·0 F.

"Whence it appears, that, when the potential random is increased from 3 F to 2500 F, the actual range is only increased from $1\frac{1}{2}$ F to 7 F; so that an increase of 2497 F in the potential random produces no greater an increase in the actual range than $5\frac{1}{2}$ F, which is not its $\frac{1}{400}$th part; and this will again be greatly diminished on account of the increased resistance which takes place in great velocities. So extraordinary are the effects of this resistance, which was once considered inconsiderable.

"That the justness of the approximation laid down in the second and third propositions may be easier examined, I shall conclude these computations by inserting a table of the actual ranges, at 45°, of a projectile which is resisted in the duplicate proportion of its velocity. This table is computed by methods different from those hitherto described, and is sufficiently exact to serve as a standard with which the result of our other rules may be compared. And since whatever errors occur in the application of the preceding propositions, they will be most sensible at 45° of elevation, it follows, that hereby the utmost limits of those errors may be assigned.

Potential Randoms.	Actual Range at 45°.	Potential Randoms.	Actual Range at 45°.

These remarkable tables and rules of Professor Robinson do not appear to have been noticed by foreign writers. Hutton makes use of them with some modification in the following manner. First, he determined the greatest terminal velocity which a ball would acquire in falling through the air as exhibited in this table:—

Weight of ball in lbs.	Diameter in inches.	Terminal velocity v in feet.	Height a due to v in feet.	Times of finding falling.
1	1·923	247	948	7·72
2	2·423	277	1193	8·66
3	2·773	297	1371	9·28
4	3·053	311	1503	9·72
6	3·494	333	1724	10·41
9	4·000	356	1970	11·12
12	4·403	374	2174	11·69
18	5·040	400	2488	12·50
24	5·546	419	2729	13·09
32	6·106	440	3010	13·75
36	6·350	449	3134	14·03
42	6·684	461	3304	14·50

And these form a table for determining the elevation which will give the greatest range, the initial velocity being given, and the size and nature of the shot known; which table, he states, is a modification of that of Professor Robinson, founded on an approximation of Sir Isaac Newton.

Table of Elevation, giving the greatest Range.

Initial velocity divided by terminal or v.	Elevation.	Range divided by a, or height due to terminal velocity.
0·6910	44° 0′	0·4110
0·9445	43 15	0·6148
1·1980	42 30	0·8176
1·4515	41 45	1·0210
1·7050	41 0	1·2244
1·9585	40 15	1·4278
2·2120	39 30	1·6312
2·4655	38 45	1·8346
2·7190	38 0	2·0379
2·9725	37 15	2·2413
3·2260	36 30	2·4447
3·4795	35 45	2·6481
3·7330	35 0	2·8515
3·9865	34 15	3·0549
4·2400	33 30	3·2583
4·4935	32 45	3·4616
4·7470	32 0	3.6650
5·0000	31 15	3·8684

To use these tables, divide the initial velocity by the terminal velocity peculiar to the ball, as given in the third column of the first table, and look for the quotient in the first column of the second table, against which, in the second column, is found the elevation which will give the greatest range; and in the third, a number which, being multiplied by a of the first table, gives the range nearly as exhibited by the following example:—

Let a 24-lb. ball be discharged with a velocity of 1640 feet per second. By the first table, the terminal velocity v of a 24-lb. ball is 419, and the altitude producing this terminal velocity, or a, 2729, hence $\frac{1640}{419}=3{\cdot}92$ nearly. Now opposite 3·9865 in the second table stands 34° 15′ as the angle which would give the greatest range, and the corresponding number in the third column, 3·0549, being multiplied by 2729 gives 8336 feet for the greatest range, being rather more than a mile and a half. As it is not customary nor ordinarily practicable to discharge guns at these elevations, these tables can seldom be applied in service; though in the recent campaign it might have been useful to consult them when guns either damaged, or otherwise useless for their ordinary practice, were discharged with great effect at high elevations by either sinking them partially in the earth or by suspending them.

Dr Hutton therefore computed the following table for shells—making allowance for the difference in the terminal velocity consequent on the difference between the specific gravity of the filled shell and the corresponding solid iron ball—to replace the first of the former tables:—

Table of Dimensions, &c., of Mortar Shells.

Diameter of mortar.	Diameter of shell.	Weight of shells empty.	Weight of shells filled.	Weight of equal solid.	Ratio of shell to solid.	Terminal velocity, or v.	Altitude a due to velocity.
in.	in.	lbs.	lbs.	lbs.		ft.	ft.
4·6	4·53	8·3	9	12¾	1·42	318	1580
5·8	5·72	16·7	18	25½	1·42	356	1980
8	7·90	43·8	47	67	1·42	420	2756
10	9·84	85·5	91½	130	1·42	468	3422
13	12·80	187·8	201	286	1·42	534	4430

Using this table, then, instead of the former, and assuming, in the case of a 13-inch shell, that it is projected with a velocity of 2000 feet per second, which is about a maximum, we find in the seventh column, opposite the 13-inch shell, 534; hence $\frac{2000}{534}=3{\cdot}746$; and opposite 3·7330 in the other table will be found 35° as the angle which gives the greatest range, and 2·8518 in the third column which, multiplied by 4430, the altitude opposite the 13-inch shell, gives 12,632 feet, or almost 2½ miles, for the greatest range. The French, however, fired shells at the siege of Cadiz a distance of more than 3 miles, the cavity of the shell being filled up with lead, and Hutton therefore investigated what would be the range of a 13-inch shell if so filled, and found that the range would be 16,005 feet, or 3 miles and 165 feet, the corresponding angle being 37° 20′. Such projectiles, however, were more formidable in appearance than in reality, as they seldom burst, and when they did the explosion was inconsiderable. Dr Hutton makes also another very important reference to the discoveries or reasonings of Professor Robinson, who first pointed out that "balls of equal density, discharged at the same elevation, with velocities proportional to the square roots of these diameters, will describe similar curves; because then the resistance will be in proportion to the momenta or quantities of motion,"—thus v being as $\surd d$, v^2 will be as d; consequently $d^2 v^2$ will be as d^3, but the resistance γ is nearly as $d^2 v^2$, d being the diameter and v the velocity, and hence γ is as d^3, or as the momentum which is as the magnitude of the mass, or as d^3. In this case, then, the horizontal velocity at the vertex, opposite the curve, will be proportional to the terminal velocity; and the ranges, heights, and all other similar lines will be proportional to d—a principle which may be of considerable use; for by means of a proper series of experiments on one ball, projected with different velocities and elevations, tables may be constructed by which may be ascertained the motions in all similar cases.

Dr Hutton gives the following table, deduced partly from theory and partly from experiment, which may be applied on the above principles:—

Table of the Motions of a 24-lb. Shot projected at 45° elevation.

Velocity per second.	Range in vacuo.	Range in the air.	Range corrected.	Height the ball rises to.
200	415	320	330	100
400	1658	1000	1019	300
600	3731	1391	1419	400
800	6632	1687	1719	464
1000	10362	1840	1878	515
1200	14922	1934	1978	561
1400	20310	2078	2129	606
1600	26528	2206	2264	650
1800	33574	2326	2391	694
2000	41450	2438	2510	738
2200	50155	2542	2622	778
2400	59688	2640	2726	816
2600	70050	2734	2823	852
2800	81241	2827	2916	887
3000	93262	2915	3002	922
3200	106111	2995	3086	996

Now, bearing in mind Professor Robinson's proposition if it be required to find the dimensions of the path described by a 12-lb. shot, discharged with a velocity of 1600 feet per second, and at an elevation of 45°. Here, as the curves are similar, and their corresponding lines proportional to the diameters of the shot, when discharged with velocities proportional to the square roots of the diameters, the velocity of a 24-lb. ball, corresponding to the 1600 feet of a 12-lb. ball, is first found in the table. Then, as the diameters of the two balls are 4·403, 5·546, the proportion will be $\sqrt{4{\cdot}403} : \sqrt{5{\cdot}546} :: 1600 : 1796$, the corresponding velocity of the 24-lb. ball, opposite to which in the table are the corresponding ranges and height, 2386 and 692; therefore, as 5·546 : 4·403 : : 2386 : 1894 yards the range, and 5·546 : 4·403 : : 692 : 549 yards the altitude. In like manner, the table may be used for determining the ranges of mortar shells; as, for example, a 13-inch shell, projected with the velocity of 2000 feet per second, at 45° elevation. First, the diameter of the shell being 12·8, the proportion is $\sqrt{12{\cdot}8} : \sqrt{5{\cdot}546} :: 2000 : 1317$; but as the weight of the shell, filled in the ordinary way, is less than that of a corresponding solid shot, this velocity must be reduced in the same manner as was done in page 132, with reference to a previous table; namely, as 178 : 149·4 : : 1317 : 1105, the corresponding velocity of the 24-pounder, to which in the table answers the range 1930; and finally, as 5·546 : 12·8 : : 1930 : 4455 yards, or about 2½ miles.

The difficulty of establishing fixed rules for the ranges of projectiles, an object of great practical importance, will be appreciated from what has been stated; a difficulty, indeed, due not only to the mathematical perplexity of the question as regards the determination of the trajectory of the projectile in a resisting medium like the air—a question which has exercised the ingenuity of the most profound mathematicians, including Euler, Borda, Poisson, Legendre, and many others—but also to the uncertainty of the law of the air's resistance in relation to the velocity of the projectile. By the experiments of Robins, Hutton, and others, with the ballistic pendulum, the velocity close to the gun's mouth, and at short distances from it up to about 250 feet, was determined, and thence the loss from the resistance of the air in passing through such small spaces deduced; but experiments have not as yet been multiplied sufficiently to express the terms of resistance in formulæ which will meet the circumstances of all projectiles. The resistances, too, at low velocities have been generally determined by the whirling machine, which does not strictly represent the circumstances of rectilineal motion; in the latter the resistances vary, with equal velocities, as the surfaces; whereas, in the circular motion, the co-efficient of resistance requires to be increased as the surfaces increase. From the present accuracy of fire of rifled muskets much knowledge might be acquired of the resistances to a small ball, by firing at a properly constructed pendulum, at different distances up to 800 yards; and though it cannot be expected that the precision of fire of larger projectiles will ever allow this distant use of the ballistic pendulum, still the comparison between the loss of velocity in great and small bodies might be founded on much better data than at present.[1]

---

[1] Several ingenious methods have indeed, from time to time, been proposed to measure the velocity by determining the time of the ball's transit through a definite space; thus, for example, the revolving machine of Grobert, which consists of two circular discs of card-board about 6½ feet in diameter, connected together by an axis 13 feet long, to which a rotatory motion is given by means of a band passing over a pulley on the centre of the axis, and connected with a proper combination of wheels to produce the necessary velocity of rotation. The two discs are divided into 360° each by radiating lines, and the axis being placed in the prolongation of the line of flight, the ball passes through both discs whilst rotating with a considerable and uniform velocity; and the angle between the two perforations, as shown by the lines, affords the means of determining the velocity, thus:—let φ be the angle, t the time of a revolution, $\frac{\varphi}{360}t$=the time of passing the distance d between the two discs, and the velocity $v=\frac{360\,d}{\varphi\,t}$. Now if t be $\frac{1}{10}$th of a second, or the machine revolves ten times in a second, and v be assumed=1200 feet, φ would be 39°. Don Tomas de Morla had previously proposed a wheel or cylinder, rotating on the top of a vertical axis, the ball being so discharged as to pass as nearly as possible through a diameter of the cylinder when the angle between the two opposite perforations afforded the means of determining the time of passage and the velocity; but neither of these methods are sufficiently exact for the purpose. Professor Wheatstone, some years ago, proposed the electro-magnetic cronograph to the artillery committee, but his proposition was not then favourably entertained, though it is now again under consideration. The mode in which it has been tried on the continent is as follows:—Two screens or targets of metallic wire twisted *continuously* into a net-work, which the ball cannot pass through without breaking, are set up, the wires being of course coated so as to prevent metallic contact between the parts of the net: each screen, by means of a connecting wire, forms part of the conducting circuit between a voltaic battery and an electro-magnet, which suspends a marker or pencil over a cylinder made to revolve uniformly with the necessary velocity. Now, when the ball passes through the first "target net" the circuit is broken, and the pencil instantly falls upon the cylinder, and makes a recording mark upon it. When the ball passes through the second "net" the connection of the second electro-magnet is in like manner broken, and by the fall of its pencil a similar mark, though on a different point, is made upon the cylinder. The time of revolution of the cylinder being known, the angle between these two marks, as in Grobert's and Morla's machines, determines the time of the ball's passage between the two targets, and hence the velocity of the ball. Though it is said this system has not as yet been perfectly successful, it may now be reasonably expected, from the increased knowledge of electro-magnetic phenomena, and the improvement of electro-magnetic apparatus, that it will be speedily rendered so.

CONSTRUCTION OF GUNS.

In reference to the preceding tables of guns, it is necessary to consider the very important questions connected with their construction. In the first place, it is evident that there should be some relation between the expansive forces of the gases developed by the ignition of the charge of gunpowder, and the tenacity of the metal cylinder or gun which has to resist them; and here again it is necessary to know whether the gases act simply by pressure or by shock. That the action of the gases at the first moment of their development is *analogous* to a shock, or percussive force, is the general belief at present; and indeed, when it is considered that all the particles of matter constituting the retaining tube or gun are in a state of rest, or in a passive condition, when, by the almost instantaneous development of the gases, they are suddenly exposed to the action of a repulsive force capable of impressing on the particles of the gases a velocity of 7000 feet per second, it can scarcely be doubted that they must be affected very much in the same way as they would have been if exposed to the action of a percussive force; though, of course, when once the shock had been transmitted through the solid substance, and the whole of its resisting forces had been called into action, the gases, if brought into a state of rest, would act by simple pressure. Tinmhermans charged a musket barrel with 1·2 oz. of powder, and then in successive discharges increased the resistance each time by adding 1, 2, 3, &c., balls, until the barrel burst, when it was found that whenever the resistance exceeded a certain limit all the barrels swelled out in a narrow annular space, forming a defined border somewhat in front of the end of the charge. Now, it seems certain that if the gases had acted by pressure only, the whole of the bounding cylinder of the bore behind the charge should have swollen out equally, and not have been restricted in the extension of the calibre to the space of a simple ring; from which it was inferred that the gases, acting by shock against the ball, were thrown back by its resistance against the narrow space described. In like manner, Tinmhermans reasons from Swedish experiments made in

1831, in which it appeared that iron guns in which the end of the bore was hemispherical, afforded much more resistance than those ending in a plane surface; that this was due to the difference in the shock consequent on the difference of form in the bodies exposed to the action of the fluids.

Admitting, however, as has been done, the analogy in the mode of action of an *almost instantaneously* developed repulsive force on the walls of the cylinder, which restrains the expansion of the gases which exercise that force, to that of a shock or percussion, the experiments cited do not appear sufficient to establish a perfect identity in such actions. Without doubt, in such a case, time is necessary to enable the resisting body to bring into play its tenacity, and it resists, therefore, at first by the simple cohesive force which binds its particles together, and in this consists the analogy between the action of gunpowder and a percussive force. In considering the first experiment, it must be remembered that at two positions of the bore the destructive action of the gunpowder may be considered greater than at any other—namely, at the section transverse to the axes and immediately in front of the bottom of the bore, as the gases are then acting in two directions perpendicular to each other, namely, against the bottom of the bore or in the direction of the axis, and against the walls of the bore or perpendicular to the axis, thus tending to drag apart the breech from the rest of the gun;—and again at a transverse section somewhat in front of the charge, as the friction of the ball tends in a minor degree to produce a similar effect, and still more so when several balls or other projectiles are used, so as to check the progressive motion of the mass, and to augment the dragging effect of the friction. In this latter case, as the expanding gases would be also checked in their progressive motion, an accumulation would for the instant take place immediately behind the balls, and thus produce an augmented pressure on the sectional ring corresponding to that position, the result being, as in the cited experiment, an annular or local expansion rather than a general one.

On the principle of pressure, however, it does not appear difficult to obtain a reasonable approximation to the required thickness of the containing tube, following the reasoning of Senderos. Let R be the radius of the exterior of a tube or gun barrel, r the radius of the interior, π the proportion between the diameter of a circle and the circumference; then the surface of pressure against the base of the tube acting to produce fracture, at the circumference $2\pi r$, will be the area of that circle, or πr^2. The surface of pressure, equal to the other, but acting longitudinally, will be a rectangle, one side of which is the diameter of the tube, or $2r$, and the other a portion of the length of the tube l, such as will make the two surfaces of pressure equal, or $\pi r^2 = 2rl$, and hence $l = \frac{\pi r}{2}$. Now, the surface of resistance in a direction perpendicular to the axis will be represented by the area of the annular space represented by $\pi\,(\mathrm{R}^2 - r^2)$, and the surface of resistance in a longitudinal direction, by the areas of the two surfaces, one at each end of the diameter corresponding to the two fractures along l, that is by $2l\,(\mathrm{R} - r)$. Now, comparing these two together, the resistances being proportional to the surfaces of fracture, they will be as $\pi\,(\mathrm{R}^2 - r^2) : 2l\,(\mathrm{R} - r)$; or substituting the value of l, as $(\mathrm{R}^2 - r^2) : r\,(\mathrm{R} - r)$, and making $\mathrm{R} - r = d$ as $d(\mathrm{R} + r) : dr = d\,(d + 2r) : dr = d + 2r : r$; which shows that the resistance to fracture in a transverse direction, or perpendicular to the axes, is always much greater than that in a longitudinal direction, being indeed four times as great when $d = 2r$, or one calibre—not, however, making the comparison with a transverse section close to the bottom of the bore, for the reasons before stated. The pressures and resistances may now be compared together, and for this comparison the tenacities of wrought iron and of the best bronze have been stated by Senderos as 4234 and 3872 atmospheres respectively, and the cohesive force of cast iron as 1358. According to the experiments of Navier, these numbers should be $4164\frac{1}{2}$, 2475, and 1307, and by others the cohesive strength of wrought and of cast iron have been stated at 4166 and 1266 atmospheres. With these data, equalizing the pressure tending to produce fracture in a longitudinal direction—that is, to force one half of the cylinder to separate from the other in two longitudinal fractures of the length l—to the force of cohesion resisting fracture, P representing the pressure and C the tenacity or cohesion—we have, as before explained, $2rl\,\mathrm{P} = 2l\,(\mathrm{R} - r)\,\mathrm{C}$, or $r\,\mathrm{P} = (\mathrm{R} - r)\,\mathrm{C}$, or $r\,\mathrm{P} = d\,\mathrm{C}$. But C in English cast iron is 1266 and $\mathrm{P} = 2230$; hence $r\,2230 = d\,1266$, or $d = \frac{2230}{1266} r = 1{\cdot}76\,r$, or about $\frac{7}{8}$ths of a calibre, which is the thickness adopted for shell guns, but $\frac{2}{8}$ths less than the thickness of the heavy iron guns.

It must, however, be remembered that the cohesive forces stated ought not to be admitted in practice, as they are liable to be affected by heat and other causes; and hence, if only $\frac{1}{3}$d be deducted from the cohesive force, d would become $= 2 \cdot 6\,r$, or $1\frac{3}{10}$ths calibre, which is greater than the maximum thickness adopted, or that at the breech. With bronze of 2475 tenacity, and reducing by one-third, the thickness would be about $\frac{6}{8}$ths calibre, the adopted thickness being $\frac{7}{8}$ths. With wrought iron, taking the English estimate, and deducting $\frac{1}{3}$d, the thickness should be about $\frac{5}{16}$ths of a calibre—the actual thickness of metal at the breech of an artillery carbine being very nearly that deduced from theory, or $\frac{1}{5}$th of a calibre. It is not to be wondered that this great saving in thickness or in weight of metal has so often led to trials of wrought iron for guns, though the great difficulty of forging such large masses has hitherto checked the extension of its use; and further, it will be shown that a certain weight is absolutely necessary for a gun, and that the use of wrought iron, therefore, is only desirable when peculiar lightness or peculiar strength are indispensable.

General Construction of Iron and Brass Guns.

Form, Weight, and Length.—Having arrived at a tolerable knowledge of the thickness of metal necessary to resist the first shock of the gunpowder, it becomes comparatively easy to resolve most of the other elements of construction. By the law of Mariotte, for example, the pressure of gases varies directly with their densities, or inversely with the spaces they occupy; and hence the pressure, when the gases have expanded so as to occupy twice the space, will be one-half; or three times the space, one-third; and so on. This law appears to have been practically followed from an early period, as the external form has been made more or less conical, and generally indeed such as to constitute three truncated cones, corresponding to the first reinforce, second reinforce, and chase of our ordnance, though sometimes the two first have been united either into one cylinder or one truncated cone, which is an arrangement more consonant to theory. In considering the portion of the bore to which the greatest thickness of metal should be extended, it is necessary to know the position of the ball at the moment when the gases developed are in the highest state of condensation, and this has been assumed by many to be when the ball has moved forward a length equal to its own radius; and farther, to assume the greatest length of charge ever intended to be used with the gun, which therefore need not exceed either that of the proof charge, or of the charge which would produce the greatest initial velocity in a ball. In the 24-pounder the proof charge is $\frac{3}{4}$ths of the weight of the ball, in the 32-pounder about $\frac{11}{16}$ths, the 42-pounder about $\frac{5}{8}$ths, the 56-pounder $\frac{1}{2}$, the 68-pounder about $\frac{7}{16}$ths, the 18-pounder $\frac{5}{6}$ths, and the 12-pounder and smaller guns equal to the weight of the ball. In the 68-pounder the charge for producing the maximum velocity by the table of Hutton would be $43\frac{1}{4}$ lbs., whereas the proof charge may be taken at 28 lbs. On the former supposition, the length of the cylinders exposed to the maximum action of the gunpowder would be $27\frac{1}{2}+4$ inches $=31\frac{1}{2}$, or 2 feet $7\frac{1}{2}$ inches, which would extend about half-way from the termination of the first reinforce to the trunnion; and it may be remarked, in reference to this point, that the fractures on the bursting of a gun extend longitudinally, in somewhat irregular or curved lines, rather beyond the trunnions—the breech being partly broken off near the bottom of the bore on the one end, and the chase being separated from the other part of the gun on the other. With the length of the 68-pounder of 95 cwt., the whole volume of the bore, as compared to that of the maximum velocity charge, is not quite 4 to 1;—so that if 3 to 1 be adopted, the thickness at the muzzle ought to be $\frac{3}{8}$ths of a calibre. If, then, without regard to ornament, the gun were constructed upon the simple principle of a cylinder extending from the extremity of the breech to the point on the second reinforce above intimated, and from that point to the extremity of the muzzle as a truncated cone, the 68-pounder of 15 calibres would weigh 103 cwt., being the mean between the two heavier 68-pounders, one of which is 112 cwt. and the other 95 cwt., whilst the ratio between the weight of the ball and the weight of the gun would be 1 : 170.

As the weight must therefore depend, first, on the thickness of metal necessary to resist the greatest expansive force of the gunpowder intended to be applied; and secondly, on the length of gun—an element in itself depending on the charge to be used, and the initial velocity to be given to the ball—it becomes necessary to determine the length to be adopted, which is generally stated in calibres as well as in feet and inches. In the early periods of artillery every founder seemed to adopt his own fancy, and hence the variety of guns was not only great as regards the calibre, but also in reference to the length of guns of the same calibre. Some of the guns were of either monstrous size or form. Luis Collado, mentioning a culverine mounted at Naples, and firing a ball of 48 lbs. weight, which was 47 calibres in length, and the *double* cannons founded by order of the Castellan of Milan, Don Alonso Pimentol, which were 130 calibres in length; and he mentions that in his time at Milan no less than 200 varieties of ammunition were required for the service of the artillery of the castle alone. The following table of Venetian guns in the beginning of the sixteenth century is a further example of this apparently capricious multiplication of species:—

Table of the different Pieces of Artillery mentioned in the 11*th Colloquy*, 1*st Book of Tartaglia.*

Description.	Length.		Weight.			Weight of ball.	Remarks.
	ft.	in.	cwt.	qrs.	lbs	lbs.

	9	$6\frac{3}{4}$	26	2	10	66·2	Do.
Cortaldi......	7	$10\frac{1}{2}$	16	0	21	29·8	Do.
Cortaldi......	8	$5\frac{1}{4}$	9	1	23	19·9	Do.

This great variety of pieces of artillery was classed, according to Collado, by the early writers under three heads—1st, Those for long ranges; 2d, Those for battering; 3d, Those for throwing one or more stone balls. The first, of 32 calibres, comprised muskets, falconettes, medium sacers and sacers, aspics, medium culverins, culverins, &c. The second, or battering cannon, are distinguished as quarter guns, medium guns, simple common guns, reinforced and bastard guns, the serpent, double guns, basilisks, &c. These varied in length from 18 to 28 calibres. The third genus included the ancient bombards, mortars, and brass guns, with detached chambers which were fixed to the guns after being charged, as well as the guns for firing stone balls. They were heavier than those of the preceding genera, but were proportionally shorter, not exceeding $8\frac{1}{2}$ calibres in length. This attempt at classification was not, however, adhered to by all the founders of guns, and hence it became absolutely necessary to take some step to lessen the confusion. At the beginning of the seventeenth century, therefore, Christobal Lechuga attempted to reduce the vast number of existing guns to six different calibres only, and shortly afterwards Don Juan Bayarte fixed the number, which were afterwards called guns of regular calibre or of ordinance. This great progressive step of the Spanish artillery was imitated by the other European Powers, by whom the species, dimensions, and calibre of the guns to be retained were established by regulations of state, and were hence called ordnance. Cannon may naturally be divided into two great classes—namely, guns for firing solid shot, and mortars for firing shells or hollow projectiles; but an intermediate genus, partaking of the characters of both, has been interposed, namely, the howitzer, which is manipulated like a gun, but is used for the discharge of hollow projectiles. Lechuga adopted at first the calibres of 40, 24, and 12-pounders, calling the two latter medium and quarter guns, but afterwards added the 16, 8, and 2-pounders. The 40-pounder was rejected by Diego Ufano and Bayarte, and subsequently the calibres fixed by the French Ordinance of 1752 were adopted in Spain—namely, the 4, 8, 12, 16, and 24-pounders for land service, and the 6, 12, 18, 24, 32, and 36-pounders for the marine; but the 4-pounder was subsequently abandoned. Gribcauval was the great reformer in 1765 of the French artillery, when, for siege and fortress guns in brass, 24, 16, 12, 8, and 4-pounders were retained, and for field guns the 12, 8, and 4-pounders; but in the eleventh year of the Republic the list was reduced to the 24-pounder, short; 12-pounder, long and short; 6-pounder, long, short and light or field, mountain; 3-pounder; and 24-pounder howitzer; and, as is well known, the present Emperor of the French has put upon trial a still more simple arrangement, having invented a howitzer gun something like the Licorne of the Russians, and thus endeavoured to reduce calibres to a minimum. In our own service the list of guns shows that there is still a superfluity of species, or rather varieties, and that many must be considered merely experimental; as, for example, of the 68 and 42-pounder, and still more of the 32 and 24-pounder: but some of these have already been practically abandoned.

Not only does the powder, as it progressively burns, continue by successive shocks to act against the ball, but also the gases, as they expand, continue to act upon it, though with a regularly diminishing force. This variable but diminishing accelerating force is opposed to the resistance of the ball from friction in the bore, which is uniform, and by the resistance of the air, which is variable, but increasing as the velocity of the ball increases. Whenever, therefore, the sum of the retarding forces has become equal to that of the accelerating forces, it is evident that no further advantage can be obtained by the action of the gases, and hence that the limit of length has been attained. Capt. Boxer cites the experiments of Col. Armstrong (1736), who endeavoured to determine this question by the ranges obtained. He used a brass 24-pounder, 10 feet 6 inches long, which was shortened by 6 inches after each trial, and the mean ranges he obtained were—for the length of 10 feet 6 inches, 2502; for 10 feet, 2512$\frac{2}{3}$; for 9 feet 6 inches, 2564$\frac{1}{3}$; for 9 feet, 2617$\frac{2}{3}$; for 8 feet 6 inches, 2514; and for 8 feet, 2453$\frac{2}{3}$; from which it appeared that the greatest ranges were obtained from the gun of 9 feet, or 18$\frac{1}{2}$ calibres. Dr Hutton's experiments, before noticed, with the ballistic pendulum, showed that, as regards the initial velocities, they continue to increase with the length of the bore, but in a much less proportion. By Piobert's first quoted series of experiments, or those made in Hanover in 1785, cited also by Capt. Boxer, it appeared that with a charge equal to half the shot's weight, no advantage in point of range was obtained by increasing the length beyond 18 to 24 calibres; and by his second series of 1801, beyond 18 or 19—though in the trials with a 6-pounder, the 15 calibre and 12 calibre guns were very little inferior to the 18 calibre. Capt. Boxer, whilst remarking on the uncertainty as to the absolutely best length of gun, as exhibited even in these extensive experiments, points to a curious law observed in examining these ranges by Mr J. F. Heather, M.A., one of the very able mathematical masters of the Royal Military Academy—namely, that the ranges obtained from guns of 12, 15, and 19 calibres are relative maxima, being greater than those of the guns of intermediate lengths; and he adds that the Hanoverian experiments point to another such maximum in guns of 23 calibres. Reflecting on the experiments of Hutton, and on the general theory of the accelerating and retarding forces already noticed, it seems impossible to connect such alternations with the action of the gases, and they can only be accounted for by some modifying cause, such as the zig-zag motion of the ball within the bore, causing it to range further, or *vice versa*, according as the last rebound may discharge it in a direction passing above or below the axis of the piece. Although, perhaps, not fully conclusive, and still meriting further and very careful experiments, it may for the present be assumed that there is little reason for exceeding 19 calibres in length, or for going below 12, so far as the effective working of the gun, as manifested in its range, is concerned. The lesser number of calibres is best fitted for guns of large calibre, and the greater number for those of small calibre. Assuming then, as has been done, 15 calibres for the 68-pounder, and resolving the gun into two parts—a cylinder and a truncated cone—with a reinforce in rear of the charge, another at about half a calibre in front of it, and a third at the muzzle, a simple and apparently an effective gun would be obtained of moderate weight; and the same would be the result with other guns. In the particular case of the 68-pounder, as the proof charge is about $\frac{2}{3}$ds of the charge which gives the greatest initial velocity, the length of the cylinder, or breech section, might be diminished, and the muzzle or chase, or conical section, increased, by which the weight would be diminished; but as a general rule, the other appears the most satisfactory, as the proof charge is usually $\frac{2}{3}$ds of the weight of the ball.

Impossible to diminish the weight of the gun beyond a certain limit.—It would be wrong to pass from the important subject of the construction of guns without noticing the necessity of securing the carriage of the gun from too severe a shock; and this can only be done by bestowing upon the gun itself a considerable weight, or by interposing springs, which must be very difficult if not impossible in practice. This will be readily understood from the following considerations. Let W be the weight of the gun, and w that of the carriage, and WV the momentum of the gun, on first receiving the shock, and before it has acted on the carriage; now, in hard bodies, when one in motion strikes another at rest, the whole quantity of the motion of the two bodies after the shock will equal that of the first before the contact; hence, taking v as the common velocity of the gun and carriage after the shock, or velocity of recoil of the compound body, $(W+w)v=WV$. Further, the momentum of the gun on receiving the first shock of the powder cannot be altered by diminishing its weight, as the velocity would increase in the same proportion; and supposing W' and V' the new weight and velocity, $W'\,V'=WV$; and in like manner as $(W'+w)$ would then be less than $(W+w)$, so v', or the velocity of $(W'+w)$ would be greater than v, and in consequence $v'w$, or the momentum communicated to the carriage itself, greater than vw, or the motion communicated when the gun weighed W. Every diminution, therefore, in the weight of the gun increases the shock upon the carriage. And if to preserve the amount of recoil within a reasonable limit, and to increase the power of resistance of the carriage, its weight should be increased as much as that of the gun had been diminished, say by n, then the momentum of the gun and carriage would be the same as before; and the velocity, as in the first assumption, v. But this would be composed thus $(vW-vn)+(vw+vn)$; so that the carriage would have received the shock of the additional force represented by vn, and have suffered accordingly, as it is impossible to transfer the momentum of the gun to the gun and carriage without some portion of it being lost in destructive action upon the carriage, a portion which will necessarily increase as the amount of the force expended on the carriage is increased. The greater, therefore, the weight of the gun as compared to that of the carriage, the less will be the loss of force in the transmission of momentum, and of course the less injury done to the carriage. This being considered, it is evident that though by the use of wrought iron, the weight of the gun might be diminished by nearly $\frac{2}{3}$ds, it would be impossible in ordinary guns so far to diminish the weight without the introduction of other means to protect the carriage from injury. In field guns, where the recoil is of less importance than mobility and durability, wrought iron seems the very best material which could be used; and, in like manner, where the object is not a great range but a large calibre, as in flank guns, it might be advisable to replace such guns as short 24-pounders, by wrought-iron 68-pounders, or by cast-iron guns of large calibre but diminished thickness of metal, strengthened by wrought-iron hoops, as in the gun of Captain Blakeley, R.A. Hereafter, more may be expected; and a travelling 68-pounder constructed of a wrought-iron cylinder, sliding on a cast-iron bed, but checked in its motion by springs or buffers—the bed itself being supported on the carriage—the gun, or cylinder, being carried separately from the bed and carriage; guns of such large calibre might then enter into ordinary siege equipments. The monster gun of the Mersey Foundry is of wrought iron, but as its weight will be 24 tons 7 cwt., and the weight of its solid shot 300 lbs., it is rather a triumph of forging than an example of diminished weight, the proportion of the weight of gun and shot being 180 to 1. It is only further necessary briefly to state the proportions between the weights of the ball and of the gun, or between the weights of the charge of powder and of the gun, most generally adopted. In Spain the proportion between the weights of the gun and the charge in long guns is between 800 and 947 to 1; and in short, or field guns, about 480 to 1; or between the gun and ball from 234 to 313 to 1; and in short or field guns, about 142 to 1. In France the proportion in the naval 36-pounder is as 214 to 1; in the 30-pounder, 221 to 1; and in brass guns about 160 to 1. In the United States, from 299 to 1 in the iron 12-pounder, to 201 to 1 in the 42-pounder; but in their 12-feet and 10-feet columbiads, the heaviest of their ordnance, as they weigh 15,400 lbs. and 9240 lbs. respectively, the proportion is as 137 to 1. In brass guns it is as 147 to 1. In our own service, in the three forms of 68-pounder, the longest of which weighs 112 cwt., the proportions are 184, 166, and 143 to 1; in the 42-pounder, between 224 and 179 to 1; in the 32-pounder, between 223 and 140 to 1; in the 24-pounder, 233 and 154 to 1; in the 18-pounder, 261 and 124 to 1; omitting some of the very light and bored-up guns, which can only be considered exceptional cases. In the brass guns, the proportion in the light 6-pounder is 112 to 1; and in the 9-pounder and 12-pounder medium, 168 to 1. So that, taking the guns really effective for all purposes, the weights of brass and iron ordnance are nearly proportional to their respective tenacities. In the Spanish guns, however, the weights of the garrison and siege guns of bronze are as great in proportion to the ball as our iron guns—a striking illustration of the necessity, with the present system of carriage, of retaining a due weight for the gun. In addition to the bearing of the effective action of the powder, &c., on the length of the gun, as before explained, it is well to bear in mind that there is a minimum limit in respect to those guns intended to fire through embrasures, as it is necessary that the muzzle should enter at least 2 feet into the embrasure to prevent its rapid destruction by the concussion consequent upon the discharge. If, then, the trunnions be placed at $\frac{4}{7}$ths of the whole length of the gun from the muzzle, and the radius of the wheel of the travelling carriage be 2 feet 6 inches, the minimum length is given by this simple equation, $\frac{4}{7}$ths $x-2$ feet 6 inches $=2$; or $x=7$ feet $10\frac{1}{2}$ inches. So that 8 feet may be taken as the minimum in this respect.

Preponderance.—If the axis of the trunnions of a gun were fixed in the line passing through its centre of gravity, great instability would be the result, and consequent uncertainty of fire, as the shock of the ball against the bore would be sufficient to disturb its equilibrium; and the ball would be liable to disturbance, even before firing, from many accidental causes, when the front of the gun could be so easily moved vertically. The weight of metal, therefore, behind the trunnions always exceeds that before, and this excess is called "preponderance." In the Spanish ordnance this excess in garrison and siege guns is $\frac{1}{17}$th; in field guns, $\frac{1}{12}$th; and $\frac{1}{7}$th or $\frac{1}{8}$th in howitzers, excepting the mountain howitzer, in which it is about $\frac{1}{10}$th of the weight of the whole piece. Piobert gives the preponderance in the heavier guns as 8 or 9 times the weight of the projectile; in field guns as 12 to 13 times; and in howitzers as 6 to $7\frac{1}{2}$ times that weight. Tinmerhans deduces from general practice a preponderance varying from $\frac{5}{100}$ths to $\frac{12}{100}$ths of the weight of the gun. In the British artillery the preponderance is very various, being $\frac{1}{14}$th, $\frac{1}{13}$th, $\frac{1}{12}$th, $\frac{1}{11}$th, $\frac{1}{10}$th, $\frac{1}{9}$th, $\frac{1}{8}$th, $\frac{1}{7}$th—the result in some measure of the great number of pieces of the same calibre, though it is evident that it ought to be reduced in most cases, as excess of preponderance in heavy guns greatly increases the labour of adjustment. The position also of the axis of the trunnions is, as represented by the circles on the figures of Plate II., below the axis of the gun, a position which causes a rotation on the trunnion, and hence a pressure upon the elevating screw, which is useful also in securing steadiness.

MANAGEMENT OF GUNS.

Laying a gun includes two operations—pointing and elevating. By pointing is understood the placing it in such a position that the axis of the piece shall be exactly in the vertical plane passing through the object aimed at; and by elevating a gun is understood the placing it at such an angle above the horizontal line as will counteract the force of gravity, and thus cause the ball to strike the object aimed at. When a gun is both pointed and elevated, it is said to be laid. The line-of-metal is a visual line extending from the summit of the base-ring to the swell of the muzzle. Its position is ascertained by placing the trunnions perfectly horizontal, and then finding the highest point both on the base-ring and the swell of the muzzle, when the line joining those two points will be the line-of-metal. But in consequence of the conical shape of guns, this line has an inclination to the axis of from one to two or more degrees, which is called the dispart. In pointing a gun, the line-of-metal is first laid in a line with the object; then, if the trunnions are horizontal, the axis of the piece and object will be in the same vertical plane; but if the trunnions are not perfectly so, the continuation of the line-of-metal will cross that of the axis of the piece, and the shot will be thrown to that side of the object on which the lowest trunnion is. As the axis of the gun would not be in the same horizontal plane as the object when the gun had been pointed by the line-of-metal, but elevated above it by the angle of dispart, a dispart sight is placed either on the muzzle, or, according to General Millar's plan—which is now universally adopted in heavy guns—on the second reinforce; so that the visual line becomes parallel to the axis of the gun, and when laid point-blank, however much one trunnion may be lower than the other, the shot cannot be thrown more than the thickness of metal to the right or left; but when elevated it is subject to the error pointed out. A gun is said to be point-blank when the axis of the piece is in a line with the object fired at, without having any elevation or depression, or when the axis is parallel to the horizon; it is desirable also that the platform should, if possible, be laid horizontal. The elevation required to strike any object is found by ascertaining its distance. For this purpose sets of tables have been constructed from actual practice (see Tables at the end), by reference to which the different sorts of shot and shells may be projected with the greatest accuracy.

A scale made of brass, and called a tangent scale, in French, hausse, being marked with the different lengths of the tangents for the several degrees, slides up and down in the breech. By means of this the elevation may be given without any reference to the difference between the level of the gun and the object fired at, and it may be elevated and pointed at the same time. In guns which have disparts, the tangent scale only comes into use at a greater angle than that of the dispart of the gun. Degrees are therefore marked upon the base-ring, beginning at the quarter sight, by means of which the gun may be elevated at any less angle than that of the dispart.

The ·21 of an inch is the tangent of one degree to every foot of the gun's length, from the base-ring to the swell of the muzzle; and therefore, if the distance in feet between those two points, or between the base ring and the sight, be multiplied by ·21, the product will be the tangent of 1° in inches, which, when the dispart is subtracted from it, will give the length of the tangent scale above the base-ring at one degree of elevation for that particular gun, or when the dispart exceeds the tangent of 1°, and is subtracted from the natural tangent of 2° on the scale, the length of the scale at 2°: when, however, a middle sight is used, the elevation can of course be given by the tangent scale from 0° upwards to about 5°. If the scale be applied to the quarter sight of the gun, of course the dispart need not be subtracted.

Elevating guns at sea has always been attended with difficulty and uncertainty. To effect this, the following method has been proposed:—Let the trunnion of a gun be divided by lines passing through its centre, parallel and perpendicular to the axis of the piece, and the lower limb be divided into degrees, &c.; a plumb suspended from the centre of the trunnion will cut the degree of elevation or depression the gun is pointed at, which of course is always varying, from the motion of the ship. If the axis of the piece, therefore, be parallel with the deck, the degree of the inclination of the deck and gun will at the same time be ascertained, and the gun will be fired at the moment when the plumb-line cuts the proper degree marked upon the lower ring of the trunnion. Great accuracy may thus be attained at sea.

A scale has of late years been sometimes used for iron guns, marked with the number of yards range instead of degrees; and this has been found very useful to men who might not perhaps understand the tangent scale. It would unquestionably be very useful to mark approximately on the tangent scale opposite the degrees the number of hundred yards of range;—thus, for example, in the 9-pounder, $1^\circ=4$, $2^\circ=5$, &c.; and in the 24-pounder, of 50 cwt., $1^\circ=7\frac{1}{2}$, $2^\circ=11\frac{1}{4}$, $3^\circ=14\frac{1}{4}$, $4^\circ=16\frac{1}{2}$, $5^\circ=18\frac{1}{2}$ hundreds, &c.; and this is indeed the more necessary where there are several varieties of the same gun differing as to length from each other, as it becomes almost impossible to commit to memory the ranges corresponding to the elevation in each species; and great loss of time, and chance of confusion, would be avoided by thus avoiding the necessity of a reference to printed tables of ranges in the field. In marking the tangent scale, regard should be had to the mean rise of the ball on leaving the gun, referred to in treating of deviations, or else allowance should be made for it. Another mode occasionally used by the French is by the depression of the breech, and is thus effected: A line being drawn through the centre of the trunnion to the extremity of the button of the cascabel, the length of this line becomes a radius for determining the lengths of the natural tangents corresponding to the degrees of a new tangent scale; and these being marked on a long rule, the zero point being the point of contact of the rule and button, when the rule is resting on the platform, and the axis of the piece is horizontal, and the degrees or tangents being numbered from 0° downwards—a very convenient mode when in night-firing at a breach, for example, it is only necessary to secure the elevation. It may be here observed, that by using the middle sight in our iron guns, it becomes impossible to use the angle of dispart. This might be avoided by perforating the sight, and thus enabling the gunner to use the angle of natural aim, which angle, with its corresponding range, ought to be marked on each gun.

Another method, when it is required to fire continually at the same object—for instance, a breach—is, after discharging a few rounds, to observe some object which the gun points to when at the proper elevation, and always point at that object. This is called pointing at a false object.

The modes of pointing and elevating here described are used in guns, howitzers, and carronades. In respect to the first of these it will be observed, that since Colonel Paixhans proposed his *canons à bombes*, the tendency has been to return back to guns of large calibre, for a long time almost abandoned, and only partially revived in carronades; and this change is unquestionably one of great importance to the defence, and will be equally so to the attack, when the difficulty of transporting such heavy weights has been in some degree overcome. In our service at present the heaviest solid shot proposed to be used is that of 68 lbs., and there are three varieties of it, as shown by the table, of which perhaps the 112 cwt. and the 95 cwt. (or Dundas gun) are the best; but for throwing hollow shot—differing from shells by being cast concentric—or shells, there is a 10-inch as well as an 8-inch gun, these guns corresponding in their object with the canon-obusier of the French. Plate II., fig. 1, represents the 68-pounder, and fig. 2 the 8-inch gun—a shell gun, as it is commonly called, the length and weight being greatly inferior to the 68-pounder, though nearly of the same calibre. The shell guns are admirably fitted for coast batteries, as their moderate weight renders them more easily manageable than the 68-pounder, whilst the magnitude of their calibre, whether hollow shot or shells be used, renders their fire very destructive to ships. It is to be observed also, that in coast batteries space alone requires consideration; whilst in ships weight is an equally essential element, as a vessel which could carry on her broadside only eleven 8-inch guns, might be armed with fourteen 32-pounders; and as Sir Howard Douglas therefore reasons, the magnitude of the fractures being taken as the squares of the diameters, or as 704 to 506, whilst the number of shots will be as 11 to 14, the actual spaces opened or fractured will be as 7744 to 7084, or considerably in favour of the 8-inch gun; but, on the other hand, the fire of the 32-pounder would be spread over a much larger space, and be more destructive as to the men; so that it is probable Sir Howard is justified in considering that the greater number of shots from the 32-pounders more than counterbalances the greater space of fracture from the fire of the 8-inch guns. Another reason which induces Sir Howard to object to the too exclusive arming of ships with 8-inch guns is, that the 32-pounders may commence double-shotting at 400 yards; whereas the 8-inch guns cannot commence effective firing with two shots at a greater distance than 200 yards; so that between 400 and 200 yards the 32-pounder armament would have the advantage. On land, however, the number of guns would be the same in either case; and the 8-inch gun, mounted on the dwarf-traversing platform (Plate III., fig. 1), is deservedly a favourite, being associated either with the 68-pounder for longer ranges, or with the 32-pounder. (Plate II., fig. 3.) It will be observed that the shell guns (fig. 2) are *chambered* on the Gomer principle; but this system of construction will be further noticed in treating of howitzers. For field batteries the favourite brass gun of our service is the 9-pounder (Plate II., fig. 4, and Plate III., fig. 7), but these are associated with the 24-pounder brass howitzer (Plate II., fig. 7); so that in the same battery two different calibres are in use, and consequently two different classes of ammunition. The present Emperor of the French has done away with this complex construction of batteries, and has adopted one form of gun—namely, the 12-pounder howitzer gun—fitted for discharging three kinds of projectiles—namely, solid shot, shells, and case shot, and thus requiring only one form of carriage. The principles upon which this great simplification has been adopted have been described by Captain Favé of the French artillery, whose work has been well translated by Captain Hamilton Cox of the Royal Artillery. They are the principles frequently referred to in the preceding pages—namely, that though a greater initial velocity may be obtained by a greater charge, the resistance of the air so rapidly diminishes high initial velocities, that the ultimate ranges and the ultimate momentum are very little superior to those obtained from a considerably less initial velocity. This is illustrated by a reference to Piobert's tables, by which it appears that a 12-pounder, discharged with a velocity of 1610 feet per second, corresponding to a charge of $\frac{1}{3}$d the weight of the ball, retained a velocity of 1516 at a distance of 164 feet, having therefore lost in that short space a velocity of 94 feet per second; whilst, by experiments made at Metz in 1836 and 1840, a 12-pounder shot, fired with a charge of $\frac{1}{4}$th, had an initial velocity of 1516 feet per second; so that the ball propelled with a charge equal to $\frac{1}{4}$th the weight of the ball on leaving the gun was much in the same condition as to velocity as the ball propelled with $\frac{1}{3}$d at 164 feet from it—the two trajectories from these respective points being the same. It is indeed only where great momentum is required at a short distance from the gun that great charges become effective; and for the purposes of field guns there seems great strength in the reasonings which have led to the adoption of the 12-pounder howitzer gun by the French, as, in addition to what has been stated, a French battery is equally effective when called upon to fire shot, shell, or case; whereas, in the compound British battery, the howitzers are so much deducted from its strength when solid shot firing is required; and, in like manner, the guns are a loss when howitzer firing becomes the most valuable. The calibre of a 9-pounder would be too small for fulfilling all the purposes of shot and shell; and hence the French have wisely adopted the 12-pounder, and might perhaps have gone even higher in calibre, reducing the weight of their gun by a corresponding reduction in the weight of the charge.

Howitzers.—This form of ordnance is of later date than the mortar, which will be presently noticed, and was designed for the purpose of firing shells in the field, for which object it was necessary that it should be mounted upon a carriage, so that it combines in itself the functions of the gun and mortar. As the charges for the service required from howitzers are small, so are their comparative weight; for example, whilst the 24-pounder gun of 18$\frac{1}{2}$ calibres weighs 48 cwt., and is charged with 8 lbs. of powder, the 24-pounder howitzer weighs only 12$\frac{1}{2}$ cwt., and is charged with only 2$\frac{1}{2}$ lbs. of powder; and in like manner, whilst the 8-inch shell gun of 13 calibres weighs 65 cwt., the 8-inch howitzer weighs only 20 cwt. The use of such small charges renders it necessary to adopt chambers—that is to say, spaces either entirely or in part of less diameter than the bore itself, as the small cartridge containing the charge could not be so placed in a large bore as to prevent great irregularities in the relative position of the cartridge and ball. Chambers of various forms have been at different times contrived; and, according to the principles adopted by Piobert, their relative values may be thus stated, taking into account the position of the vent, or of the point of the charge at which the inflammation is first set on foot;—1st, Spherical, conical, or pyramidal, when the vent communicates with the surface of the first and base of the two last, and the truncoconical ranks with these when fired at its *greater* base. 2d, Cylindrical, when fired by the lateral surface. 3d, Cylindrical, when fired from either base. 4th, Trunco-conical, when fired from its *lesser* base. 5th, The spherical, conical, or pyramidal, when fired at the exact centre of the first or vertices of the other two: or, merely classifying the forms in general use—1st, spherical; 2d, cylindrical; 3d, trunco-conical. The Gomer form in which the truncated cone is terminated by a spherical end, is that used in the howitzers (Plate II., fig. 6), and the mortar (Plate II., fig. 9), as well as in the shell-gun. In the carronade (fig. 5) the chamber is cylindrical, being terminated by a spherical end; and such was its form in the great Antwerp mortar (fig. 10). It may also be added, that by adopting a chamber a greater thickness of metal is obtained around the charge in ordnance which are comparatively thin from their lightness. Experiments were made in France at Strasburg, Douay, and Toulouse, to ascertain whether the lodgment in the bore produced by the pressure of the gases on the ball, an important consideration in brass guns, could be lessened or obviated by a peculiar position of the vent. One was placed in the prolongation of the axis, the cascabel being suppressed so as to fire the charge in the centre of its extreme end; the second in a line, making an angle of 30°, with the vertical drawn from the extremity of the axis, and the third in the usual way. The destructive effect of the charge in producing a depression in the bore was found to be nearly in the proportion of 6 to 1 as regards the two first and the last, the difference between the two first being very small. Experiments were also made in France in 1817 to determine the best position of the touch-hole, or vent, of muskets, as regards the charge, the musket being suspended as a pendulum, and the ball being discharged against a ballistic pendulum; but the results, though exhibiting a maximum effect of the ball at a position of the vent corresponding to a distance of one line in front of the bottom of the charge, were so nearly equal to it in several other positions that they would not justify the peculiar selection of any one, unless dictated by convenience in other respects. In artillery it is only necessary to arrange it in a position which will ensure the ready conveyance of fire to the charge, and it is therefore usual to form the vent at an angle of 15° with a vertical from the axis, and terminating at two or three lines in advance of the bottom of the charge—this slight inclination facilitating the breaking of the cartridge by the pricker, which might otherwise slip between the cartridge and the bore.

Howitzers were, according to Senderos, first made in Germany, and subsequently improved by the English and Dutch, but were not used in France till a later period, as they did not appear in the ordinance of 1732, though afterwards adopted and introduced in the celebrated system of Gribeauval. In the British service the 12-pounder howitzer is associated with the 6-pounder gun in the horse artillery, the 24-pounder with the 9-pounder gun in the field batteries, and the 32-pounder may be associated either with the 12-pounder gun in the reserve for positions, or with the 18-pounder guns, should a brass gun of that calibre be adopted in our field service, as it has long been in that of Austria. The 10-inch howitzer (Plate II., fig. 6), and the 8-inch are used in sieges; and the small howitzer (fig. 8), analogous to the Coehorn mortar, for mountain service.

Carronades.—The carronade, invented, or rather improved, by Mr Gascoigne, was, in June 1779, approved as a standard navy-gun, and ten of them were appointed to be added to every ship of war. The carronade is made so short that it is worked with its carriage in the ship's port. (See Plate II., fig. 12.) It is correctly bored; and the shot so nearly fills the calibre that the *least possible* impulse of the powder is lost by the escape of gas between the cylinder and the shot, which last is also thereby more truly directed in its flight. The bottom of the cylinder is terminated by a chamber ending in a hemisphere, to which the end of the cartridge is not liable to stick, and in which the smallest charge of powder envelopes the shot, exhausting upon it nearly the whole of its impelling force. There are sights cast upon the vent and muzzle, to point the gun quickly to an object at 250 and 500 yards distance; and there is a ring cast upon the cascabel, through which the breechin-rope is reeved, the only rope used about these guns. This gun has some advantages over others of *light* construction. It is so extremely light, that the smallest ships can carry almost any weight of shot (the 12-pounder weighing under five hundredweight, and the other calibres in proportion), and that without being attended with the inconveniencies imputed generally to light guns, since it cannot injure its carriage, or jump out of its station in the port upon recoil; and it never becomes heated.

Though the carronade cannot throw its shot to an equal distance with a longer gun, yet, from the adaptation of the shot to its cylinder, with a charge one-twelfth part of the weight of its ball, at very small elevations, it will project its shot to triple the distance at which ships usually engage, with sufficient velocity for the greatest execution, and with all the accuracy in its direction that can be attained with guns of greater lengths; but it has its disadvantages, as for example, by adopting so small a windage, or difference between the diameters of the bore and shot, a windage which would have been impracticable in long guns, it often happened that the shot, although fitted for the long guns, when rusted would not enter the carronades; and the advantage, therefore, consequent on less windage ought not to exist, as the windage of guns and carronades should be the same, being reduced as much as possible, consistent with facility of loading and the use of hot shot; the windage in iron guns need not, indeed, exceed ·15 inch, and Sir Howard Douglas recommends ·14 inch for heavy guns, and ·1 inch or ·11 inch for the 9-pounder downwards. And further, carronades are liable in some positions to fire the rigging or the hammocks either by the flash or by the vent fire, an evil which might be remedied, as Sir Howard Douglas suggests, by giving the 24 and 32-pounder carronades a somewhat longer bore, and adding " something to the flash-rim."

The serious results of the too general adoption of carronades in our ships of war during the last American War on the Lakes, where the Americans obtained such great advantage by the use of their long and heavy guns, fully justify Sir Howard Douglas in his final remarks on this description of ordnance:—" The defects of carronades, and the danger of employing this imperfect ordnance, are now generally felt and admitted; that ordnance, however, rendered important service in its time, for it taught us practically the great value of a reduced windage, the advantages of quick firing, and the powerful effects produced at close quarters by shot of considerable diameter striking a ship's side with moderate velocity;" and these remarks are in some measure applicable, though in a minor degree, to the bored-up guns, in which it has been attempted to obtain increased calibre with diminished weight by *reaming* or boring out guns of originally lesser calibre, as may be seen on inspection of the table of iron ordnance.

The fire of artillery may be divided into two classes—*horizontal* (or at angles near the horizon), and *vertical. Horizontal fire* may be subdivided into *horizontal direct*, and *enfilade. Direct fire* is that used in the field or at sieges, where the gun is discharged directly at the object with a full charge. The *enfilade fire* is that which is not directed against the front of a line but along its prolongation, and the most important form of it is the *ricochet fire*, which is not confined to any particular charge or elevation; each must vary according to the distance and level of the object to be fired at, and particularly the spot on which it is intended it shall make the first bound. Firing *en ricochet* was first invented by Marshal Vauban, at the siege of Ath; and it is principally used in sieges for enfilading the face of a work, by sweeping or bounding along it. *Vertical fire* is that which is thrown from mortars at elevated angles. It was much used at the siege of the citadel of Antwerp in 1832; still more, perhaps, at the late siege and defence of Sevastopol, and became the principal fire at the attack on Sveaborg. Coehorn, who was opposed to Vauban, the author of ricochet fire, was a great advocate of vertical fire, as was also Carnot.

Mortars.—Mortars have succeeded to the ancient bombards, and were at first intended for discharging either one very large ball of stone or a shower of smaller stones. As they are now intended for the projection of shells only, they are designated, not by the weight of the hollow projectile, which is subject to considerable variation, but by its diameter in inches, as 13-inch, 10-inch, 8-inch iron mortars, and 5½-inch and 4⅖-inch brass mortars, of the British Service—the 5½ being also called the " Royal," and the 4⅖ the Coehorn, having been invented by that celebrated engineer, and intended to be used against "sap-heads;" and, indeed, from its portability, to be carried to any point, either in the defences of the place or in the trenches, from which the nearest portions of the approaches, or of the counter-approaches of the enemy could be most efficiently molested. (See Plate II., fig. 11.) The projectile used is the shell or "bombe" of the French, which is thickened at the end next the powder, or at the point of greatest shock, and also about the hole in the shell intended to receive the fuze, or, in the earlier periods of artillery, the match for igniting the bursting powder. It is also provided with loops to facilitate the operation of lifting and placing it in the mortar, in which respect, as well as in having the " culot," or thickening at the bottom, it differs from the " obus," or howitzer shell of the French. The object is twofold; first, as a simple projectile, in which character it acts by the explosion of the bursting powder within, which shatters the shell, and causes its splinters to fly about and act as so many distinct projectiles; and, second, as a mine. In the first case, only that quantity of powder necessary for explosion need be carried, but in the second, the effects depend on the quantity, and hence it is that in a previous article the advantage of very large shells has been strongly urged. The difficulty of constructing mortars for propelling very large shells is undoubtedly very great; but should Mr Mallett succeed with his proposed 36-inch mortar, formed of flat rings bound together by longitudinal bars of wrought iron, the problem will be solved, and the effect of the explosion of 480 pounds of powder, sunk deep into the ground, or penetrating, by the weight—probably 3000 lbs.—of the charged shell through the roof of a magazine or casemate, may readily be conceived. The weight of this mortar and its bed will be 45 tons, and the weight of the heaviest piece when asunder about 15 tons. Mr Mallett is sanguine as to its success. See CANNON for examples of the former use of wrought iron in the manufacture of ordnance in France and Spain, both at remote and recent epochs; the St Etienne Company having submitted an 8-pounder to the most severe trials, and offered, in 1813, to supply the government with 24-pounders of forged iron at the rate of eight per diem.

The mortar is made much shorter than guns, in order to facilitate loading (see Pl. II., fig. 9). It is chambered conically, or on Gomer's construction, so that the shell fits into the chamber, and does away with windage, an advantage which cannot be fully secured by that form of chamber in guns or howitzers fired horizontally, or nearly so. The great Antwerp mortar (fig. 10) had a cylindrical chamber, but it was only partially successful from the defects in the casting of its shells (fig. 17). Senderos states that the art of projecting shells was a happy invention of the latter end of the fifteenth century, and that the difficulty which first attended it, as well as the amount of subsequent improvements, may be judged by the fact that the celebrated artillerist Don Antonio Gonzales, for a long time afterwards, deemed it necessary to set fire to the charge and to the fuze of the shell *separately*, which was called serving it with two fires, a tedious and dangerous process. Until lately it was usual in loading the mortars to lift up the heavy shells by means of handles provided with hooks adapted to seize upon the loops of the shell; and with such weighty masses as the 13-inch shell, the firing could only be slow and gradual, which, after all, must always be the most effective fire. It is now customary to use a "derrick," as in Pl. II. fig. 14, for this purpose; this simple form being that of Sergeant Forrest, Royal Artillery, represented here as in use, but drawn back when not in use. The navy use also mechanical means, and in consequence the firing against Sveaborg was so rapid and continuous that many of the mortars were destroyed by it. Fig. 13, Pl. II., represents also another modern arrangement, namely, the suspension of the large sea mortar, according to the plan of Captain Julius Roberts of the Royal Marine Artillery. The figure explains that by the rotation of the circular platform below, ready means are obtained of pointing the mortar in any direction; and as the mortar revolves round the horizontal axis on firing, it is hoped that the ill effects of recoil will be avoided. In anticipating the results of this arrangement it must be remembered that as the mortar is at an angle of 45°, one half of its momentum will be expended in the direction of recoil, and that the other half must act with a most powerful shock on the axis. Some were tried in the Baltic, but the results are not yet conclusive, though several new mortar-boats are fitting with them.

The moment of bursting is regulated by the fuze fixed into it, as seen in figs. 15, 16, and 17, Pl. II. Fuzes may be either concussive, percussive, or time fuzes. The object of the two first is to cause the shell to burst immediately on striking an object; of the latter, to cause it to burst after a certain time, as determined by the length of the burning composition in the fuze. The concussive fuze is provided with an internal mechanism, so adjusted that though it resists the shock of firing, or even that of a short graze, it shall yield to the shock of impact, the concussion shaking the burning composition into the loaded cavity of the shell, and causing it to explode. The percussion fuze or shell depends for its explosion on a chemical composition of highly explosive character, which bursts the shell at the moment of striking, without being previously ignited. Captain Moorsom's percussion fuze is well known as the British type of this class of fuze, just as Captain Boxer's now is of the time-fuze. The time-fuze is divided into metal and wooden fuzes, the former being used in the navy, and regulated to burn according to the specific use, 20″, 7″, and 2″; the object of percussion or concussion fuzes being to replace especially these short-timed fuzes. The wooden fuze now so admirably constructed by Captain Boxer, and which has so entirely replaced the old fuzes, which required to be *cut* in the field to the proper length, has been figured and explained in art. Artillery. The composition-bore is now made eccentric, so as to allow more thickness for the *two* powder channels. Two rows of holes are made, one into each powder channel, the bottom hole in each row being continued into the composition-bore—each hole of one row, corresponding to the centre of the space between a pair of holes of the other, admitting therefore of subdivision without too much weakening the fuze by bringing the holes of one row close together. By a simple boring-bit a communication between any one hole required for the special length or range, and the composition of the bore, is readily made. The fire, therefore, is communicated from the composition of the fuze, when it has burnt down to this perforation, to the rifle powder in the powder channel: see Artillery for further explanation: and it may be observed that Captain Boxer has since extended the principle, with the necessary modification, to fuzes for mortars.

As mortars are not fired through embrasures but behind epaulements, they are directed by pointing rods, placed in the proper line upon the epaulement; the mortar being brought into line with them by means of a plumb-line held by a gunner standing behind the mortar, on which the line of metal has been marked, the line being placed in the vertical plane passing through the two pointers. Other modes of pointing both guns and mortars will doubtless be hereafter introduced, as the great improvement of artillery practice at long ranges will require the use of telescopic sights, and the introduction of the collimating principle, a fact which has not escaped the attention of artillery officers. The elevation is given by the gunners' quadrant.

Besides the ordinary projectiles, shot and shells, grape and case shot are fired from guns; the first being a number of balls tied or quilted together like a bunch of grapes, and the other a cylindrical tin case filled with balls. They are not calculated for long ranges, but are very destructive at short ranges from 200 to 400 yards either against advancing troops, or fired from the flanking defences of a fortress along the ditch. The Shrapnel shell, or spherical case, is, however, a projectile of still greater value, as it can now be used at almost any range. They can be fired from either gun, howitzer, or mortar; but the object is to fire them from the two first, as, on bursting, the balls which fill them fly forwards with the then velocity of the shell, and being spread by the resistance of the air, deal out destruction equivalent to the action of many muskets in addition to that effected by the splinters of the shell. The practice of putting balls into shells, in addition to the bursting powder, is by no means modern; for Lucar (1588), after explaining the mode of charging shells, and causing them to burst by means of a piece of gunner's match fixed in the match or fuze hole, says—

> "Also you may, if you will, put into the saide hollow baule or pellet certaine square or rounde pieces of lead, or divers shorte pypes of iron like unto *pocked dogges full charged with gunpowder and pellettes*, and fill up the rest of the concavatie with fine gunpowder, and having *annointed* it with turpentine, and roled it in fine gunpowder, shoote it out of a peece of artillery, with a trayne laid to the mouth."

This was in every respect a Shrapnel shell, the mode of firing being consequent upon the early idea that the fuze required to be separately ignited. Shrapnel, however, revived this forgotten projectile, and by giving it an effective form, became its second inventor; as Captain Boxer may now be considered its third, as by the total separation of the balls from the bursting charge, he has done away with the failures by premature bursting consequent on the ignition of the powder by friction against the balls, and rendered it possible to use it with high charges, and for all ranges—the Shrapnel still becoming the true counterpoise to the improved Minié rifle ball, and restoring to artillery its superiority over musketry. Carcasses, or shells filled with a highly inflammable composition which escapes in several directions through the holes (3 or 4) made in them for that purpose, may be fired from mortars or guns: they are also a very old invention.

Rockets.—The history, principle, and possible importance of these projectiles have been fully discussed in art. Artillery, where it was shown that almost every country but that of Congreve, who had first introduced into modern Europe war rockets, had paid great attention to their improvement. In France also they have latterly been much improved; and it has been found possible to use a *short* stick instead of the long one seen in Pl. II., fig. 19. In our own arsenal also, the subject has been taken in hand by Captain Boxer, and mechanical means adopted for insuring precision in the bore, and in the position and form of the vent with every prospect of success. But with every respect for these laudable and skilful efforts, it would be unjust to deny to Mr Hale the merit of having first in this country invented machinery of a most beautiful description for the manufacture of rockets, and for doing away with the stick entirely. Mr Hale's contrivance consists in causing the rocket to rotate on its axis during its flight; and, as in the case of an elongated shot, to move steadily with the point foremost. For this purpose the burning material issues from five orifices made near the neck, obliquely to the axis of the tube, the effect of which is, that the body of the rocket is made to rotate when it is also propelled. Sir Howard Douglas adds to his description of these rockets that the contrivance is very ingenious, and may be expected to produce advantageous results. He, however, adds that, at low angles, they had been found liable to failure, being subject, on a graze, to be deflected from their original direction much more than ordinary rockets, and that unless this cause of failure could be removed they would be of little use against troops in the field, that is to say, in horizontal firing or plane battle-fields. He also observes, that "in other respects also the success of the Hale rocket may be doubted; the stick rocket continues its flight, directed by the stick, after the composition is burnt out; but the Hale rocket loses its directing power as soon as the composition is consumed, because the rotation then ceases, and nothing can be expected from the rocket beyond the distance it has reached when the composition ceases to burn" (which is sooner than in the common rocket, as the composition is more powerful). This objection, however, does not appear well founded, as the object of giving a sufficiently rapid rotation has been effected before the composition *has been burnt out*, and the rotation then continues as in any other rotating projectiles. Mr Hale also promises to realize Congreve's anticipations, by throwing up bundles of rockets hooped together and rotating in mass, to the amount of 400 lbs. It is time that these inventions should be subjected to some decisive trial, and either adopted into the service, or, if found defective, rejected on sound and scientific reasons. The rocket stands of Mr Hale are most ingenious and effective, and strongly contrast with the rude apparatus figured in Pl. III., fig. 13,—the waggon for conveying them being represented in fig. 14.

In respect to the other figures of Pl. III., their names sufficiently explain their object—the two upper figures exhibiting the mode of firing over a high genouillère, or a low barbette, by means of a dwarf traversing platform; and the other of firing over a parapet by means of a high one; and this figure is represented of iron, as generally used in our colonies, and in times of peace—cast iron carriages being inadmissible in actual warfare, as they are so easily injured by shot, and are not repairable.

RANGES AND PENETRATION.

Before closing this article it is necessary to say a few words on these important points in practical gunnery, as, in fact, the main object of the science is to insure that the gunner shall so throw the shot or shells that they shall either strike or explode at some defined point, and also that the shot shall have force sufficient at that point to perform the work required from it,—as, for example, if the residual velocity of a Shrapnell shell were almost 0 at the time of its explosion, the balls would fall almost harmless on the ground, just as the balls would do when fired from a mortar, as proposed by Carnot (see FORTIFICATION). The trajectory of a projectile would be *in vacuo*, as before stated, a parabola, and therefore easy of computation, supposing the initial velocity known. As, however, all military projectiles are projected in the air, and are resisted in their motion by that elastic fluid, the trajectory is not a parabola; and that simple theory can only in rare cases be applied to practice, or in cases where the velocity is less than 300 feet per second. It is, however, necessary for the clear understanding of the phenomena of projectiles to know at least the formulæ which represent the results of the parabolic theory, and they are therefore given as follows:—

Let V be the initial velocity in the direction of projection;
ϕ the angle of projection above the horizontal plane;
x and y the horizontal and vertical co-ordinates to the curve of the trajectory at any point P, estimated from the commencement of the curve, or point of departure as the origin;
t the time of flight to that point, v the horizontal velocity at it, and v' the velocity in a vertical direction;
θ the angle of inclination of the tangent at that point with the horizon;
X the whole horizontal range, or horizontal co-ordinate, when y becomes again 0 as it was on departure;
Y the greatest height of ascent, or when y is a maximum;
T the whole time of flight;
H the height, falling from which a body would acquire a velocity equal to V.

$x = \mathrm{V}t \cos\phi,\ y = x \tan\phi - \dfrac{x^2}{4\,\mathrm{H}\cos^2\phi}$;

$t = \dfrac{x}{\mathrm{V}\cos\phi}$; $\mathrm{V}^2 = 2\,g\mathrm{H}$, or $\mathrm{V} = \sqrt{2\,g\mathrm{H}}$, g being the velocity acquired in falling through 1 second by the force of gravity (32·2 feet nearly).

$\mathrm{X} = 4\,\mathrm{H}\sin\phi\cos\phi$; $\mathrm{Y} = \mathrm{H}\sin^2\phi$;

and as $v = \dfrac{dx}{dt} = \mathrm{V}\cos\phi$, which is constant, it is evident that v, or the horizontal velocity at every point of the curve is constant; $v' = \mathrm{V}\sin\phi - gt$, and the velocity in the direction of the curve $= \sqrt{v^2 + (v')^2} = \sqrt{\mathrm{V}^2 - 2\,\mathrm{V}gt\sin\phi + g^2t^2}$, or $= \dfrac{\mathrm{V}\cos\phi}{\cos\theta}$.

$\mathrm{T} = \dfrac{4\,\mathrm{H}\sin\phi}{\mathrm{V}}$, or $= \sin\phi\sqrt{\dfrac{8\,\mathrm{H}}{g}}$. Since $\cos\phi\sin\phi$ is the same for any given angle and its complement, it is evident that there are two angles of elevation, ϕ and $90° - \phi$, which with the same initial velocity give the same range. The elevation remaining the same, the horizontal ranges being $= 4\,\mathrm{H}\sin\varphi\cos\varphi = 2\,\mathrm{H}\sin 2\,\varphi$, it is evident that the initial velocities, or H, remaining the same, those ranges vary with $\sin 2\,\varphi$, and such range is therefore the greatest when $\sin 2\,\varphi$ is greatest, or when φ is 45°.

As the influence of the resistance of the air in modifying the motions of a projectile is less in proportion as the projectiles are greater, the true range of a musket, as compared to the theoretic, being 1 to 18, with field and siege guns the range *in vacuo* exceeds that in the air, as 3·05, 2·80, 2·69, 2·47 to 1 respectively, the proportion diminishing as the projectiles become greater; so that it might be reasonably anticipated, that with still heavier and larger projectiles, whether shot or shells, the approximation of the real range to the theoretical one, on the parabolic theory, would be still closer; but unfortunately there is here a difficulty, as the initial velocity of shells fired from mortars at high angles has not yet been determined experimentally, and the ranges therefore cannot be satisfactorily calculated. Supposing, however, the ranges observed, the times of flight may be calculated, and compared with the same times observed, and this has been done in France with the 8½ and 11-inch mortars. In the 8½ inch, fired at 45°, the ranges being 375, 688, 1254, 1960 yards respectively (the charges varying from ½ lb. to 2⅙ lbs.), the differences in time were 1″·4, 1″·6, 0″·7, 1″·6. In the 11-inch fired at the same angle, the ranges being 505, 803, 1238, 1701, 1922 yards, and the charges varying from 1 lb. to 3½ lbs., the differences in time are 1″·3, 1″·5, 1″·8, 2″·2, 4″·1, or between $\frac{1}{10}$th and an $\frac{1}{8}$th of the whole time, excepting in the last case, where it amounts to about $\frac{1}{6}$th. When fired at an angle of 30°, the difference in the times vary from $\frac{1}{13}$th to $\frac{1}{7}$th of the whole times, the time observed always exceeding the time calculated; the retardation being due to the resistance of the air. In the case, therefore, of shells, the movement approximates much more closely to the parabolic motions than in either cannon or musket balls. The velocity indeed of the 11-inch deduced from the range and theoretic time, would be about 435 feet per second; and Griffiths gives 500 feet as the velocity of the 10-inch fired with 3 lbs. charge.

These examples taken from Didion, prove that a limited use may be made of the parabolic theory in respect to the motion of shells when fired with such moderate velocities; but it is totally inapplicable to the case of guns; and the labours of the most able mathematicians have been applied to the solution of the difficult questions involved in the determination of the trajectory of the projectile in the air, when moving with such great velocities.

For elevations not exceeding 10°, Poisson's formula is—

$$y=x \tan \varphi - \frac{1}{8\,k^2h \cos^2 \varphi}\,(e^{2kx} - 2\,kx - 1);$$

x and y being the horizontal and vertical ordinates at any point of the curve, the origin being in the axis of the bore at the muzzle of the gun, ϕ the angular elevation of the gun, h the height due to the initial velocity of the shot, r its semi-diameter, $e=2·71828$ the base of the Napierian logarithms, and $k=\frac{q\delta}{r\delta}$, the co-efficient of the square of the velocity in the expression for the retardative force of the resistance of the air, δ being the density of the air or medium, δ' that of the shot, and q a fraction which must be determined by experiment, and which, though doubtful, may be assumed as 0·225. It can be simplified for small elevations and short ranges, by developing e^{2kx} in series, neglecting all above the fourth term, and substituting the result, when the formula becomes—

$$y=x \tan \varphi - \frac{x^2}{4\,h \cos^2 \varphi}\,(\tfrac{2}{3}\,kx+1);\ \text{or}$$

$$y=x \tan \varphi - \frac{gx^2}{2\,V^2 \cos^2 \varphi}\,(\tfrac{2}{3}\,kx+1);$$

V being the initial velocity.

Didion has given other formulæ of considerable simplicity, but as they require for their practical application the use of the tables of values of several co-efficients, which he has calculated and published in his admirable treatise already so frequently referred to, they will be better studied in that work.

In ranges corresponding to 1° of elevation, which in the larger natures would give about 700 yards, the cosine may be taken as equal to radius, or 1; and hence, as Captain Boxer points out, the equation becomes—

$$y=x \tan \varphi - \frac{x^2}{4\,h}\,(\tfrac{2}{3}\,kx+1).$$

The time of describing any portion of the trajectory is expressed by the equation $t=\frac{1}{k\sqrt{2\,gh} \cos \varphi}\,(e^{kx} - 1)$; and when X, or the *whole range*, is substituted for x, $t=T$, the whole time of flight.

Sir Howard Douglas also gives an empirical formula from the *Aide Mémoire Navale* for deducing the ranges of shot from the maximum range determined by experiment, the elevation being between 10° and 30°.

Let R represent the range at 30°, considered the maximum, then $X=R\,(\sin 3\,\phi)^{\frac{2}{3}}$.

It will be observed that in all these formulæ, and it must be so in every formula, everything depends on the accurate determination of the initial velocity, and a correct knowledge of the nature and amount of resistance opposed by the air to the motion of the projectile. The mode of determining the former experimentally has been already pointed out; but as it may be necessary to determine by calculation the initial velocity of one ball from the experimentally determined velocity of another, Piobert has proposed the following empirical formula:—

$$V=v\,\frac{\sqrt{\log\left(1+\frac{p}{W}\right)}}{\sqrt{\log\left(1+\frac{p}{w}\right)}};$$

V being the initial velocity sought of the ball whose weight is W, and v the experimentally determined velocity of the ball whose weight is w, the charge p being the same in each case. Major Mordecai, of the United States army, has found this rule to agree with his experiments when the charges do not exceed one-third of the weight of the ball, and the gun is at least 16 calibres in length, but does not consider it sufficiently accurate for higher charges. Taking $\frac{v}{\sqrt{\log\left(1+\frac{p}{w}\right)}}=M$ as a factor, Major Mordecai found that with a 32-pounder, the charge being one-third, and the windage 0·16 inch, M = 5200; with a 24-pounder, the charge being one-third, and the windage 0·14, M = 5400.

A British empirical formula is $V=1600\sqrt{\frac{ap}{w}}$; p being the charge, w the weight of the ball, and a a co-efficient depending on experiment, and varying, according to Hutton, with the length of the gun between 2·1 and 2·5, as also with the ratio of the weight of the charge to that of the shot. General Millar, by experiments in 1817, has also shown that it increases as the windages decrease, being 2·8 with a windage of 0·202 of an inch, and 3·55 with a windage of 0·075; whilst from experiments made at Deal in 1839, and on board the "Excellent" from 1837 to 1847, the mean values of a are 3·2 for a windage of 0·233; 3·4 for 0·2; 3·6 for 0·175; 4·4 for 0·125; and 5· for 0·09; and when the windage is 0, a becomes 6·66. The velocity, therefore, with a windage of only 0·125 being to that without windage as 1 to 1·23, the loss from that small windage being one-fifth nearly of the whole velocity, a convincing proof of the propriety of reducing the windage of all balls to that quantity which will admit their ready introduction, allow for the chance of rust, and for their expansion when used as hot shot, which in the largest balls is about $\frac{1}{70}$th of the calibre, or in an 8-inch shot, 0·114 of an inch; so that 0·15, proposed by Sir H. Douglas, would be amply sufficient. With carronades, in which the windage varied from 0·061 to 0·078, the mean value of a was 4·5.

The initial velocities and ranges being known by experiment, the co-efficient for the resistance of the air, may be obtained from the equation $k=\frac{3}{2}\cdot\frac{V^2 \sin 2\ \ -gx}{gx^2}$.

The velocity at known distances from the gun may be represented by $v=\frac{V}{e^{kx}}=Ve^{-kx}$; or, according to the formula of the French School at Metz, as quoted by Sir H. Douglas: $v=\frac{V}{(1+aV)\,e\gamma^{x}-aV}$. v the velocity at the point sought, V the initial velocity, and x the distance, or horizontal co-ordinate, being expressed in English feet, $a=0·0007$; γ varying with the nature of the shot, but in a 32-pounder is equal to 0·0001034; this formula being founded on the assumption that the resistance of the air is partly proportional to the square, and partly to the cube of the velocity.

The penetration of shot, the velocity at the point of contact having been determined by one or other of the above formulæ, may be thus represented: $P = \frac{2v^2r\delta}{3\rho g}$; P being the depth penetrated, v the velocity of the shot at the instant of striking, r the semi-diameter, δ the density of the shot, and $g = 32{\cdot}2$ feet, the force of gravity; ρ a co-efficient of resistance, to be determined by experiment on various substances.

When the resisting substance is the same, P varies as $rv^2\delta$, or when the density of the shot is the same as rv^2; the penetration in this case then varying as the diameter of the shot and the square of the velocity. From Poncelot's hypothesis that the resistance of a material struck by a shot is proportional to the square of the shot's diameter; and from the Gavre experiments, P, in respect to value, may be represented by this formula (Sir H. Douglas having modified it so as to represent P in English feet):—

$P = 4{\cdot}612\ rd \log\left\{1 + \frac{v^2}{1076696}\right\}$; d representing the specific gravity of the shot; water being 1. For firm earth this may be multiplied by 1·64; for sand and gravel, by 1·3; for loose earth, by 3·21; for sound masonry, by 0·41. In the previous formula the specific gravity may be also substituted for the density when it becomes $P = \frac{2v^2rd}{3\rho g^2}$, as $d = g\delta$.

Terminal Velocity.—When a body descends in air from a state of rest, its velocity increases for a time by the action of gravity upon it; but the resistance of the air *increases* as the velocity increases, and hence it must at length become equal to the accelerative force of gravity which is *constant*, after which the body will move uniformly with the velocity acquired, or with the *terminal velocity*, making therefore, $kv^2 = g$, $v^2 = \frac{r\delta g^2}{q\delta}$; or $v = \sqrt{\frac{r\delta g}{q\delta}}$; and with shells $v \sqrt{\frac{r\delta g}{1{\cdot}42qd}}$; the weight of a solid shot to that of a shell being as 1·42 to 1; q being $= 0{\cdot}225$, as before stated.

As the terminal velocities vary with the square roots of the diameter of the shot, the density being the same, and the terminal velocity of a shot 2 inches in diameter, as deduced from Hutton's tables, being 248 feet per second; that of a 24-pounder is 415·53, or

$$\sqrt{2} : \sqrt{5{\cdot}612} :: 248 : 415{\cdot}53;$$

and that of a shell of the same diameter would be

$$\frac{415{\cdot}53}{\sqrt{1{\cdot}42}} = 415{\cdot}53 \times 0{\cdot}8392 = 348{\cdot}71.$$

General Duchemin has given the following formulæ for the loss of velocity by windage: V being the initial velocity, V^- the velocity lost, s the diameter of the vent, C the calibre of the gun, C′ the calibre of the shot, $C - C' = C^-$ the windage, $\alpha = 3{\cdot}5$, a constant, and $\beta = 0^m{\cdot}182857$, a constant also of the same species as C and C′:—

$$V^- = V\left\{1 - \left(\frac{s}{\alpha C}\right)^{\frac{1}{2}} - \left(\frac{C^-}{\beta}\right)^{\frac{1}{2}}.\right.$$

In using this formula for English feet, it is only necessary to represent C, s, and C^- in decimals of a foot, and to make $\beta = 0{\cdot}599955$; or if these terms are given in inches, to make $\beta = 7{\cdot}199458$.

Duchemin has also given the following empirical formula for the charge of greatest effect—

$$M = \frac{34^{gr}{\cdot}0423}{(0^m{\cdot}0513)^3} C^3 \sqrt{a\delta}\ ; \quad a \text{ being} = \frac{b}{C}$$

or the number of times the calibre is contained in the length of the bore, and C and δ as before. This formula may be used for the charge in English weights and measures by using $0'{\cdot}1683$, or $2''{\cdot}0198$ instead of $0^m{\cdot}0513$, according as C is represented by a decimal of a foot, or in inches—and replacing $34^{gr}{\cdot}0423$ by its value 75·0973 in English pounds.

Many other usual formulæ might be extracted from various authors, but those given will be sufficient for the reader, and indeed for most purposes of general study. Those who desire to obtain a still more accurate knowledge of the dynamical theory of projectiles, should turn to the admirable work of Didion; and those who wish to know still more fully its bearing on the purposes of war, whether in our marine or land armaments, should read the excellent work of Sir Howard Douglas, now arrived at its third edition, which is unquestionably the best book on the subject in our language. The work of Captain Boxer (of which the first part only has as yet been published) preparing as a course book for the Royal Military Academy, is even now deserving a careful perusal, and will, when finished, render references to writers on foreign artillery unnecessary. Sir Howard Douglas was originally an officer of artillery, and has ever since retained a feeling for his first service, which has led him to apply the powers of a highly scientific mind towards its improvement. Captain Boxer is an officer of artillery, and now occupies his right position as a man of science at the head of the Royal Laboratory: let, indeed, the system now maintained by Lord Panmure of appointing to such posts only men of science be continued, and the Royal Artillery will soon supply officers fitted to fill the posts of its manufacturing establishments with honour, and thereby to advance the interests of their country.

Of other works I need only name the excellent Spanish treatise of Senderos, so often quoted in this essay.

Valuable, however, as the investigations of science always are, and essential also as they must be for perfecting the theory, and thereby also the practice of gunnery, it is manifest that the calculation of formulæ could never be undertaken in the field; and hence that the results of the labours of the calculator must be placed in such a form as to be readily consulted at the moment they are required. Tables, therefore, have been formed for that purpose, such as those of the French, and those of the English service, which close this article. The latter, for heavy guns, have been carefully digested by Lieutenant-Colonel Lefroy, R.A., from the results of both land and sea-practice; the sea being that of the "Excellent," the instructional gunnery-ship at Portsmouth. The tables for field-guns are those of Col. Burn, R.A., as printed and published by him on cards for the general and convenient use of the members of his profession. They represent, therefore, our *practical* knowledge up to the present day; but they must not be considered as results finally and fully determined. Far from this, as every day ought to do something for their improvement, and will do so when the important establishment at Shoebury-Ness has been rendered fully efficient in all its details. It is bad economy to stint such an establishment in anything necessary for its efficiency; or by denying those instruments which have become familiar in foreign arsenals, to make it only a school of drill, instead of an important element in the great school of instruction, which, beginning at Woolwich, should end here.

It has been already remarked that the electro-magnetic cronograph for determining the time of flight of a projectile through various points of its trajectory, was submitted by Wheatstone to the select committee at Woolwich; but as yet it has not been applied at Shoebury-Ness. It is true that this mode of determining the time of flight has not always succeeded; but the causes of failure do not appear difficult of removal; and a government establishment is assuredly the right place for experiment.

This article, then, is closed with a fervent wish that the spirit of inquiry, which is beginning to spread over our artillery, will be fostered, and the thirst for professional knowledge, which now animates so many of its officers, will be encouraged and rewarded; and that ere long our artillery will be as distinguished for its science, as it has always been for its discipline and valour.

ENGLISH TABLES OF RANGES.

Tables of Ranges of Iron Ordnance. From the Handbook of Field Service of Lieut.-Colonel J. H. Lefroy, F.R.S., *Royal Artillery.*

IRON ORDNANCE.

Remarks.—The ranges for the 10-inch gun are the mean of the two scales of Colonel Burn, one 8 feet, the other 5 feet above the plane. The same data must be nearly correct for the shell of 87·5 lbs. The times are interpolated from the "Excellent's" Tables, 1852; which, however, allow about 0·5° greater elevation for the same ranges. Height of gun above plane B 6·5 feet.—"Excellent" not stated.

The ranges for the 8-inch gun, hollow shot of 47 lbs. are interpolated by projection, from the mean of 137 rounds fired at Shoebury Ness, 1850–2; for the sea service, hollow shot of 56 lbs. and shell of 50 lbs.; the first, with each charge, is from Colonel Burn, the second from the "Excellent."

For the Shrapnel shell, from Colonel Burn.

Ranges of 68, 56, and 42-Pounders.

The data above, printed in ordinary type, are from Lieutenant-Colonel Burn's Cards; those in darker type, from the Tables of the "Excellent." The differences, like those shown in the Tables of the 8-inch gun, deserve notice, but are not attributable to a difference in the height of the plane, which, when given, is from 5 feet to 8 feet. A similar discrepancy between the naval and land service tables in the French service led to an investigation of the subject, by a committee, at Gavre, 1843, which came to the practical conclusion, that the mean deviations at sea do not differ *cet. par.* from those on land (Douglas, 3d edit., 146). Officers will readily decide, from their own experience, which data, under their particular circumstances, are to be relied on.

GUNPOWDER.

THE invention of gunpowder is popularly ascribed to Barthold Schwartz, a German monk and alchemist; and the date of the discovery is further supposed to have been in 1320. The prior claims of our countryman Roger Bacon—whatever they be—are, however, unquestionable, as this substance is described in his writings about the year 1270, or fifty years before the time of the supposed discovery of Schwartz. But even Bacon has as little title to this invention as his supposed rival; nor, indeed, when we examine his own description of this then wonderful compound, do we perceive that he makes any claim to have been the discoverer. On the contrary, he quotes it as a well-known substance, in common use all over the world for making squibs to amuse children. So pertinacious are vulgar errors. The passage in Bacon stands as follows:—"Ex hoc ludicro puerili, quod fit in multis mundi partibus, scilicet, ut instrumento facto ad quantitatem pollicis humani, ex violentia salis qui salpetræ vocatur, tam horribilis sonus nascitur" (this is the description of a parchment cracker) "in ruptura tam modicæ pergamenæ, quod fortis tonitru rugitum et coruscationem maximam sui luminis jubar excedit."[1] Thus the claim is shifted without difficulty from Bacon, and, as Dutens thinks he can show, is removed to Magnus Græcus, whose manuscript he quotes, and from which he presumes that Bacon derived the invention; although, by his own showing, Bacon need not have consulted an obscure writing for an invention of general notoriety. The title of the manuscript in question is as follows:—"Incipit *Liber Ignium* a Marco Græco perscriptus, cujus virtus et efficacia est ad comburendum hostes, tam in mari quam in terra;" so that even the military uses of gunpowder were then known. In the same manuscript are contained directions for making a rocket, which we do not quote on account of its length; but it is such as to prove that the nature of this fire-work was understood. It is even remarkable that he recommends particularly the charcoal of willow wood, which in modern times has been found to be amongst the best for making gunpowder.

Thus far, although we have not fixed the date of the invention, we have carried it, not only beyond Bacon, but even beyond his supposed predecessor; as he himself does not pretend to be the inventor, but the compiler, of a *Liber Ignium*, or treatise on Pyrotechny. If, in attempting to ascend still higher, the evidence becomes more rare and more obscure, there are still insuperable facts to prove that its antiquity is far greater, however impossible it may be to approximate to the date of the invention, far less to assign that which seems buried amongst the obscurities of oriental learning. The question of gunpowder, as applied to artillery, is a separate one; but there is abundant reason to believe that this compound was not only used in some form or other as an explosive and combustible substance, but was even applied to military purposes; it may be, in the shape of rockets or other fire-works, which, for objects of amusement at least, have been familiar to the Chinese beyond all record.

The earliest date to which we can refer the knowledge of gunpowder, in defect of a sufficiently remote acquaintance with oriental history, is 355 before Christ; although, from the very nature of this evidence, it follows that it was then not only known to the eastern nations, but that it must have long been so; since, even at that early period, it was applied to warlike purposes. In the code of Hindu laws, indeed, where it is mentioned, it is referred to a period which oriental antiquaries have considered as coincident with the time of Moses. But the evidence to which we more particularly allude is found in a passage of the Life of Apollonius Tyanæus, by Philostratus; the purport of which is, that Alexander was unwilling to attack the Oxydracæ—who lived between the Hyphasis and the Ganges—because they were under the care of the gods, and overthrew their enemies with thunder and lightning, which they shot from their walls. The same tale is told of the repulses experienced in this country by Hercules and Bacchus.

The next of these early dates, in which also our evidence is imperfect, is 212 before Christ; but the establishment of the truth of the last would render this one more credible. In the defence of Syracuse by Archimedes, Vitruvius relates that one of his engines threw large stones with a great noise; a description which does not apply to any of the mechanical artillery of the ancients. On a notice so superficial, we must not, however, lay too much stress; but it would appear that the earliest knowledge of gunpowder is capable of being traced from the East, through the intervention of the Arabs, and thence into Europe; and, indeed, the military use of rockets in the armies of India ascends to a period beyond record.

Of the earliest period at which it was known in China, we have, in defect of their own evidence, the testimony of Uffano, an Italian author, who affirms that not only gunpowder, but ordnance, was in use in that nation in the year 85 of our era; and that cannon were, in his day, remaining from the most ancient times, in some of the maritime provinces, made both of iron and brass. Hence some writers presume that the Chinese communicated the invention to the Indians; whilst it has also been said, but on no sufficient authority, that they themselves received it from Tartary—a nation respecting which we know little or nothing, and in which we should not be inclined to look for an early acquaintance with the arts. This, however, refers to a date so late as 917; so that, if there is any dependence to be placed on the Indian and Chinese hypothesis, the Tartars must themselves have borrowed the invention from those to whom they are said to have lent it.

There is after this a long blank; and the first author on the subject that we have discovered is in 1249, twenty years before the date of Bacon's narrative. This is an Arabic writer, in the Escurial collection, who is translated by Casiri. His description is such that it may apply both to rockets and to shells. In the former case it only proves the knowledge of the detonating compound; the latter, were it proved, would show that they were also acquainted with the use of ordnance, although it is not impossible but that such projectiles might have been thrown by mechanical artillery.

As the invention of gunpowder has been popularly attributed to Bacon and to Schwartz, so the use of ordnance has been referred to the time of the field of Cressy, or 1346. To pass over the Chinese hypothesis on this part of the subject, we shall find that cannon were known at least as early as 1312. This we derive from the source quoted by Casiri; from Arabian writers, who describe the use of ordnance in 1312 and 1323; whilst, if Barbour is to be trusted, Edward III. was also provided with some pieces of artillery in 1327; and Père Daniel asserts that cannon were known to the

---

[1] Bacon, who was apparently afraid of revealing too much, conceals one of the ingredients under the veil of an anagram. He writes—"Sed tamen salis petræ *luru mone cap ubre*, et sulphuris, et sic facies tonitrum et coruscationem, si scias artificium." The italics are unmeaning in their present form, but the letters may be so combined as to make *carbonum pulvere*, or powdered charcoal. The passage may then be translated thus:—"But, nevertheless, take of saltpetre, with pounded charcoal and sulphur, and thus you will make thunder and lightning, if you know the mode of preparing them."

Gunpowder.

French in 1338. We need not carry this discussion lower; though, in favour of the oriental origin of this invention, we would still remark, that artillery was much in use in the Mediterranean when it was still but little used elsewhere; as by the Venetians against Genoa in 1380, and by Alphonso XI. in his wars against the Moors.

In a work, published at Paris in 1845, entitled *Du Feu Grégeois, des Feux de Guerre, et des Origines de la Poudre à Canon*, the authors (MM. Reinaud and Favé) endeavour to connect gunpowder with the celebrated Greek fire which the Greeks of the Lower Empire and the Arabs used at the beginning of the mediæval epoch; and they even endeavour to establish a Chinese origin for the Greek fire. So long back as 200 years B.C., the Chinese appear to have used various incendiary compositions under the names of "devouring fire," "earth thunder," &c. Now, the Greek fire was introduced from the East into Constantinople in the year 673, and it greatly assisted the Greeks of the Lower Empire in gaining many battles. Its composition was kept secret under the severest penalties, but the engines of war with which it was used are described by contemporary writers, and these are said so closely to resemble the Chinese engines, as to leave no doubt of their common origin. In the treatise of Marcus Græcus, which our authors ascribe to some period between the ninth and twelfth centuries, the composition of a combustible compound as used by the Greeks is given, and tends also to confirm the common origin. The historians of the Crusades refer to the terror experienced by the Christians at the incendiary resources of the Arabs, but it is only the Western historians who speak of the Greek fire; while, in a manuscript discovered by M. Reinaud, containing a treatise on Pyrotechny by one Hassan-Abramman, the author speaks of Chinese fires, or employs Chinese epithets to them. MM. Reinaud and Favé state that, from the eighth to the ninth centuries of the Christian era, the Arabs had frequent intercourse with the Chinese. They admit the difficulty of ascertaining when fire-arms were first used in Western Europe. Either the Crusaders may have learnt the use of them from the Eastern Arabs, or the secret of the Greek fire may have been revealed at the taking of Constantinople in 1204; but there is no doubt, they assert, that Albertus Magnus and Roger Bacon obtained their information from the earlier work of Marcus Græcus, and hence these two writers have been wrongly regarded as the inventors of gunpowder. Roger Bacon hints that religious scruples rather than ignorance prevented the nations of Eastern Europe from generally adopting the use of the Greek fire. These scruples appear, however, gradually to have yielded. Froissart mentions it, and later writers refer to it, either under the name of Greek fire, or by some analogous name, and the substance referred to generally agrees with the recipe given by Marcus Græcus; hence our authors conclude that the art of making the Greek fire has never been lost, but has simply been superseded by better contrivances. Favé thinks that the reason why gunpowder was not known as a means of propulsion, arose from the impurity of the ingredients. He has no doubt that saltpetre, sulphur, charcoal, and other matters, were employed for deflagration, and, being impure or badly mixed, the compound would burn rather than explode. He conjectures that gunpowder, as such, was first used in the western parts of Europe, especially in Hungary and the neighbouring countries. In a Latin MS. in the Imperial Library at Paris (No. 7239) the use of powder in mines is referred to. This MS. was brought from Constantinople in 1687, and contains a treatise on the implements of war, and a map evidently constructed between 1395 and 1396, and M. Favé assumes the MS. to be of the same date.

Composition of Gunpowder.

The present composition of the Chinese gunpowder corresponds so nearly with our own, that the difference is nearly insensible; but whether it had arrived at that degree of perfection in their ancient periods, we have no means of knowing. Neither can we judge of its nature and power as known to the Arabs. But in our own country it was late in arriving at its present state of perfection; nor do the various proportions given by one of our earliest writers on the subject argue much in favour of their chemical knowledge. Peter Whitehorne, who wrote in 1573, gives numerous proportions, without seeming to be well aware of their respective values; and, respecting some of them, it is easy to see that they were scarcely fit for squibs, much less for the purpose of projecting shot. Such is nitre, sulphur, charcoal, equal parts; whilst, in the very opposite extreme, we have nitre 12 parts, sulphur and charcoal, of each 3 parts; and, still worse, nitre 27 to 3 of the other two ingredients; or nitre 48 parts, with 7 of sulphur and 3 of charcoal. Here, such as these compositions are, want of experience can scarcely be pleaded, as they are not better than those given by Nye in 1380. In France also, the composition, at no very remote period, was—nitre 50, sulphur 16, charcoal 34; from which it varied to, nitre 67, sulphur 13, charcoal 20; and to nitre 84, sulphur 8, charcoal 8; these differences being supposed to be necessary for the larger cannon, and the smaller progressively, the last being their musket powder.

But as we cannot afford space to describe the gradual progress of improvement in the composition of gunpowder, we will state the proportions at present in use in different nations. They do not materially differ from each other, although it is unquestionable that they are not all of equal power.

	Nitre.	Sulphur.	Charcoal.
Royal Mills at Waltham Abbey	75	10	15

Sweden	76	9	15
Switzerland, round powder	76	10	14
Chinese	75·7	9·9	14·4

Without any knowledge of the law of definite proportions, and even before that law was known to exist, each nation had experimentally hit upon nearly the best proportions of the three ingredients, namely, 1 equivalent of nitre, 1 of sulphur, and 3 of charcoal; or 75 per cent. of nitre, 11·77 of sulphur, and 13·23 of charcoal. In practice the proportions used for the manufacture of 100 lbs. of gunpowder are—saltpetre $77\frac{1}{2}$ lbs., sulphur $10\frac{1}{2}$ lbs., charcoal 16 lbs. = 104 lbs., the extra 4 lbs. being allowed for waste.

The proportions in the *commercial* gunpowder of England vary indefinitely, according to the views of the manufacturer respecting the markets, the price, and other matters. Cheapness being the leading object where it is only made for sale, and the nitre being the only expensive article, the proportion of this is diminished, and those of the other two ingredients increased. The worst is made for the Guinea trade; and, if we are not misinformed, that for the Canada trade is nearly as bad, whilst the next upwards in the scale is that sold to Turkey. We have never met with any specimen in which there was less than 62 of nitre; but we have reason to believe that some of the inferior kinds do not contain more than 50. For the use of miners it is also made with a low proportion of nitre, producing advantages in mining not intended by the makers, whose only object is to manufacture a cheap article. But the proportions of all the commercial powders are very inconstant, even when furnished *bonâ fide* to the government.

It is not for want of experiments if greater uniformity has not been attained in these compositions, and if all adhere to their own. Baptista Porta was one of the first who made accurate investigations on this subject; and, as long ago as the sixteenth century, he fixed on the proportions now used in France. Beaumé fixed on 80 of nitre, 5 of sulphur, and 15 of charcoal; while Morveau and the Committee of Public Safety assumed three proportions, viz., 76, 77, and 80 of nitre, 9, 7, and 5 of sulphur, and 15, 17, and 15 of charcoal respectively. Chaptal gives the proportions 77, 9, and 14; and Proust 78, 9, and 13. It is easy to account for these differences of opinion, when we recollect the numerous accessary circumstances which modify or vitiate the results obtained from practice. With the very same power it is scarcely possible to procure uniform results, as is well known to artillerists; and hence, from practice alone, unless after an enormous number of trials, no certain conclusions can be drawn. It will, indeed, appear that, under various proportions, the effects may really be the same; because, as the force of powder depends partly on the quantity of gas generated, and partly on the heat to which it is raised, any deficiency on the one hand may be compensated by an increase on the other. Thus, as the greater quantity of gas is produced by the largest proportion of charcoal, the greater heat is caused by augmenting that of the sulphur. In all the trials that have been made in this country, no reason has been found for varying from the proportion 75 nitre, 10 sulphur, and 15 charcoal; and the same is used for arms of all calibres, the only difference for the respective arms being made in the sizes of the grains.

It is proper, on this subject, to state, that whilst the explosive power depends fundamentally on the quantity of gas that is permanently generated, that gas is almost entirely produced by the combustion of the charcoal; the nitre being the cause of that combustion, and furnishing one part of the generated gas from its decomposed acid, as it does the other by converting the charcoal into carbonic acid. Were nothing else required, therefore, to produce the effect, the best powder would consist of nitre and charcoal alone, as the sulphur consumes a considerable part of the oxygen of the nitric acid, without adding anything to the permanently elastic gas. But as there are two other important elements in this problem, namely, the rapidity of the inflammation and the heat, the sulphur becomes an indispensable ingredient; whilst, by expanding the gas at the moment of explosion, it more than compensates for the diminution of permanent bulk which it causes. Perhaps, on this compound view of the subject, M. Beaumé's composition is really the best, abstractedly considered, as the nitre is sufficient to burn the whole of the sulphur and the charcoal also, and as both the degree of heat and the quantity of gas seem to be best balanced for the intended effect. But a composition of this accurate nature requires equal accuracy of mixture and manufacture; and as that is scarcely attainable on the great scale, it is found better so to increase the sulphur and charcoal as to ensure the total decomposition of the nitre, this being further an object of economy.

Sportsmen, as well as artillerists, ought to know that the fouling of their barrels after firing is in a direct ratio of the weakness and badness of their powder; and this effect is most completely obviated by using M. Beaumé's, or any similar mixture. Not only does the feebleness of such powder prevent the barrel from being swept clean at the explosion, but as the foulness consists chiefly in a mixture of the carbonate and sulphate of potash with charcoal, that becomes necessarily greatest wherever the nitre is reduced in quantity for the purpose of introducing the cheaper ingredients. The analysis of powder, at least as far as that ingredient is concerned, is so easily made, that every one who feels an interest in his success as a sportsman should examine what he uses, as the very worst mixture can be rendered beautiful to the eye by a minute grain and a high polish.

The British government use but one proportion for all services. As far as artillery and musketry are concerned, we do not consider this as of much moment; or that any material object would be obtained by using different ones proportioned to the respective calibres. But we consider that they commit a great error in adopting the same for the *mining* service; and that some of the failures caused in our wars, in attempting to blow up works or demolish bridges, have been produced by the very excellence of the powder—in short, by its too great strength. To take the case of common blast-mining as a simple one, and to put the extreme case of all: If it be attempted to spring a rock by the powder of chlorate of potash, either the plug will be blown out, or a very narrow space round the mine will be broken. With the best musket or cannon powder the same effects, but in a less degree, follow. Here the miners' powder, which seldom contains as much as sixty per cent. of saltpetre is effectual; and, what is more, it is rendered still more active by being damp from careless keeping, or from remaining some time in the mine before it is fired. Mathematicians will immediately see the solution of this apparent incongruity, by recollecting that the element of time is an ingredient in the problem. With too great a velocity the parts of the general mass nearest to the acting force are disintegrated; so that not only is the force expended in this act, but the gas thus escapes from the opening. With a power acting more slowly, the whole mass, or a much larger one at least than in the first case, is moved; and thus the rock is widely shaken, although not blown into the air. It will be found practically, that the further the fragments are dispersed, the less is the effect; and thus the mine which is most dangerous to the workmen is also the least efficacious.

It is from this variation respecting the power of gunpowder, hitherto unattended to, from confounding impulse and pressure, to which at least it bears a certain relation, that so many different opinions have been entertained respecting the force of powder in particular cases. Hence also have arisen various projects for increasing its efficacy; amongst which quicklime has been repeatedly recommended. In mining it does actually increase the effect, though not the force. On the contrary, it diminishes the force; and it is from that very cause that it is more effectual in mining or shaking a rock. The same object can be obtained by a mixture of saw-dust; but it must also be remembered that this will not happen unless good powder be used. Ordinary miners' powder will not often bear this kind of dilution. It is easy now to apply this principle to military mining, where the object is to produce as extensive a shock as possible. Mathematicians have calculated the globes of compression for certain charges; but it will be found that these vary so much, according to the strength of the material, that the conclusions cannot be depended on. This, however, is a very important problem, because the destruction of a work depends on the area of the base of the paraboloid, or whatever else the figure be, which the explosion produces. We cannot, however, enter further on this subject, as it would lead us beyond our limits.

On the Choice and Examination of the Materials.

Nitre, as it is imported from India, whence all that is used in this country is procured, is mixed with much dirt and with some salts, consisting chiefly of the nitrates and muriates of lime, and of muriate of potash. As the deliquescent salts, in particular, are extremely injurious from their property of attracting moisture, it is most important that the nitre to be used in gunpowder should be thoroughly refined.[1] For this purpose rain-water ought to be used if possible, and if not, such river or other waters as are found, on trial by the appropriate tests, to contain the least quantity of saline matters. The nitre is first boiled, and the grosser impurities separated by filtering through hempen bags, after which it is crystallized. After draining, one washing is sufficient to render the first crystallization sufficiently pure; but the subsequent ones require repeated solution and crystallization before all the foreign salts can he separated. The loss which rough nitre sustains in refining is termed the *refraction*. But we need not dwell on this subject. We shall only add, that no nitre ought to be used unless it will stand the tests of nitrate of silver and of carbonate of potash, without exhibiting a precipitate.

It is held necessary that the nitre should be thoroughly dried; and, accordingly, much unnecessary labour is bestowed on this subject, since it must be moistened in the mill when the composition is submitted to the rollers. The only real use in drying it is to enable the workman more easily to allot the true weight, which might equally well be done by an average and an experiment. We should scarcely have noticed this, but that the French manufacturers boast much of the superiority which they derive from reducing the nitre to minute crystals, by agitating the solution. In the royal mills it is further the practice to fuse the nitre into large cakes. By this method it is speedily dried, easily stored away, and protected from depredation. These advantages are held to be sufficient to compensate for the expense; but it ought to be remembered that there is a degree of hazard in the process, as, if the salt should be overheated, it might be so far decomposed as to have a portion of potash united with it.

Sulphur, as it is received from Sicily, the great emporium of this commodity, is mixed with a considerable proportion of lime, whilst a portion of it is also combined with that substance, forming calcareous hepar, or sulphuret of lime. From this and the grosser accidental matters it is purified by melting; the sulphuret and the earth subsiding to the bottom of the mould, so as to admit of being mechanically separated. This residue, yielding no more pure sulphur by that process, is afterwards submitted to distillation. When the sublimed material is to be used, it requires previous washing, till it be entirely freed from the sulphuric acid adhering to it, and it may be tested for this purpose by means of the muriate of barytes. The fused sulphur, if doubted of, may be submitted to combustion, and the residue noted; but a little deficiency in the purity of this ingredient is of no moment.

With respect to the charcoal, there is considerably more nicety required than is generally imagined. The soft woods have been preferred from time immemorial, since even in the receipt of Magnus Græcus, formerly quoted, the willow is mentioned. The poplar and many others have been used abroad; but in this country those commonly adopted are the white willow and the alder. Even among these soft woods there is a considerable difference, as our own experiments have shown; and in them it was proved that the greatest explosive power, *cæteris paribus*, was produced by the wood of the *Rhamnus frangula*, commonly called black dogwood, as we shall show more particularly hereafter. The hard woods are invariably rejected, and with justice; though the reasons for this practice, which are derived from the presence of salts in these, are not the causes of their inferiority, certainly not the only ones. It is nevertheless true that no wood which contains carbonate of potash, or other deliquescent salts, is fit for the purpose, and for the most obvious reasons. This is the case in the oak, elm, fir, and other trees. But there is another reason for the badness of these kinds of charcoal, the cause of which is not so obvious, although it is evidently connected with their hardness. To us it appears to depend on the small proportion of hydrogen combined with the carbon in these charcoals, compared to that which exists in the produce of the softer woods. Even these can be reduced to the same state by overheating. Thus the hydrogen is dissipated, and the charcoal becomes so hard as to scratch steel; in which case, however obtained, it is always unfit for powder.

As this subject is yet obscure, from our imperfect acquaintance with the true nature of charcoal, and with the modifications of which it is susceptible, it becomes necessary to have recourse to experiment, for the purpose of determining, at any rate, the proximate cause of this difference in the explosive powers of the several kinds. Various trials have accordingly been made, as well by ourselves as by the French chemists; and, for brevity's sake, we add the most important results in the subjoined table. We are not informed of the process which was adopted by the French for measuring the gas; but in our own we had recourse to the pneumatic apparatus, using it in the manner which is described in another part of this article for collecting the total produce of the combustion of gunpowder. The mixture, in the French experiments, consisted uniformly of 60 parts of nitre and 12 of the charcoal submitted to trial. In our own they were varied, and the results taken from those in which the combustion of the charcoal was completed, and the quantity of gas the greatest. As no more nitrous acid could be decomposed than there was coal present to burn the oxygen, it is plain that in these the results are correct.

	Prop. Parts Gas.	Solid Residue.		Prop. Parts Gas.	Solid Residue.
French Hemp stalks	62	12	French Fir	66	30
... Asphodel	62	20	... Chestnut	66	36
... Vine	64	20	... Hazel	66	33
... Peartalks......	62	21	... Lamp black...	54	44
... Spindle tree (*Euonymus europeus* ...	66	28	... Coke...........	54	45
			... Filbert	72	30

These results are such as to prove that there are important differences in the produce of gas; but, with regard to practice, they are of very little value, as few of the substances submitted to trial could be used. To admit of comparison between our own experiments and these, we shall reduce our proportions to the same standard, by taking our scale from the filbert at 72. We neglect the residue, knowing that it proves nothing, as the results are uncertain, in consequence of the irregular absorption of water, and partly from the impossibility of collecting the solid and the gaseous matters both from one charge.

	Gas.		Gas.
Filbert	72	Oak bark...........	58
Oak	61, 63	Animal charcoal...	50, 46, 42, 40
Mahogany	58	Coke..................	52, 48
Elm	62	Lamp black.........	54, 52
Willow, *Salix alba* ...	76, 78	Oak charcoal overheated	54, 56
Alder.....................	74, 73	Willow ditto	59, 64, 66
Black dogwood, *Rhamnus frangula*	80, 82, 84		

These various results, and some others which we have thought it unnecessary to record, may, in a certain degree, depend on inaccuracies in the experiment; but in the greater number they arise from real differences in the charcoals from the same substance, produced, as we before insinuated, by overheating. This is apparent in the two cases above cited of oak and willow; but in some trials, the differences were even greater. Coke and animal charcoal are particularly liable to vary.

---

[1] Were it not for its hygroscopic properties, nitrate of soda might be advantageously substituted for nitrate of potash in the manufacture of gunpowder, on account of its containing a much larger amount, by weight, of gas-forming ingredients.

It is evident from the preceding table that the best charcoals for gunpowder must stand in the following order: Black dogwood, willow, alder, filbert. From the French tables, in which we do not, however, place much confidence, we may add, consecutively, hazel and the spindle tree; but our own trials raise these to 70 at least in the scale. Such, at present, are the results of these trials as to the best charcoal; but we are by no means satisfied that we have yet found out the best wood for this purpose. The experiments are laborious; yet we think the subject deserving of more attention than has yet been bestowed on it. With respect to coke and animal coal, they stand very low in the scale, as the over-hardened wood charcoals do; and, in all cases, there is a direct relation between the produce of gas and the facility of combustion under ordinary circumstances.

To satisfy ourselves by trials of a more direct nature, and more applicable to practice, we chose a method derived from the flight of rockets, as less liable to disturbance from collateral causes than any practice with pieces of ordnance. The rockets were of compound dimensions, and were all made with the same proportions, and driven by the same hand, so as to ensure all possible uniformity, the only variation being in the nature of the charcoal. The vertical elevations were taken by two quadrants at the same time, and all the flights that deviated from the perpendicular rejected. The mean vertical ascent of a great number of those made with willow, alder, and dogwood, was 480 yards; but between these three charcoals, the differences were so great as to give various results, which may be represented by the following numbers:—Dogwood, 515, 550, 525; willow, 470, 480, 490; alder, 455, 460, 470.

Greater accuracy is not attainable in this way, as may easily be conceived by those who know by how many collateral circumstances a rocket is influenced; but these trials are quite sufficient to justify the general inference made from the experiments in the pneumatic apparatus.

It has been held that the charcoal for gunpowder ought to be made in cylinders or retorts by distillation; and this expensive process is consequently adopted. It is doubtful if this is not a mistake of the *causa pro non causa.* Pit charcoal, being made in coppice woods, is always the produce of oak; and it is probable that this wood, if charred in close vessels, would be even worse than it is now. There is more danger of overheating in the retort than in the pit, while the wood is not better burned; and hence, by a careless management of the process, even the charcoal of willow or alder may be rendered as bad as that of oak. Considering these various circumstances, charcoal requires to be submitted to three tests. It ought to act as little as possible, mechanically, even on copper; it ought to exhibit no salts on being treated with boiling distilled water and tested; and it ought to be thoroughly burned. The best test of this latter circumstance is its giving out no smoke when heated.

A new and economical method of distilling charcoal was invented by Sir William Congreve. Subsequently, but without any knowledge of what had been done, the same process was suggested in America by Dr Bollman, to whom we are indebted for the cheap method of purifying pyroligneous acid, and rendering it a substitute for common vinegar. In this process the retorts or cylinders are ranged in a row, a gas pipe from each being conducted to the bottom of the next in succession. By means of a fire under the first alone, the distillation of the whole may be conducted together; the gas which issues from that one being sufficient to char the next, and so on in succession to the end of the chain. The acid is collected in this case, as in others, by means of a separate pipe arising from a lower point in the retort.[1]

Before we dismiss this important department of the gunpowder manufactory, we must refer to the property which charcoal possesses of absorbing and retaining water, and which we have ascertained to be different in the different kinds of wood. It is from this hygrometric power that gunpowder attracts moisture, even when the nitre has been perfectly purified; a circumstance which materially interferes with its rapidity of inflammation, and consequently with its strength. But as the various hygrometric powers of different charcoals have not been properly examined, we can communicate no information on this subject which is worth recording.

Manufacture of Gunpowder.

Grinding.—The first part of the process consists in pulverizing all the ingredients separately, after which they are weighed and mixed in a general and rude manner before being submitted to the mill. In some countries a pestle engine is used, or a stamping-mill; but it is subject to more hazard and inconveniences than the grinding-mill which is adopted in this country. This is formed on the model of the common bark-mill, and with two rollers at different distances from the axis, so as to cover the whole bed. The weight of each roller is commonly about three tons, and they are generally made of limestone, although iron cylinders have been adopted in some works, with the gudgeons working in gun metal. The bed, which is surrounded by a wooden margin, is of the same materials; and the whole house is built of slight-framed wood, to diminish the evils that might arise from a casual explosion. A wooden rake follows the rollers, for the purpose of bringing the mixture under the cylinder; and the motion is communicated either by water or by the power of horses.

The mixture being distributed on the stone, to the amount of forty or fifty pounds, is moistened with distilled or rain-water, but so as not to be wetted. It is barely sufficient to prevent the dust from flying. According to the velocity, the grinding is perfected in a space of time varying from three to seven hours; and it depends on the inspector to determine by trial for each velocity when the mixture is perfect. After that, time is a sufficient measure. The removal of the *mill-cake*, as it is called, requires caution, as it is commonly at this time that the explosions take place. These, indeed, will generally be produced if the bed and cylinder should come into contact while they are moved round slowly, to enable the materials to be taken out; the friction, under so great a weight, even of the purest limestones, or of iron, being sufficient to inflame gunpowder. To prevent this risk, a thick piece of hide is carried before the cylinder as the powder is removed, and by this plan the contact is prevented.

Pressing, Granulating, and Drying.—The mill-cake thus completed is gunpowder, and may be granulated. But it is yet not so firm as it can be rendered by further pressure; and that property is very essential to its durability in travelling. For this reason, it is further condensed by pressure of about 75 tons per superficial foot, by means of Bramah's hydraulic engine; for which purpose the mill-cake powder is placed on the bed or follower of the press, and separated at equal distances by sheets of copper, so that, when taken out, it is in the form of thin solid cakes, termed *press-cake:* this is equal in hardness to that of many stones, and its specific gravity is also increased. By being divided into cakes of an inch or more in thickness, it can be more easily broken into pieces for the granulating engine.

---

[1] In the manufacture of the best kinds of sporting powder, a plan has been introduced in France for carbonizing the wood by means of high-pressure steam, producing what is called *charbon roux*, on account of its rusty-red colour. In the *Annales de Chémie et de Physique* for 1848, will be found a memoir on this subject by M. Violette, in which he insists upon the importance of preparing the charcoal from the same kind of wood at a uniform heat, since it varies greatly in its properties according to the temperature at which it is made. At the temperature of 250° C. and below, the wood is but imperfectly carbonized; at 300° C. and about, the red charcoal is produced; at 350° C. and beyond, black charcoal is formed. The advantages of the red over the black charcoal are its greater yield, from 40 to 42 per cent. of charcoal being obtained; while at from 350° to 400° C., only from 26 to 30 per cent. were obtained, and the force of the powder made from red charcoal is greatly augmented. From 25 to 30 kilogrammes of wood can be carbonized in two hours, and six charges can be passed through the apparatus per day. The super-heated steam effects the carbonization with great facility, and the temperature can be exactly maintained by means of a bath of tin or fusible metal.

The press-cake is crushed between hollowed rollers of different successive gauges, and is next passed to the granulating engine. This consists of a number of sieves made of strong vellum, perforated by punched holes, and supplied with top and bottom covers, like those used by druggists. A platform, to which a horizontal circular motion is communicated by machinery, receives a number of these, which are fixed in it. The lumps of the press-cake are introduced into each of these, together with two flatted spheroids of lignum vitæ or other hard wood. During the rotatory motion the lumps become thus broken into smaller fragments, which fall through the holes, together with the dust; the *grained* powder, as it is called, is received by hair-cloth sieves, which allow the dust to pass into a receptacle below.

It remains to separate the grains according to the sizes that are required; and for military purposes these are three: one for large ordnance, another for musketry, and a third for pistols. The powder generally used by sportsmen is of still finer grain than the last. The separation is performed by means of wire gauze, or strong silk gauze, of different apertures; the sieves being commonly cylindrical, and turned by the machinery. At the same time the dust is separated, and afterwards returned to the press.

The last operation is known by the name of *glazing*, a term literally true in the case of sportsmen's shooting-powder. But the real object of this operation is to take off all those acute angles from the grains, which would otherwise be ground off in travelling, and thus produce great inconveniences, by introducing dust into the casks. This process is performed by causing the separate classes of grains to revolve in cylinders so constructed as only to let the dust through; and the mutual friction of the grains produces the desired effect. When it is required to give the powder a brilliant surface, as is the case with fine sportsmen's powder, the cylinder is lined with a woollen cloth; and sometimes, if a high polished gloss is desired, some black lead is introduced into it. But these are matters of mere ornament.

Although the powder thus completed appears dry to the touch as well as to the sight, it contains a considerable quantity of water. This must be separated by drying. In hot climates exposure to the sun is sufficient; but in most cases artificial heat is required. In France a complex process was adopted by passing heated and dry air through a closed chamber, with the intention of diminishing the risk of explosion; but, with any moderate degree of care, it may be done in any manner. In some of the older works the stove in use was a closed room with air-holes above, heated by means of an iron cupola or large pot, to which a fire was applied outside of the building; the temperature being regulated by a thermometer fixed in the door, and indicating the heat externally. In this room the powder was exposed in flat trays round the circumference. Lately, the method by steam pipes has become generally adopted; and in this way every possible security, real as well as imaginary, is obtained.

Analysis of Gunpowder.

It is often useful, and frequently indispensable, to analyse gunpowder. This process will, indeed, generally supersede the necessity of *proving* by the usual methods, as it is always certain that a specimen of gunpowder, well made, will produce the best proof. It is particularly convenient in the case of gunpowder purchased from merchants, or by contract; as, from the several causes which may easily be conjectured, such an article may be deficient in the quantity or in the quality of the saltpetre, or in both. It is useful, moreover, in the case of damaged powder, returned from military and naval service; as we can determine by these means whether it has been wetted by rain or by sea water, or whether any portion of the nitre has been washed out. Powder thus damaged by fresh water only, and otherwise uninjured, may be committed to the mill and restored at a very trifling expense. If the saltpetre is diminished, it can thus also be restored; but, on the contrary, if the damage has been produced by sea-water, it becomes necessary to destroy the powder for the purpose of extracting the nitre.

By washing the powder, previously weighed in a filter, with hot distilled water, the nitre is dissolved, and admits of being crystallized and weighed. The tests, nitrate of mercury and carbonate of potash, may then be used to determine its purity. Thus it may be ascertained whether, in a new sample, the nitre is in sufficient proportion, and whether it has been well purified; and in a damaged one, whether the injury has arisen from fresh or from salt water. It only remains to examine the proportions of the charcoal and sulphur; the sulphur may be dissolved out by means of bisulphide of carbon, evaporating and weighing; the charcoal that is left may also be weighed, but it is scarcely necessary to perform the latter part of this analysis, as the manufacturers are under no great temptation to assume a wrong proportion of sulphur and charcoal, although the joint quantity of the whole may be in excess.

Analysis of Gunpowder after Explosion.

To a certain extent, at least, an analysis of gunpowder after explosion is necessary, for the purpose of procuring data whence its force may, *a priori*, be calculated. The rest is only matter of curiosity, and we have borrowed the determination from the experiments of the late Mr Cruickshank. As far as this analysis may differ from that of others, it must be recollected that the separation of mixed gases is not a very easy problem. The mere collection of the total gaseous products is easy; and had the same method been followed by Robins and others, less difficulty would have been found in their computations. Had Count Rumford and others adopted so simple an expedient, they would not have had recourse to the expansive force of steam, or of the air contained within the charge, for an explanation of the cause and nature of the force.

By ramming a hundred or one hundred and thirty grains of powder into a narrow metallic tube, furnished with a long handle, it is easily caused to burn under water, as the combustion is slow and safe when it is thus condensed; and this quantity is sufficient for any purpose of experiment. The tube being plunged under the water with its mouth downwards, under the bell-glass of the pneumatic apparatus, the powder may be lighted without any loss. This is done by introducing into that part of the tube above the charge, which is purposely left empty, a crooked wire heated to redness. After the hot wire and the tube in this position are immersed under the bell, the former is brought into contact with the charge. To prevent the water from absorbing any portion of the carbonic acid, sulphuric acid may be added to it, as well as many other matters too obvious to mention; or else it may be heated. Thus the gaseous product may be collected and examined at leisure, by the means which chemistry furnishes, and which our limits will not permit us to detail.

To collect the solid product, it is most convenient to use a glass vessel, on account of the certainty of obtaining the produce, which is, in great part, carried up in smoke, and adheres to the receptacle in which the powder is burnt. But we need not describe the numerous modes in which this object can be attained; and shall only add, that to diminish the hazard, the powder employed for this purpose may be wetted without affecting the results.

The chief gaseous results of the analysis of gunpowder are carbonic oxide, carbonic acid, nitrogen, and sulphurous acid; while the solid residue consists of carbonate and sulphate of potash, sulphuret of potassium and charcoal. The maximum gaseous volume is produced by the formation of carbonic oxide and sulphurous acid with the liberation of nitrogen. With 1 equivalent of nitre, 1 of sulphur, and 3 of charcoal, the nitre yields 5 proportionals of oxygen, of which 3, combining with 3 of charcoal, furnish 3 of carbonic oxide gas, and the remaining 2 convert 1 of sulphur into sulphurous acid gas, and the single proportional of nitrogen is disengaged alone. Hence the gaseous volume produced by 130 grains of gunpowder, equal in bulk to 75·5 grains of water, or $\frac{3}{10}$th of a cubic inch will, at the atmospheric temperature, be as follows:—

	Grains.	Cubic inches.
Carbonic oxide	42	141·6
Sulphurous acid	32	47·2
Nitrogen	14	47·4
		236·2

being an expansion of 1 volume in 787·3. But as the temperature of the gases at the moment of formation must be incandescent, this volume must be estimated at three times the above amount, or considerably more than 2000 times the bulk of the solid.

This theoretical account does not, however, quite agree with the products obtained by experiment, especially as regards the evolution of carbonic acid, and the residuary sulphuret of potassium. Professor Graham has therefore given the following view of the results of the deflagration as being more consistent with experiment:—

Before Combustion.		After Combustion.
3 Carbon.	3 carbon	3 carbonic acid.
Nitrate of potash.	6 oxygen nitrogen potassium	—nitrogen.
Sulphur.	sulphur	sulphuret of potassium.

The sulphuret of potassium, on coming into contact with the air, becomes converted into sulphate of potash, thus giving rise to the white smoke that follows the explosion of gunpowder.

Gunpowder ignites at a temperature of 600° Fahr. It is not readily ignited by flame, as may be shown by putting a heap of it on a cork, contained in a saucer, and then pouring in ether or spirits of wine; the latter on being ignited will surround the gunpowder with a copious flame, and not fire it for a considerable time. A piece of gun-cotton may be placed on a heap of gunpowder and fired without igniting the powder. Gunpowder may even be sprinkled on the top of gun-cotton, and be scattered about by its explosion without igniting; but this is partly due to the greater rapidity of action of gun-cotton. (See GUN-COTTON.)

On the Sizes and Forms of the Grains in Gunpowder.

The variety in the effects of gunpowder, arising from differences in the sizes and forms of the grains, has been an object of much inquiry. The conditions of the problem are somewhat complicated. Within certain limits, which gunpowder made of nitre cannot exceed, rapidity of inflammation is essential to the production of a full effect. Not to inquire into other causes, without this property, a part of the charge is rendered useless by being blown out unburned; an accident not uncommon on ordinary occasions. This may also happen from the form of the piece and that of the charge; it will occur in a long charge or in a short piece, or, most of all, when both are united. Hence variations in the effect of gunpowder, which are independent of its quality, and which will render computations founded on that circumstance alone deceptive. As we have not room to dwell on this subject as it deserves, we must refer our readers to Robins and others who have written on it.

Now, this rapidity of inflammation may be attained, in some measure, in two ways; by intense heat, and by facility of transmission of the flame. But if a charge is considerable, no intensity of heat can compensate for the absence of the second condition. To put an extreme case: If the eight-pound battering charge of a 24-pounder were a single grain or lump, it requires little thought to perceive that the shot would have quitted the gun before the charge was half burned. Hence granulation is as necessary for ensuring the full effect as it is for convenience. And thus, also, we are led to the cause of the bad consequences of hard ramming. A charge very thoroughly rammed, and lighted at the anterior end, would burn like a fuse or a squib; if lighted by a touch-hole, it will be blown out like a shot. Thus the rapidity of the inflammation is secured by multiplying as much as possible the intervals for the passage of the flame, or by diminishing the size of the grains. Yet there is a limit even to this; and as that can only be determined by experiment, it is from such trials that the grain for the smallest charges has been fixed. As the charge, however, increases in dimension, the volume of flame and the intensity of the heat produced admit of a grain of greater bulk, or one containing, in a given dimension, a smaller number of intervals. Much refinement on this subject being, however, unnecessary, one size is used for all ordnance; whilst an inferior size is made for muskets, and one still less for pistols. The powder manufactured for fowling-pieces is also of the smallest size.

But there is a further element concerned in this question; and that is, the different specific gravities of the different sizes of powder, or, what is especially to the purpose here, the different spaces occupied by the different sizes. The same measure which contains 172 grains of the smallest, contains 180 of the medium, and 195 of the largest. If powder be measured instead of weighed, it is evident that there will be one-ninth more of the large than of the small grained in a given charge. If weighed, the larger will occupy about one-ninth less space. In either case the greater force will be excited by the large-grained, presuming that the inflammation is perfect. When it is weighed, as is the correct practice, it will not be very difficult to calculate the difference; as the force of the expanding fluid is in a certain inverse ratio of the space in which it is confined.

To increase the rapidity of inflammation, the French have manufactured spherical powder. The principle of the process is similar to that used by confectioners in making comfits. Angular grains are rolled in machinery adapted to that purpose, in powder dust slightly moistened; and thus small globules are formed. This grain is less liable to wear in travelling, from the absence of angles; but it is at the same time more tender, and less able to bear pressure than pressed powder. Nor do the French experiments, either by the eprouvettes or the tables of practice, prove its superiority; on the contrary, the average results of its comparison with ordinary powder are unfavourable and this also was observed in our own trial. Hence it has not been adopted in Britain.

Proving of Gunpowder.

To ascertain, by practical trials, the strength of gunpowder, is not merely a matter of curiosity, but of absolute necessity. As the force in battering ordnance, and the range in mortar and howitzer practice, are regulated by the quantity of the charge, it is obvious that no regular practice in the field, or consistent results, will be obtained, unless the standard of strength in the powder is both known and invariable. This is particularly the case with mortar practice against small works or redoubts, or against the enemy's trenches; and also with howitzer practice against moving columns in the field. An invariable standard is, unfortunately, impossible; but it is always something to approximate to it. In military arrangements, a proof is also requisite, for the most obvious reasons, when powder is purchased from merchant manufacturers; not only that a minimum standard of strength may be fixed, but that, as far as is possible, the various qualities furnished may be reduced by mixture to a uniform standard.

It is usual, in the *first* place, amongst the workmen, as well as the merchants, to form a judgment of the quality of gunpowder by the aspect and firmness of the grain; and the latter, indeed, is a quality which is indispensable, if it is to be exposed to much land-carriage. The nicety of tact required for this is, however, only to be attained by practice, as in all other species of sampling. The moisture is judged of by weighing, and by subsequent drying and comparison. The quantity of this is a question of profit and loss in the purchase. But it is more important to ascertain its hygrometrical powers, by exposure to moisture after drying. That is the best which gains least weight by this operation; nor, in any case, should the absorption of water amount to ¾th per cent. It is also a common practice to try it by what is termed *flashing;* but this only serves to show whether it has been thoroughly ground; if not, the charcoal will produce sparks.

The trial of force is made by eprouvettes of different constructions, or else by practice. The most common eprouvette is a short chamber, provided with a gun-lock, the orifice of which is closed by a cover, connected with a graduated and ratchet wheel and spring. The quantity of the wheel's revolution is the esteemed measure of the force. But, often as this machine has been varied and improved, the results are so irregular, that it may fairly be considered as useless. Various other instruments for this purpose have been invented and tried; but, without figures, we could not render their constructions intelligible. Regnier's does not materially differ from the preceding in its principles; and the results are equally unsatisfactory. His hydrostatic one appears to be still worse. We may say the same of that described by Saint-Remy, and of another recommended by the Chevalier d'Arcy; and, of the whole, we would remark that the leading fault is want of simplicity. In a case like the explosion of gunpowder, where so many disturbing forces are always at hand to vitiate the true results, we cannot be too careful in eliciting all unnecessary causes of disturbance. If there is any one class of machinery in which simplicity is indispensable, it is that which belongs to gunpowder, under any of its relations.

We consider, however, that, as an eprouvette, Dr Hutton's pendulum is as free from exception as any machine can be. The disturbing forces are nothing, or as little as possible; the charging and firing admit of great uniformity; and, on trial, the consistency of the results justifies the expectations formed from its simplicity. In this pendulum, the barrel is fixed upon the bob, and the force of the gunpowder is therefore measured, not, as in Robins', by the impulse of a shot, but by the recoil. The indication of the extremity of the arc of vibration is made by a hand continuous with the pendulum rod, which moves an index furnished with a spring sufficiently strong to retain it at that point of a graduated arc where it was left by the movement of the hand. The barrel used for this purpose is an inch in diameter, and is charged with two ounces of powder put in loosely, without wadding or ball. In this, as in all other cases of eprouvettes, the standard of strength is arbitrary; and, for service, is assumed from the best average of gunpowder manufactured by government. The goodness of particular specimens is estimated by their agreement, or otherwise, with this standard.

Notwithstanding, however, the apparent accuracy of this method, artillery officers, both in France and in England, are not satisfied with it as a method of proving powder for service. It is perhaps right that practical men should, in a matter of so much importance, rely only upon such a method of proof as agrees best with the particular objects for which the material is intended. Yet it should also be recollected, that all Robins' conclusions respecting the force of gunpowder were drawn from experiments made on his ballistic pendulum, and that the much more accurate ones of Dr Hutton, on which we now rely, were the results of the practice with that pendulum which we have just described.

The method of proving, then, adopted both in France and England, consists in real practice from a mortar at short ranges. In France a mortar is used of which the diameter is 0·191 metres, or nearly eight inches English, and that of the touch-hole somewhat less than two lines. The diameter of the ball is 0·1895 metres, and the windage consequently is ·0015. The weight of the ball is about sixty pounds. A troublesome verification of the diameter of the bore, of the vent, and of the shot, is made for each day's practice. The mortar is condemned when the diameter is enlarged to 0·192, or if that of the vent becomes ·0005 more than it ought to be. A difference of windage, amounting to ·0002 metres more than what is allowed, condemns the shot, or, as it may happen, the whole apparatus.

All these verifications are so tedious, and the wear of the mortar, the vent, and the shot, so rapid, that it becomes inconvenient and impossible to follow them so nicely in practice when there is much business. It is, therefore, found more convenient to make a standard trial for each day's proof, and to refer all the others to this one; instead of trying to preserve what becomes impossible in practice, an absolute and invariable range.

The English proof-mortar nearly corresponds with the French, it being of the eight-inch calibre, and of brass. The shot is turned and polished so as to be true, and to have at the commencement the least practicable windage. During the progress of use, as the windage increases from the wear both of the bore and of the shot, the range becomes contracted; a circumstance which also follows from the enlargement of the vent, in consequence of which a greater proportion of the generated air escapes at that aperture. But, from the practice adopted with us, these variations are of no moment, till the range becomes contracted so as to render it expedient to replace the shot or the mortar, or both.

The quantity of powder that is used is four ounces, and the mortar being elevated to forty-five degrees, the range is measured in each trial. If the standard range for the day is 225 yards, the powder that gives a range of only 200 is rejected. The chief precautions requisite to procure fair results in this comparative method, are, to take care that the level of the platform and the elevation of the mortar are subject to no accidents; that the powder be fairly placed in the chamber; that the priming tube always reaches to the same depth within the charge; and that the mortar be brought to the same temperature at each experiment. For this purpose, it is to be cooled with water.

Musket powder is submitted to a different species of proof, founded on the same views of rendering the proof for each kind as nearly corresponding as possible with the purposes for which they are designed. A barrel fitted with a turned steel ball, and with as little windage as possible, is used for this purpose. The ball is discharged at the distance of a few yards only, against a compound butt, made of elm planks an inch thick, soaked in water, and separated at a short distance from each other. The extent of the penetration is the proof of the strength of the powder; and the trials in this case also are referred to a standard experiment made each day. Before concluding this subject, we must add, that trials are also made for the purpose of ascertaining the hygrometrical property of the powder to be purchased or issued. This is done by exposing a quantity for a given time in a box perforated with holes, and in a damp room, and then submitting it to the same proof.

Powder from Chlorate of Potash.

To increase the strength of gunpowder has been a favourite project with inventors at all times; most of them forgetting that the same end can be attained, as far as it is attainable, by augmenting the charge, and that neither the one nor the other is practicable without an entire reformation of the whole system of artillery. Could the force of powder be increased one-half, for example, it would be necessary to condemn almost every gun in use; and not only every gun, but every carriage, breeching, ringbolt, nay, we might almost add, every ship in the service. And supposing a new species of ordnance to be invented to suit the new powder, it would require at least one-half as much more of weight in guns and mortars; the same in gun-carriages, with additional strength in every object concerned about them. In the field, in the same manner, an increased number of horses would be required. This view presumes that the object is, what in fact it always has been with inventors on this subject, to gain additional force or range. If the purpose is only that of being enabled to reduce the quantity, and thus diminish the bulk and trouble of transportation, it is so trifling an object as scarcely to be worth attaining. With regard to the main intention, or that of gaining greater range and force, it is only necessary to say, that the powder is already too strong for the artillery.

As soon as chlorate of potash was known, it became obvious that it would not answer the same purpose as nitre, but, from its more energetic action, produce a more rapid combustion. It was first proposed and made by M. Berthollet in 1786, and was long known under the name of oxymuriate of potash; but an accident having happened from it at Essone, by which many people lost their lives, it was abandoned. The proportions used were 80 of chlorate, 5 sulphur, and 15 charcoal. Afterwards they attempted to make a modified compound, by using only a proportion of it with the nitre; but after various trials of this kind, the whole project was abandoned.

We have repeated Berthollet's method, at different times, and on a very large scale, without accidents; but we consider that the proportion of oxymuriate is too large, or at least that it is larger than is necessary. A better proportion appears to be 75 of chlorate, 5 sulphur, and 20 charcoal. As this compound is very easily exploded by friction, it is necessary to be extremely cautious throughout the whole process, particularly in the granulations; nor is it safe to make more than one pound at a time. Of course, it may be mixed in wooden mortars, as it requires no large apparatus.

The great objection to its use is the facility with which it is inflamed by friction, or by a hard blow. It is also more expensive than nitre. It also corrodes the barrels very quickly. In fowling-pieces it is, however, of use; being the detonating priming of Forsyth's and Manton's gun-locks.[1] We may add, that very good powder may be made from this salt and charcoal alone, in the proportion of eighty to twenty; but the grain is not very compact, and it is subject to the same faults as the former.

The action of this powder on the shot in a charge is very capricious, and far from intelligible. In the French trials, it was found to give ranges sometimes double and sometimes triple those of common powder, using the same weights. In various experiments made in this country, the ranges were double in a majority of comparisons, when moderate charges were used. But, by increasing the charges beyond this, the ranges, instead of increasing in the same ratio, began to contract; double the quantity producing but a moderate increase in the range, and a third proportion making an addition still less than the preceding. This, however, agrees with Robins' experiments on common gunpowder; and he has accounted for it by what he calls the triple resistance; proving, as he thinks, that whenever the initial velocity exceeds 1142 feet in the second, a vacuum is formed behind the shot, which, by increasing the resistance before it, speedily reduces the velocity to what it would have been with a smaller charge. We need say no more respecting a compound, the use of which is not likely to be ever extended beyond its application to the detonating gun-locks.

A white gunpowder has been prepared by mixing chlorate of potash with yellow prussiate of potash and sugar.

Keeping and Restoration of Powder.

Powder for service, whether by sea or land, is kept in barrels, containing each one cwt., the size of which is nearly that of a ten-gallon cask, and they are hooped with copper. It being difficult to keep dry casks water-tight, as indeed it was not thought necessary that they should be so, much powder was always rendered useless on service by wet. Lately copper linings have been very properly introduced, and the casks are now water-tight. As great quantities of powder, however, always have been, and always must be, returned unserviceable, it is an important object to be able to restore it, or render it useful, in the most economical manner.

Sometimes the grain is merely adhering, and can be shaken loose again; and this effect is not unfrequent even in magazines on shore. Such powder, when dried by restoring, appears to be sufficiently perfect; but it will be found that it is increased in bulk, and has become spongy and tender. On examination by the magnifying glass, it will also be perceived that the nitre is partially separated. Powder which has once undergone this change is deteriorated, yet is still fit for all ordinary purposes. It is not strong enough, however, to bear travelling; and should it be required for that purpose, it ought to be re-milled, and granulated over again.

When the casks have been opened on service, before being returned, it is necessary to examine carefully whether they do not contain nails, or other foreign matters, an accident not uncommon. In such a case it is unsafe to commit them to the mill, and they must be reserved for extraction. When the powder has been so wetted as to be nearly formed into lumps, it is first necessary to examine, by the test of nitrate of mercury, whether the damage has been done by fresh or salt water. If by the latter, it must also be sent to the extracting house. If it has been very thoroughly wetted, even by fresh water, it will often be found that some of the saltpetre has been washed away. In this case it must be analyzed, so far at least as to determine the proportion of saltpetre wanting, which must be added to it in the mill. In the process of extracting, nothing more is necessary than to boil the powder in pure water, and to filter the solution through thick woollen bags. The crystals are purified exactly as in the case of rough nitre. This is a wasteful process, however, and, in all cases where it is possible, re-milling is to be preferred.

---

[1] Percussion caps for muskets are filled with a mixture of equal parts of fulminating mercury and chlorate of potash, fixed by a varnish: caps for cannon are charged with two parts of chlorate of potash, two of native sulphuret of antimony, and one of powdered glass: the last ingredient takes no part in the chemical action but serves to promote friction. Fulminating mercury and collodion are also being tried for caps.

Accidental Explosions in Powder Manufactories.

This is a subject which deserves far more attention than it has yet received; and we can only regret that our researches do not enable us to add more to the present suspicions as to the causes of these, than the little which follows. That want of sufficient care is the general source of these disasters is, however, certain; as certain merchants' mills have been celebrated for them, whilst in others, as well as in those belonging to the government, they have been extremely rare. Such accidents may take place in any part of the works; but they are most frequent, as well as least injurious, when they happen in the mills, the quantity of powder in these never exceeding fifty pounds. It ought at least to be an invariable rule to remove each charge to the pressing-house as soon as it is completed.

We have already hinted at the cause of the explosions in the mills, when they happen at the time of removing the powder from beneath the stones. As stamping-mills are not used in this country, it may be thought superfluous to remark, that, in these cases, this accident sometimes happens from attempting to remove, by a mallet and chisel, the lumps of powder which adhere to the pestles. It is one of the inconveniences attached to that mode of grinding. But it is also proper to observe, that the mills are sometimes blown up whilst working; and, from some examinations which we have made, we have little doubt that this has arisen from fragments of the stones falling off, and being bruised together with the powder. We indeed consider metallic rollers as every way safer than stone ones; since they can only produce fire in case of friction in contact during the removal of the charge. If iron be held objectionable, it is easy to face them with a sheet of copper; but it is proper to recollect that even thus the chances of explosion from friction are not removed. It is a great mistake to suppose that the absolute hardness of any metal is indispensable to the production of explosion in gunpowder. A blow sufficiently powerful, or friction caused by sufficient weight and rapidity, will compensate for the absence of this, in very soft metals, as well as in many other substances which do not readily give fire. Limestone we consider to be a very objectionable substance. Excepting that of Carrara, we know of none, either primary or secondary, which does not contain much silica; often, indeed, particles of quartz sand. In the secondary calcareous rocks it is universal, nor is even the finest white marble of Carrara always exempt, as is well known to sculptors. But the softness even of the purest limestones is no defence; as the friction between these is still more capable of setting fire to gunpowder than that of iron. The readiest way of putting these different substances to the test is by experiments in fulminating silver; as the irritability of this substance enables us to ascertain the facts with a moderate and convenient force.

We know of no explosions in the stove, except in one noted instance, when it was pretty well ascertained to have been produced by a workman, who had determined on suicide in this manner. In the steam stove it can never happen from overheating; but, as the floor must necessarily be dry when the workmen enter to remove the powder, instead of being wet, as it always is in the other houses, it requires additional care respecting the feet of the people employed. The only method that is quite safe, in all houses and magazines, is to oblige the workmen to labour barefooted. The heavy leather slippers in common use are far from safe; as, from not fitting well, they are frequently dragged along; in which way they may easily entangle particles of sand. It ought to be known to all powder-makers, that the breaking of a fragment of quartz, or the sufficient friction of two grains between copper, or even wood, is capable of igniting gunpowder. This is more particularly the case when the finer charcoals are used; as it is this which is the susceptible ingredient.

Explosions in the pressing and granulating houses have happened much too often, nor have the causes been ascertained. As there is a considerable quantity of powder always present here, these are of a very serious nature. It would be proper that these two buildings should always be separated, and, in the usual way, by a work of earth. The old granulating houses are far from safe, as the cranks and other parts of the moving machinery are contained within the house, which is always filled with the dust of the powder. It is trusting too much to the attention of persons, whom practice renders habitually careless, to expect that they will always keep the parts oiled. It is easy to remedy this evil by entirely separating the working machinery from the granulating engine, which may be suspended and steadied by ropes, so as to avoid all chance of friction.

In the pressing house there seem to be two sources of danger, both of which may be obviated. It is easy for powder to become entangled among the threads of the screw; and the consequence of this must be obvious. This would be remedied by adopting Bramah's press. We also think that the sudden condensation of air entangled among the fragments in the pressing box may be sufficient to produce fire. Whether this be the case or not, it will always be prudent to make the first pressure as slowly as possible, that the air may be allowed to escape.

We have observed three other causes of accident, though neither of them belong properly to the manufacturing houses. It is, nevertheless, very important that they should be generally known. Charcoal, in certain cases, is liable to take fire spontaneously, and that even in the lump. This is a case exactly analagous to the pyrophorus of Homberg; and it unquestionably arises from the same cause, namely, the presence of a portion of potassium. It is an accident which, we imagine, can only happen to charcoal made in retorts; as, in the pit method, the potassium could scarcely be expected to escape combustion. The precautions hence requisite, respecting the stowage of charcoal, and the place of the distilling houses, must be evident. When in a state of powder, and under pressure, it also has been known to inflame; and, possibly, from the same cause.

We are not aware that it is usual to keep many waggons and powder-cart tilts about powder magazines; but we do know that this has happened, and with the effect of producing fire. It ought to be generally known, for many other reasons, that fresh painted canvas, stowed close, is subject to spontaneous combustion.

Lastly, it has frequently been observed that fire was struck in closing up the powder barrels, as well on board ships as in magazines; an accident which was supposed impossible, since both copper hoops and hammers are exclusively used. We at length discovered that this accident had arisen from using cast rivets, in the surface of which the sand of the mould had become entangled. Hence the obvious necessity of using none but forged copper rivets; and since the adoption of these in the government stores. this accident has been unknown. (C. T.)

GÜNS, a free town of Hungary. See Köszegh.

GUNTER, Edmund, an ingenious English mathematician and mechanist, was born in Hertfordshire about the year 1581. He was educated at Westminster, and afterwards at Christ Church College, Oxford, where he graduated. Though he took holy orders in 1614, mathematics, which had been his favourite study from his youth, continued to engross his attention, and in 1619 he was chosen to the chair of astronomy in Gresham College, where he remained till his death in 1626. Of Gunter's written works the chief are his *Canon Triangulorum*, a table of logarithmic sines and tangents, extended to seven decimal places, and forming a sort of complement to the logarithms of natural numbers by his colleague Brigg. His practical inventions are detailed below under their respective heads.

Gunter's Line, a logarithmic line, usually laid down upon scales, sectors, &c. It is also called the *line of lines* and *line of numbers;* being only the logarithms graduated upon a ruler, which therefore serves to solve problems instrumentally in the same manner as logarithms do arithmetically. It is usually divided into 100 parts, every tenth of which is numbered, beginning with 1 and ending with 10; so that if the first great division, marked 1, stand for one-tenth of any integer, the next division, marked 2, will stand for two-tenths, 3 for three-tenths, and so on; and the intermediate divisions will in like manner represent hundredth parts of the same integer. If each of the great divisions represent 10 integers, then will the lesser divisions stand for integers; and if the greater divisions be supposed to be each 100, the subdivisions will be each 10.

Use of Gunter's Line. 1. *To find the product of two numbers.* From 1 extend the compasses to the multiplier; and the same extent, applied the same way from the multiplicand, will reach to the product. Thus, if the product of 4 and 8 be required, extend the compasses from 1 to 4, and that extent, laid from 8, the same way, will reach to 32, their product. 2. *To divide one number by another.* The extent from the divisor to unity will reach from the dividend to the quotient. Thus, to divide 36 by 4, extend the compasses from 4 to 1, and the same extent will reach from 36 to 9, the quotient sought. 3. *To three given numbers, to find a fourth proportional.* Suppose the numbers 6, 8, 9; extend the compasses from 6 to 8; and this extent, laid from 9 the same way, will reach to 12, the fourth proportional required. 4. *To find a mean proportional between any two given numbers.* Suppose 8 and 32; extend the compasses from 8, on the left-hand part of the line, to 32 on the right; then bisecting this distance, its half will reach from 8 forward, or from 32 backward, to 16, the mean proportional sought. 5. *To extract the square-root of any number.* Suppose 25. Bisect the distance between 1 on the scale and the point representing 25; then the half of this distance, set off from 1, will give the point representing the root 5. In the same manner the cube root, or that of any higher power, may be found by dividing the distance on the line between 1 and the given number into as many equal parts as the index of the power expresses; then one of those parts, set from 1, will find the point representing the root required.

Gunter's Quadrant, an instrument made of wood, brass, or other substance, containing a kind of stereographic projection of the sphere, on the plane of the equinoctial; the eye being supposed to be placed in one of the poles; so that the tropic, ecliptic, and horizon, form the arcs of circles; but the hour-circles are other curves, drawn by means of several altitudes of the sun for some particular latitude every year. This instrument is used to find the hour of the day, the sun's azimuth, &c., and other common problems of the sphere or globe; as also to take the altitude of an object in degrees.

Gunter's Scale (generally called by seamen the *Gunter*) is a large plane scale, usually 2 feet long by about 1½ inches broad, and engraved with various lines of numbers. On one side are placed the natural lines (as the line of chords, the line of sines, tangents, rhumbs, &c.), and on the other side the corresponding artificial or logarithmic ones. By means of this instrument, questions in navigation, trigonometry, &c., are solved, with the aid of a pair of compasses.

GUNTOOR, one of the districts in Hindustan, on the western side of the Bay of Bengal, called the Northern Circars. It is situated principally between the 15th and 17th degrees of N. Lat., and lies immediately N. of the Carnatic, and S. of the River Kistnah or Krishnah, which separates it from Masulipatam. It is the most southerly of the Northern Circars, and comprehends an area of about 3500 square miles, exclusively of the mountainous district on the W. This district was the jaghire of Bassalut Jung, the brother of the nizam, when Lord Clive obtained, in 1765, the Northern Circars from the Mogul, on which account he was allowed to retain it during his life; but after this it was to devolve to the Company. He died in 1782, but the country was not taken possession of by their agents till 1788. It is a low, flat country, better calculated for growing rice than the more valuable grains. Its principal seaport is Mootapilly; and its chief town is Guntoor, the population of which is estimated at 20,000. The Guntoor territory now forms one of the districts under the Madras presidency, into which the Northern Circars were divided when the present Madras judicial and revenue system was established. Guntoor, the capital, is in E. Long. 80. 30., N. Lat. 16. 18.

GUNWALE (pronounced *gunnel*), the uppermost wale of a ship or boat, or that piece of timber which finishes the upper part of the hull. The raised work above this is called the *bulwark.*

GURNEY, Elizabeth, better known under her married name of Mrs Fry, was born in 1780 at Earlham, in Norfolk. While still a girl she was noted for the benevolence of her disposition, which manifested itself even when, on reaching womanhood, she mingled freely in the gay and brilliant society which her wealth and birth opened to her. Before her marriage, however, which took place in 1800, she had retired from the gay frivolities of the fashionable world, of which she had been so fond. Settling in London, she found there a field wide enough even for her wide sympathies. She began her career of active benevolence among the dregs of the capital, by visiting them in their disease-stricken and poverty-stricken homes, and alleviating their miseries according to their several wants. She then extended her visits to the wards of hospitals; and at last found courage to do what few other English ladies of that day could boast—to entrust herself within the precincts of a jail. She there found men, women, and children recklessly huddled together;—from the comparatively innocent young girl imprisoned on suspicion of a petty theft, to the murderer awaiting his execution;—and certain, if they entered the jail with no deep stain on their souls, to leave it familiarized with every known form and degree of vice and crime. The reformation that Mrs Fry accomplished in this sink of iniquity is as well known as the means she employed to effect it; and the title of "the female Howard," which rewarded her philanthropy, by no means too strongly expressed her deserts. To carry out her benevolent designs more thoroughly, she visited the principal jails in Scotland, France, Prussia, Holland, and Denmark; and, from a study of the various systems employed in these countries, obtained some valuable practical hints for the more effective working of her own schemes. The care and labour entailed upon her by her pious philanthropy proved at length too much for her enfeebled constitution, and she died, at length, of sheer exhaustion, at Ramsgate, Oct. 11, 1844. Her death was felt throughout Europe to be a loss to humanity.

GURWAL, a native state of Northern Hindustan, under the protection of the British government, at the foot of the Himalaya Mountains, principally between the 30th and 31st degrees of N. Lat. The great Himalaya range separates it from Thibet on the N., on the S. it has the Deyrah Doone, on the E. the district of British Gurwal, and Bussahir on the W. It comprehends an area of 4500 square miles. This country formerly included the province of Kemaon, and the district now known as British Gurwal, together with the Deyrah Doone; and in 1814 the Ghoorkhas had possession of the whole tract, which extended northward to the dependencies of China. Since the country was conquered by the British, it has been distributed into distinct portions, the British government having retained possession of the Deyrah Doone, the passes of the Ganges and Jumna, at either extremity of that valley, as also the country directly eastward of the Alacananda and Mandakini; which last tract has been annexed to Kemaon, and the remainder restored to the expatriated rajah. The present boundaries, therefore, of his territories are the Alacananda, from Rudraprayag until its conjunction with the Bhagirathi, and thence to the plains by the united streams of the Ganges, and above Rudraprayag, where the Alacananda receives the Mandakini by the latter river, which has its source on the hills in the north-eastern angle of the province. This country being the commencement of the Himalaya Mountains, presents, to the southward, towards Lolldong, an assemblage of hills jumbled together in many forms and directions—sometimes in chains lying parallel to each other, but of no great extent, and often connected at their termination by narrow ridges running across the valleys at right angles. The summits of all are usually narrow, and of various shapes, and the distance between each other short; and so confined are the valleys, that it is scarcely possible within their narrow limits to accommodate a corps of 1000 men. These ranges are occasionally covered with trees; others are naked and stony, affording shelter for neither birds nor beasts. On the eastern borders of this province, amongst the lower ranges of the mountains, are extensive forests of oak, holly, horse-chestnut, and fir; and beds of strawberries are also seen (denoting the temperate nature of the climate), which equal in flavour those of Europe. From Lolldong to the Ganges the country forms, with very little interruption, a continued chain of woody hills, which extend eastward to an indefinite extent. The elephant abounds in these forests, but is greatly inferior in size and strength to the Chittagong elephant, on which account it is seldom domesticated. On the eastern borders there are hill pheasants among the mountains, which seldom, however, venture into the valleys, unless compelled by heavy falls of snow. A small portion of the country is only cultivated, a great proportion being left in the undisturbed possession of the wild animals. Gurwal is tolerably well watered by the head streams of the Ganges. The Bhagirathi and Alacananda, whose junction forms this great river, are the largest streams in the country. The Bilhang, which falls into the Bhagirathi, the Mandakini, the Pinden, the Mandaioki, the Birke, and the Dauli, all of which join the Alacananda, may be considered as streams of the second order. Most of these streams have their sources in the Himalaya Mountains; the Dauli rises on these mountains, and is one of the remotest sources of the Ganges. None of them are fordable; and they are crossed by rope and platform bridges, at the most convenient points of communication, the rocks and stones which encumber their channel preventing the use of boats. The roads are merely footpaths, carried along the slope of a mountain in the direction of the principal streams and water-courses. Those leading to Bhadrinath are annually repaired for the accommodation of pilgrims, who congregate in great numbers at this sacred resort; but they are almost impracticable for cattle. This province abounds with celebrated places of worship, which have been held sacred for many ages, although the conversion of the inhabitants to the Brahminical faith is not of any very ancient date. Four of the five places noted for the holy junctions of rivers, and celebrated for their sanctity, are within the limits of this province.

Gurwal was a dependent province on some of the neighbouring and more powerful hill states until the reign of Mohiput Shah, who declared himself independent, and built Serinagur, where he resided. His son was his successor, and he was succeeded by his uncle's son, who considerably extended the Gurwal territories to the north, penetrating into Thibet, and exacting a tribute from the rajah of Deba. Gurwal was subdued by the Nepaulese about the year 1803; when Purdumin Shah, the rajah, an indolent and unwarlike prince, at the head of 12,000 men, was defeated and slain at Gurudwara. On the occurrence of this event the inhabitants of Gurwal discontinued all resistance to the Nepaulese, who made ruthless use of their victory. After the country was conquered by the British in 1814, part of his dominions, with a revenue of L.10,000, was restored to the rajah's son. But Serinagur, the chief town, is within the territory reserved by the British; the rajah has consequently fixed his residence at Barahaut, where the details of his civil government are conducted by his own officers, and he is under the protection of the British government. The district over which he rules was estimated by the Nepaulese, when they were in possession of the country, to contain 25,720 inhabitants; a very scanty population for so extensive, and in many places so fertile, a tract of country. Under later authority the population is estimated at 100,000.

GURWAL, *British*. See KEMAON.

GUSTAVUS, ERICKSON, better known as GUSTAVUS WASA, founder and first king of the dynasty of Wasa, was born in 1490, at the Castle of Lindholm, in Sweden. On reaching manhood, he found his country pining under the cruelty and tyranny of the Danes, and himself, from his connection with the old royal house, an object of peculiar suspicion. To save his life, he fled first to Lübeck, and afterwards to Dalecarlia, where he wrought for a time as a miner in the iron-works of Fahlun. Leaving the mines, he began a kind of vagabond life, wandering in the most remote and unknown parts of Sweden, till at length he came to Rattwik, where he formed the scheme of rescuing his country from the hated yoke of the stranger. Going about from house to house, he roused the peasants to a sense of their wrongs, and at length seduced them into open rebellion. In 1521 he had collected an army of 15,000 men, and taken the stronghold of Hesteras. Town after town yielded on his advance, and Stockholm—thrice besieged in vain—at last fell into his hands, and the bloodthirsty Christian of Denmark was obliged to return in disgrace to his own kingdom. Gustavus was now solicited to accept the Swedish crown, but he steadfastly refused; and it was not till 1527 that he could be persuaded to mount the throne. He reigned with admirable success for more than thirty-three years, and his name is still held in reverence by his countrymen, in whose memories he holds much the same rank that Alfred does in that of every Englishman.

GUSTAVUS ADOLPHUS was the grandson of Gustavus Wasa, and was born Dec. 9, 1594. He was only seventeen years of age when he began to reign, but even at that early age gave indications of the great military talents which afterwards made him famous. He successfully repelled the attempt of his relation, Sigismund of Poland, upon the Swedish crown, and defeated his ally, the Czar of Russia. Through the mediation of England and Holland, peace was concluded on terms as honourable as they were advantageous to Gustavus. The Thirty Years' War was at this time devastating Germany. The atrocities committed by Tilly and the imperial troops upon the Protestants of Bohemia determined Gustavus to come to their rescue. His history from this time till his death on the bloody field of

Lützen, Nov. 1, 1632, is the history of Europe. His success was unchecked by a single reverse of importance; and, at Leipzig, and afterwards at the Lech, he routed the *élite* of the imperial army, and finally slew Tilly himself. Even at Lützen, where he fell (not without suspicion of murder by the hand of a near relative of his own), the Swedes drove the Austrians in route from the field, though commanded by Wallenstein, the greatest soldier of his day. Gustavus Adolphus is one of the most faultless names on the roll of kings. He was simple, wise, and brave. So long as he lived Sweden was the best governed kingdom in Europe. His military talents enabled him, while a mere youth, to beat the most skilful and practised veterans of the empire, such as Tilly, Pappenheim, and Wallenstein. In all his triumphs, however, his mind never lost its balance; nor was he ever hurried away, in the heat of passion, to the commission of any ungenerous or cruel deed. His clemency was that of a Christian, rather than a Protestant; and though he upheld and promoted the Reformed faith, he refused to steel his heart against such as preferred to walk in the old paths. His humanity was not that of the sects. The Germans, whom he had come over to assist, felt but did not lament his death. He had helped them too effectively, and restored their fortunes only too successfully. They had already begun to feel themselves too much in his debt, and had latterly received him with cold unfriendliness. But long before the war came to a close they had reason bitterly to regret the untimely end of the champion of their faith. (For the details of Gustavus Adolphus' life, see SWEDEN. For Gustavus III. and Gustavus IV. also see that same article.)

GÜSTROW, a town of Northern Germany, grand duchy of Mecklenburg-Schwerin, on the left bank of the Nebel, 20 miles S. of Rostock. It is the capital of the circle of Wenden, or old duchy of Güstrow, and the seat of a court of chancery and several government boards. Its walls have been converted into promenades, and the old castle is now used as a house of correction. The cathedral and some of the churches are handsome buildings. Güstrow is a place of some commercial importance, having several breweries, distilleries, and factories of various kinds, and some trade in corn. Pop. 9100.

GUTENBERG, or GUTTEMBERG, JOHANN (whose real name was Gensfleisch), was born at Sorgenloch, near Mentz, in 1397. It is now generally admitted that to him is due almost the entire credit of inventing the art of printing by moveable types. The respective claims of Fust, Gutenberg, and Schoeffer, are fully discussed under FUST.

Gutenberg, after a life of much suffering and hardship, died at Mentz in 1468, in great poverty. Posterity has done him the justice denied him by his contemporaries. The statue by Thorwaldsen, erected in his honour at Mentz in 1837, furnished an example which has since been followed by many towns in Germany. The Gutenberg Society keeps his name in memory by an annual festival. No books are extant that are known for certain to have been printed by Gutenberg. The famous *Mazarin Bible*, Donatus' *Grammar*, and the *Catholicon* of Janua, are believed to have issued from his press. (See PRINTING.)

GUTTA PERCHA. This valuable substance has only been known in Europe within the last twelve years. It is the concrete juice of a large tree (*Isonandra gutta*) growing in certain parts of the Malayan Archipelago—hitherto chiefly obtained from Singapore. The first specimen of the inspissated juice which appeared in England was presented to the Society of Arts in 1843, but two or three years elapsed before a just sense of the importance of the substance began to gain ground. In 1845 the importation of gutta percha into England amounted to only 20,600 lb.; in 1848 it had reached 3,000,000 lb.; in 1852 it amounted to 30,580,480 lb.—a rate of increase which gives serious cause to doubt whether the supply will long be adequate to meet the demand; for it is unfortunately the case that the trees which yield gutta percha are not only limited in their growth to certain districts, and less abundant in quantity than india-rubber trees, but they have been subjected for several years to the barbarous and wasteful mode of cutting down the trees for the sake of the sap. Whatever European industry may be able to do in checking this destructive system, and extending the cultivation of the gutta percha tree, there is yet reason to doubt whether this slow-growing tree can be reared in sufficient quantities to counterbalance the havoc already made. The *Isonandra gutta* belongs to the natural order Sapotaceæ, and is the only tree which yields gutta percha. It rises to the height of 60 or 70 feet, and the trunk is 3 or 4 feet in diameter. The tree flourishes in alluvial soils, at the foot of hills, and sometimes forms the chief part of the jungle in such situations. The foliage is of a pale green on the upper part, and covered with reddish-brown hairs beneath. The wood is soft, fibrous, spongy, pale in colour, and traversed by longitudinal receptacles or reservoirs filled with the gum, forming ebony-black lines. This gum has many of the properties of india-rubber, but it has also special properties of its own which admit of its being applied to uses for which caoutchouc is not adapted. It possesses the same indestructibility by chemical agents which makes india-rubber so valuable, and it has also the peculiarity of becoming soft and plastic on being plunged into boiling water. In this state it can be moulded into any desired form, which form it permanently retains on cooling. The great convenience and utility of such a substance could not fail to strike the natives of the countries in which it is produced; and accordingly, we find that, long before gutta percha became known to Europeans, it had been fabricated by the Malays into whips, basins, jugs, shoes, &c., thus at length exciting the attention of travellers, and leading to the introduction of some of these articles into Europe under the name of india-rubber, or, earlier still, of *mazer-wood*.

The honour of having drawn attention to its real nature and uses is due to Drs D'Almeida and W. Montgomerie. The latter, writing from Bengal, remarked on the ordinary name of the plant thus:—"The word is a pure Malayan one—*gutta* meaning the gum or concrete juice of a plant, and *percha* the particular tree from which this is procured. The *ch* is not pronounced hard like *k*; but like the *ch* in the English word *perch*." In 1843 Dr Wm. Montgomerie, of the Indian Medical Service, observing certain Malay knife and kris handles, inquired the nature of the material from which they were made; and from the crude native manufacture inferred at once the extensive uses to which the gutta percha might be put in the arts of Europe. He purchased a quantity of the raw material, sending from Singapore part of it to Bengal, and part to Europe, and suggesting some of the uses to which he thought it might be applied. The quantity sent to England secured to him at once, as the discoverer, the gold medal of the Society of Arts. The surgical uses of gutta percha were early discovered by Dr Oxley of Singapore, who declared it to be "the best and easiest substance ever discovered for the management of fractures, combining ease and comfort to the patient, and very much lessening the trouble of the surgeon."

Gutta percha arrives in lumps or blocks of several pounds' weight, but these often contain impurities, such as stones, earth, &c., introduced by the Malays for the sake of increasing the weight. The purification and preparation of this substance on a large scale are conducted as follows:—The lumps of gutta are subjected to the action of a vertical wheel, on the face of which are fixed three knives which, as the wheel revolves at the rate of 300 revolutions per minute, cut the lumps into thin slices. These are then softened in hot water, and thrown into a rotating machine, where they are further reduced by the action of jagged teeth. From this machine they again fall into water, and are further cleansed. They are then kneaded into a paste in hot water, and rolled between heated cylinders. The mass has now become uniform in texture, and is either rolled out into sheets between steel rollers, or is passed in the mass through heated iron cylinders; after which it is ready for use. Gutta percha is scarcely affected by boiling alcohol, but it dissolves nearly completely in benzine and in spirit of turpentine with the aid of heat, and also in naphtha, coal-tar, sulphuret of carbon, and in chloroform. Its solution in sulphuret of carbon or in chloroform may be almost entirely deprived of colour by filtering, the process being conducted under a glass jar, in order to prevent loss by evaporation. If this solution be exposed in a flat dish to the air, the solvent will evaporate, leaving a solid cake of white gutta percha, which retains all the properties of the common gutta; and it may be melted by a gradual increase of temperature without acquiring any perceptible colour.

The purposes to which gutta percha is applied are too numerous for recapitulation. Only a few of the more important uses can be here mentioned. It resists the action of water, and is at the same time a bad conductor of electricity; it is therefore employed for inclosing the metallic wires used in the electric telegraph. The efficiency of the submarine telegraph is largely due to this valuable substance.

Various other maritime uses have been found for it in the construction of buoys, life-boat apparatus, &c. Manufacturers and agriculturists have applied gutta percha to use in bands and straps for machinery, tubes, buckets, &c. Architects have accepted its aid in the interior ornamental work of houses, such as cornices, centres for ceilings, &c. Scientific men are aided in their electrical experiments by its high insulating power. Miners, railway officials, and others, find the value of speaking tubes made of this substance; deaf persons are also greatly benefited by its power of conducting sound. Stereotype plates have been made in gutta percha. A mould is taken by pressure of a page of type with woodcuts in gutta percha; from this mould a cast is obtained on a cylinder of gutta percha, and from this last the printing is carried on. The dentist employs gutta percha in fixing or stopping teeth. The chemist is indebted to it in the preservation and conveyance of acids which corrode glass or metallic vessels. It is also extensively used in the manufacture of waterproof clothing, waterproof shoes, &c.

Within the last few years a substitute for gutta percha has been discovered in the juice of the muddar (*Asclepias gigantea*), a common plant in India, which also affords a valuable kind of hemp. Care is required in the collection of the milky juice, on account of its exceedingly acrid nature; but when exposed to the air it hardens into a substance closely resembling gutta percha, and having many of its valuable properties. It is, however, unfitted for electrical purposes, for it is found to conduct electricity as freely as a piece of untanned hide. (C. T.)

GUTTA *Serena* (*amaurosis*), obscurity of vision depending on a morbid condition of the optic nerve—its root, its course, or its termination.

GUTTA *Trap*, a substance evidently allied to gutta percha and caoutchouc, employed at Singapore in the manufacture of bird-lime. It is the inspissated juice of an artocarpus; and it is highly probable that there are several similar vegetable productions, such as the mangegatu (*Ficus indica*), from Visagapatam, which might advantageously be introduced into commerce, and employed in the arts for purposes similar to those for which caoutchouc and gutta percha are now so extensively employed.

GUTTÆ, in *Architecture*, little conical-shaped ornaments, somewhat resembling drops; used in the Doric entablature, immediately under the triglyph and mutule.

GUTTURAL (Lat. *guttur*), a term applied to letters or sounds formed as it were in the throat.

GUTTY, in *Heraldry*, charged or sprinkled with drops.

GUY, THOMAS, the founder of Guy's Hospital in Southwark, was originally a bookseller, and afterwards a stockbroker in London. He made the bulk of his fortune by the South Sea Scheme in the memorable year 1720. He died four years later, leaving L.18,793 for the building of an hospital to be called by his name, and L.219,499 for its endowment. Guy, during his life-time, had no other reputation than that of an intensely avaricious and selfish man. He left almost all his large fortune, however, in charities, a fact which confirms, while it seems to contradict the judgment of his contemporaries.

GUY, a rope used to steady any weighty body while it is being hoisted or lowered; also, a tackle to confine a boom forward to prevent the sail from gybing. Guy likewise denotes a large rope extending from the head of the mainmast to that of the fore-mast, to sustain the tackle used for loading and unloading a ship.

GUY'S *Cliff*, in Warwickshire, a great cliff on the west side of the Avon, 1 mile N. of Warwick. Here in the time of the Saxons there was a hermitage, to which Guy, earl of Warwick, is said to have retired from the world. This hermitage was kept up till the reign of Henry VI. when Richard Beauchamp, earl of Warwick, established there a chantry, in which he erected a statue in memory of the famous Guy, at the same time raising a roof over the adjacent springs.

GUYON, MADAME, whose maiden name was Jeanne Bouvier de la Motte, was born at Montargis in 1648. She was educated successively in two of the convents of her native city. On leaving school in her twelfth year, she displayed a strong disposition to that quietism which she afterwards brought into fame and for a time into fashion. In her sixteenth year she was married to M. Guyon, a man of wealth, by whom she had five children, and who left her a widow at the age of twenty-eight. Disengaging herself from the care of her children, and thus snapping all her home-ties, she began a sort of proselytizing journey through the country, in the course of which she composed her *Moyen Court et très-facile pour l'Oraison; Le Cantique des Cantiques, interprété selon le sens Mystique;* and *Les Torrents;* works that have now indeed ceased to excite much interest, but which were at first praised and abused alternately, in terms so strong as to make their author known if not famous. Madame Guyon, having completed her "mission," returned to Paris in 1686, but her views were coldly received by the dignitaries of the church, who even thought it expedient to confine her in a convent, while her confessor, La Combe, was sent to the Bastille. The influence of Madame de Maintenon soon procured the release of the innocent and pious mystic. The first convert of note to the new gospel was Fénélon, then an abbé; but it soon came to number disciples even at the court of Louis the Great. It was vigorously opposed by Bossuet, who saw in it nothing but a revival of the gnostic heresy condemned by the church some thirteen centuries before. But it was as resolutely defended by Fénélon, who showed that Madame Guyon's views differed but little from those of St Thérèse, St François de Sales, and other mystics whom the church approved. But Bossuet had no sympathy with anything that he could not clearly and readily understand; and the beatific contemplations and holy raptures of Fénélon and Madame Guyon were in his eyes no better than flat heresy. Some extravagances committed by the more zealous of the sect determined him to crush them and their doctrines by force. Madame Guyon was arrested; and the bishops were ordered to forbid the reading of her works, which Bossuet set himself to expose and refute. Fénélon's defence of his friend in his *Maximes des Saintes*, merely aggravated her disgrace and involved himself in it. The good bishop was banished from the court, and his book sent to Rome for condemnation by the head of the church. But Bossuet's zeal overshot the mark. Many persons were disgusted with his fierce intolerance, and took part with his opponents, whom they called his victims; while the Pope himself, instead of putting the *Maximes* on the Index, merely passed upon them a censure so gentle as to be almost equivalent to an approval. On her release from the Bastille in 1701 or 1703, Madame Guyon seems to have gone into retirement with one of her sons at Diziers near Blois, where she spent the remainder of her days in the exercise of every pious and charitable act. She died June 9, 1717, at the age of sixty-nine.

Had Madame Guyon been a little more worldly-wise, she might have escaped many of the sorrows and misfortunes she had to undergo. But she often allowed her zeal to get the better of her discretion, and used language which some people called that of a fanatic, others of a madwoman. Her mental structure was singularly ill-balanced, the emotional part being developed at the expense of the purely intellectual. Her capacity of intense feeling was great, and sometimes bore her up in poetic flights of no mean aim. Witness her *Recueil de Poésies Spirituelles*, the best of which are familiar to most English readers in the exquisite translations of Cowper. This collection, however, which shows the author's strength, shows no less clearly the author's weakness. And one does not know whether to laugh or be angry, when he meets such stanzas as these:—

> Grand Dieu, pour te servir,
> Je suis dans une cage;
> Ecoute mon ramage, &c.
>
> * * * *
>
> Dieu possédant notre fond,
> Rien ici-bas ne nous touche;
> Je suis comme une souche;
> C'est lui qui vous répond!

Had the Catholic Church exhibited in Madame Guyon's case the wisdom which it generally shows in absorbing the influence of its more erratic votaries, the mystic might have been soon forgotten. But she was not only a mystic but a persecuted one, and has thus continued to enjoy a consideration greater perhaps than she deserves. There is no great harm in her writings, and her life was confessedly stainless and unimpeachable. She often in her ecstacies gives expression to ideas which might be defined as heresy, if they could be defined at all, but she never either openly attacked any dogma of the church, or proved by her daily life that she was an unworthy member of it. None of her works have any value but those already mentioned.

It is by no means proved that the *Vie de Madame Guyon, écrite par elle-même*, which was printed after her death, is entirely of her composition. It seems indeed to have been composed from different memoirs furnished by herself, first, to the official or judge of the bishop's court, Chéron, and then to the Bishop of Meaux at the time of the conferences of Issy. These materials, collected by a redacteur still more mystical than herself, appeared at Cologne, 1720, in three vols. 12mo. The verses of Madame Guyon, or at least those which are attributed to her, were collected and published at Amsterdam, 1689, in five vols. 8vo, under the title of *Recueil de Poésies Spirituelles*. This lady is also believed to have been the author of *Cantiques Spirituels, ou Emblèmes sur l'Amour divin*, in five volumes; and *La Bible traduite en Français, avec des Explications et des Réflexions qui regarde la Vie intérieure*, Cologne, 1715, in twenty vols. 8vo. Her treatise on Spiritual Torrents, after having been long circulated in manuscript, was printed, for the first time, in her *Opuscules Spirituels*, Cologne, 1704, in 12mo, with a preface describing her person. Besides these, her *Lettres Spirituelles* form four vols. in 8vo; so that her works extend in all to thirty-nine volumes, which, however, are scarcely read now-a-days. (See FÉNÉLON.)

GUYTON DE MORVEAU, BARON LOUIS BERNARD, a celebrated chemist, and an advocate of great eminence, was the son of Antoine Guyton de Morveau and Marguérite de Saulle his wife, and was born at Dijon, Jan. 4, 1737.

His father was of a respectable family, and filled the situation of professor of the civil law in the University of Dijon. He was fond of building; and from the artificers who were frequently employed about his house, young Guyton appears to have derived, almost in his infancy, a taste for mechanical pursuits, which led to an astonishing development of premature talent. For when he was only seven years old, he prevailed on his father to purchase, for his amusement, a clock which was greatly out of repair, and, as is said, he actually put it together and remedied its defects, without any assistance, so effectually, that it continued to go extremely well for fifty or sixty years afterwards. The next year he was equally successful in cleaning and repairing a watch belonging to his mother. His education was conducted in the ordinary manner at a provincial school or college, which he left at sixteen. Upon his return home he applied, for a short time, to botany, and he was soon afterwards admitted as a student of law in the University of Dijon, where he remained for three years, and then removed to Paris, in order to continue his studies at the bar. In 1756, he paid a visit to Voltaire at Ferney; and he seems to have imbibed from this personage a taste for satirical poetry, which he soon afterwards displayed, upon the occurrence of a trifling accident, in a ceremony relating to a popular Jesuit of the day. Amongst his posthumous papers, he also left some unfinished sketches of tragedies, which are said not to have been deficient in poetical merit.

At the age of twenty-four, when he had made some progress in the practice of his profession as an advocate, his father procured for him, at the price of 40,000 francs, the appointment of advocate-general of the parliament at Dijon, so that he had no further solicitude for the acquisition of an income adequate to his competent subsistence. His health was then considered as delicate; but the fears which were entertained for it proved to be completely groundless.

In January 1764, he was made an honorary member of the Academy of Sciences at Dijon, then lately established under the patronage of the Prince of Condé. This occurrence seems to have had considerable influence on the pursuits which occupied his leisure hours; and he soon became by far the most distinguished ornament of the academy which had paid him this compliment. His particular application to chemistry arose in a great measure out of an accidental emulation with Dr Chardenon, who afterwards very liberally undertook to assist him in the cultivation of this branch of science. He studied the works of Macquer and of Beaumé, and he was furnished by the latter with the materials necessary for the establishment of a small laboratory for his own use.

With regard to the more general cultivation of literature and science, he displayed considerable talent in a memoir on public instruction, together with a plan for a college, which he presented to the parliament of Burgundy, insisting, with great force and success, in opposition to Diderot, on the importance of early education in modelling the character of the human mind. About the same time he also wrote a prize essay, an Encomium on Charles V. of France, surnamed the Wise, which was afterwards inserted in the collection of his *Discourses*, published in three volumes.

In July 1767 he visited Paris with a view to the advancement of his scientific pursuits, and excited the admiration of the most celebrated chemists of the day, by the facility which he had acquired in the manipulation of his experiments. He entered, after his return, into the investigation of the great question respecting the oxidation of metals, though he did not succeed in removing the difficulties which then embarrassed it. In 1769, he pronounced, at the opening of the parliament, an elegant oration upon morals. He was soon afterwards engaged in some experiments respecting the communication of heat to different substances, the results of which, though not published, were of some importance to the theory of temperature. At the request of his friend Dr Durande, he undertook to inquire into the nature of biliary calculi, which he found to be readily soluble in ether; and it appears that a combination of ether and oil of turpentine proved of advantage to several of Dr Durande's patients, who were suffering from these concretions.

In the year 1773 he was employed in an interesting investigation of the mutual adhesion of the surfaces of solids and fluids, a class of phenomena of which the mathematical theory was never at all understood, until the publication of an essay on the Cohesion of Fluids in the *Philosophical Transactions*, soon after the beginning of this century, in which the laws of capillary action are extended to a complete analogy with all the experiments of M. de Morveau, as well as those of Taylor and Achard of a similar nature. He succeeded, about the same time, in discovering a mode of destroying the contagious vapours of pestilential diseases, by fumigation with the muriatic acid gas; he afterwards found the oxymuriatic acid, or pure chlorine, still more effectual; and it does not appear that the nitric acid, since proposed in England, has any advantages over either of these substances.

M. de Morveau's anxious desire to co-operate in the promotion of chemical knowledge induced him to make a new exertion in its favour, by undertaking, in 1776, to deliver a public and gratuitous course of lectures as a regular professor of the science, authorized by the approbation and encouragement of his brother magistrates at Dijon. He soon afterwards wrote some essays on the peculiar characters of carbonic acid; and he strenuously combated the popular prejudice which prevailed against the introduction of conductors for preserving buildings from lightning. He established a large manufactory of nitre, which was afterwards conducted by M. Courtois, the father of the famous discoverer of iodine. From chemistry he naturally diverged into the study of mineralogy; in 1777 he made a tour through the province of Burgundy, with a view to the examination of all its productions; and he actually discovered a rich lead mine, though, for want of coal, it was impossible to derive much benefit from it. He also found a white variety of the emerald in the same province, as well as some combinations of baryta, and he invented a new method of obtaining the pure baryta from its sulphate.

He had long been intimately acquainted with the Count de Buffon and with Malesherbes, both persons distinguished by elegance of taste, the one in science, the other in general literature. In 1779 and 1780 he enlarged his connections among the men of letters resident at Paris; and he was induced by Panckoucke, the bookseller, to undertake the chemical department of the *Encyclopédie Méthodique;* but it was six years before the *Dictionary of Chemistry* appeared; the articles relating to pharmacy and metallurgy were supplied by Maret and Duhamel. In the progress of this work he found himself compelled to disbelieve the existence of phlogiston as a distinct principle of inflammability, though at the beginning he had defended the doctrines of the old school. But he soon became one of the most zealous advocates of the new theory; and he contributed very much to its general introduction by the active part which he took in the arrangement of a new nomenclature. His proposals were at first thought objectionable by many of the members of the Academy of Sciences; but they soon became generally adopted throughout Europe; and the system was without doubt of great use for a time, as far as it assisted the memory and the imagination in retaining the discoveries and comprehending the theories which had so much of novelty to make them interesting. Among the original matter contained in the Dictionary, were some researches on the nature of steel, which coincided in their results with those of Monge, Vandermonde, and Berthollet, made about the same time, but published somewhat earlier. The whole volume was received in the most flattering manner by all the lovers of chemistry; but it was not till 1791 that the author's ambition was gratified by the award of the Academy of Sciences, adjudging him a prize of 2000 francs, which had been allotted to the most useful work which should appear in the course of the year. The prize, however, he begged to offer to the exigencies of the state, which were then very urgent. The Dictionary was afterwards ably continued by M. de Fourcroy.

In the meantime he condescended to appear as the translator of the *Opuscula* of Bergman, which he illustrated by notes. The example was followed by Madame Picardet, and by others of his friends, who were zealous for the promotion of science; so that the French chemists were by these means speedily made acquainted with the labours of all their contemporaries in different parts of the world. In the year 1787 M. de Morveau applied his speculations to a practical purpose, in establishing a manufactory of soda from common salt, exposed to the atmosphere, with a large proportion of lime, the soda slowly efflorescing as a carbonate. It was in the same year that, having published his *Collection of Pleadings*, he finally resigned his office at the bar, in order that the whole of his time might be devoted to the pursuit of science.

His next undertaking was of a more adventurous nature; for, in April 1784, he ascended with the President de Virly in a balloon; and he repeated the experiment in the month of June, hoping to be able to direct his aërial course at pleasure. The balloon appears to have been about 30 feet in diameter; and, when we consider the action of the wind upon a surface of such extent, we must be aware that every attempt to oppose or modify it must have been perfectly futile. He was visited soon afterwards by the ingenious and lamented Mr Tennant, who went to Dijon purposely to become acquainted with him, and who had an opportunity of performing some original experiments in his laboratory. He was made a member of the Royal Academy of Medicine at Paris in 1786, as a compliment to the merits of his labours for the preservation of the public health. He received a visit, in the succeeding year, at once from Lavoisier, Berthollet, and Fourcroy, together with Monge and Vandermonde; and our countryman, Dr Beddoes, who was then travelling in France, had the good fortune to join this interesting party, all of them deeply engaged in the discussion of the great chemical questions which were then undecided. In April 1788, M. de Morveau was placed on the list of the foreign members of the Royal Society of London; and the same mark of respect was also paid him at different times by almost all the scientific societies of Europe.

In September 1791 he was unfortunately elected a member of the Legislative Body; and having also been made solicitor-general of his department, he could no longer continue the chemical lectures which he had delivered without intermission for fifteen years, and he resigned his chair to Dr Chausier. It must not be omitted by an impartial biographer, that, on the 16th of January 1793, he thought himself compelled to vote with the majority, for the death of the king; and it is a poor compensation for this fatal error that, in the same year, he resigned a pension of two thousand francs a year, in favour of that republic to which he had already sacrificed the best feelings of humanity. He afterwards became a commissary of the assembly and was attached to the army of the Netherlands. In this capacity, besides many other instances of personal courage, he is said to have rendered essential service to his countrymen, by the construction of a balloon, in which he ascended, together with some of the staff of General Jourdan, in order to observe the motions of the enemy during the battle of Fleurus. After his return to Paris he was appointed professor of chemistry in the *Ecole Polytechnique*, and he was an effective co-operator in the first establishment of that useful institution. In 1795 he was again chosen a member of the Council of Five Hundred; and he was appointed by the government one of the forty-eight members of the National Institute, then recently embodied. He had for some time been a correspondent, but was never a member, of the Academy of Sciences. His political engagements terminated in 1797, when he resolved once more to devote himself exclusively to science. In 1798, he fulfilled the duties of director of the *Ecole Polytechnique* during the absence of Monge, who was in Egypt, and for whom he insisted that the salary should be reserved. The following year, Bonaparte, then first consul, made him a general administrator of the mint. He received the cross of the Legion of Honour in 1803, and obtained, two years afterwards, still higher rank in the order, particularly as an acknowledgment for the public benefits which had been derived from his methods of fumigation. In 1811 he was elevated to the dignity of a baron of the French empire.

From 1798 to 1813, he continued his labours as professor of chemistry in the Polytechnic School; he then obtained leave to retire, but he survived only a few years, and died of a paralytic affection, or rather of a total decay of strength, the 21st of December 1815, at a period when the political changes in the kingdom would have exposed him to annoyances and perhaps hardships, which would have been very severely felt at so advanced an age. In stature he was rather below than above the middle size; his conversation was animated and copious, his manners courteous and obliging; he was full of anecdote, and always ready to communicate whatever information he possessed. He married, late in life, Madame Picardet, the widow of an academician of Dijon, whose tastes and pursuits were congenial with his own, and who had distinguished herself by translating several works of science and of literature from the different languages of the north of Europe. As to his numerous publications, a bare catalogue of these will be amply sufficient to show the extent of his researches and the variety of his pursuits. It is the more necessary to do justice to his diligence and perseverance, as we cannot easily point out any one important discovery or invention that can be considered as commensurate with the high promise of his early infancy. The article ACID of the *Dictionary*, and the *Methodical Nomenclature*, must be ranked as the best of his productions; but the character of both these is rather useful than splendid.

GWALIOR, a strong and very celebrated fortress of Hindustan, in the dominions of Scindia, in an elevated situation on a hill, one mile and a half in length, but in few places exceeding 300 yards in breadth. At the north end the sides are so steep as to be nearly perpendicular, and its height is 342 feet. It has several reservoirs of good water, and a small river runs close past it. A stone parapet extends all round the slope of the hill, behind which are collected piles of round stones, which form an excellent defence, and it was judged unassailable until it was stormed in 1780 by Major Popham. The town, which stands at the bottom of the hill, is large and populous, and contains many good houses of stone, which is furnished in abundance by the neighbouring hills, that form an amphitheatre round the town and fort at the distance of from one to four miles. The town carries on an extensive trade with the Mahratta and British territories, and derives also considerable benefit from the Mohammedan pilgrims, who visit the tomb of Ghose al Alum, a celebrated religious person, who is interred within the fort. Gwalior is of such antiquity that its origin is lost in remote tradition. It must have been at all times a military post of great consequence, both from its central situation, and its peculiar position, which in the estimation of the natives rendered it impregnable. It is first mentioned in authentic history in the year 1023, when it was summoned by Sultan Mahmoud of Ghizni. It was taken by the Mohammedans in the year 1194, and was used as a state prison, in which several princes met their death from opium or the dagger. On the decline of the Mogul empire, it was taken by the Mahrattas, and afterwards by the British, as mentioned above, in 1780. It was subsequently taken possession of by Scindia; and during the war of 1804 it again surrendered to the British troops after a breach was made in the walls. It was not, however, taken possession of by them, and by the treaty with Scindia in 1805 it was ceded to that chief. Finally, in January 1844, after the battle of Maharajpoor, it was occupied by the Gwalior contingent, a military force commanded by British officers, and thus may be regarded as having been virtually placed within the power of the British government. The Gwalior territories, or the possessions of the family of Scindia, of which this town forms the capital, have a singularly irregular outline, and consist of several detached districts, the principal of which is bounded on the N.E. by the Chumbul, dividing it from the British districts of Agra and Etawah. The area of the whole territory extends over 33,119 square miles, and supports a population of upwards of three millions. The founder of the ruling family was Ranojee Scindia, who, from an humble station in the service of the Peishwa, rose to distinction and power, and became a chief of considerable importance. He was succeeded in 1750 by his natural son Madhajee Scindia, whose earlier feats in arms gave little promise of his future military successes. At the great battle of Paniput in 1761 his followers with difficulty escaped the general carnage, and their leader received a desperate wound which rendered him lame for life. From this period, however, his fortunes appear in the ascendant, and the growth of his power is thus described by Sir John Malcolm:—"Madhajee Scindia took full advantage of the dissensions that occurred at Poona, after the death of Ballajee (1761), to usurp as far as he could the rights and lands of the head of the empire to the north of the Nerbudda. The detail of the progress of this system of spoliation of both friend and foe is not necessary; suffice it to say, this able chief was the principal opposer of the English in the war they carried on in favour of Ragobah. He was the nominal slave, but the rigid master of the unfortunate Shah Allum, emperor of Delhi—the pretended friend, but the designing rival of the house of Holkar—the professed inferior in all matters of form, but the real superior and oppressor of the Rajpoot princes of Central India; and the proclaimed soldier, but the actual plunderer of the family of the Peishwa." In 1782 the British government recognized Madhajee as an independent sovereign; and at the period of his death in 1794, his dominions extended from the River Taptee on the S. to the northern limit of the district of Delhi, and from the Gulf of Cambay on the W. to the Ganges in the E., including Candeish, a portion of the Deccan, the greatest part of Malwa, the districts of Agra and Delhi, and the central and finest part of the Doab. He was succeeded in his possessions by his grand-nephew Dowlut Rao Scindia, then in the fifteenth year of his age. Dowlut Rao, joining his forces with those of the Rajah of Berar, the allied chiefs in 1803 invaded the territory of the Nizam, which was under the protection of the East India Company, and on the 23d September in that year the Mahratta army was surprised at Assye by a British force commanded by General Sir Arthur Wellesley, subsequently the illustrious Duke of Wellington, and after a prolonged and fiercely contested battle, was totally defeated. The overthrow of Scindia's military resources was completed by the subsequent defeat which the confederated Mahrattas received from Sir Arthur Wellesley at Argum, in Berar, and from Lord Lake at Allyghur, Delhi, and Laswaree, in

Northern Hindustan. At the close of the year 1803, Dowlut Rao acceded to a treaty dictated by the British government, ceding, on the left bank of the Jumna, all his forts, territories, and rights in the Doab; and on the right bank of the river, all his forts, territories, rights, and interests in the countries which are to the northward of those of the rajahs of Jeypore and Joudpore. Mugut Rao, the successor of Dowlut Rao Scindia, dying childless in 1843, was succeeded by Ali Jah Jyajee Scindia, who being a minor, the widow of the deceased prince became regent. A period of anarchy ensued, and disturbances took place, which, extending rapidly towards the adjacent territories, compelled the British government to resort to arms for the purpose of obtaining security for the future tranquility of the common frontier. On the 21st December 1843 the British army, led by Sir Hugh Gough, commander-in-chief, accompanied by Lord Ellenborough, governor-general, commenced crossing the Chumbul, near the town of Dholpore, and on the 29th came in front of the Mahratta army about 15 miles north-east of Gwalior, and in a position supported by the neighbouring villages of Maharajpoor and Chonda. After an obstinate engagement, in which the British suffered very severe loss from the well-served artillery directed against them, the Mahrattas were dislodged from all points of their position, and the survivors of the carnage retreated to Gwalior, having lost 56 pieces of artillery, and all their ammunition waggons. The total loss on the side of the British was 106 killed, 684 wounded, and 7 missing. The numbers engaged were nearly equal—about 14,000 on each side. Simultaneous with the march of the commander-in-chief from Dholpore was that of Major-General Grey with an army of about 8000 or 9000 men from Bundlecund. Crossing the River Sinde at Chandpore, this force marched to Puniaur, 12 miles S.W. of Gwalior, and there, on the same day, encountered a Mahratta army estimated at 12,000 strong, with 24 guns. The Mahrattas, after a severe struggle, were defeated with the loss of all their artillery, and a great number of men. The loss on the part of the British was 25 killed and 189 wounded. Shortly after a treaty was concluded, the main provisions of which related to the sequestration of a portion of Scindia's dominions for the maintenance of a contingent force, to be commanded by British officers, for the protection of the Gwalior territories. The young Rajah having attained his majority, assumed the reins of government in 1853. The town of Gwalior is in N. Lat. 26. 13., E. Long. 78. 15.

GYBING, the shifting of the boom of a fore-and-aft sail from one side of the mast to the other, either to alter the course of the vessel suddenly, or to accommodate the sail to a change of wind.

GYGES. See CANDAULES.

GYMNASIUM, in *Antiquity*, the name given to any place set apart for healthful or invigorating physical exercises. The gymnasium took its name from the fact that such as frequented it exercised either naked (γυμνοί) or clad only in a light tunic. The Greeks and Romans both attached much importance to the gymnasia, which formed an integral part of their systems of education; and the Greeks bestowed more time and attention on the gymnastic training of their youth than on all the other departments put together. There was no such thing as a Greek city of any size or importance which did not boast at least one gymnasium. Athens had three great public gymnasia—the Academia, Lyceum, and Cynosarges, besides numerous private ones on a smaller scale. Solon considered these institutions of so much importance as to draw up a special code of laws for their management. Their administration was entrusted to a gymnasiarch, whose duties were to watch and control the youth, place them under proper teachers, conduct the periodical games and festivals, and pay the athletes whom he trained for them. In Athens the number of gymnasiarchs appears to have been ten, but it is not known how they took duty, whether in rotation or otherwise. Inferior in station, but not in real importance to the gymnasiarchs, were the "Sophronistæ," or *teachers of wisdom*, who seem, however, to have watched over the moral rather than the physical development of the youth during their attendance at the gymnasium. Their number, like that of the gymnasiarchs, seems to have been also ten. Next in rank to them came the gymnastæ and pædotribæ, who had all the practical part of the teaching to do, and who assigned to the youth kinds of exercise adapted to the physical capabilities of each, which it was part of their business to study and know. The officers whose duty it was to prepare the youth for the day's exercise by anointing them with oil and then besprinkling them with dust, were called "aliptæ," or anointers. The exercises taught appear to have been pretty much the same over the whole of Greece, though they seem to have been carried out with somewhat different views. Thus the Spartans looked on them rather as a sort of initiation into the sterner realities of warfare, while the Athenians not only made them subserve this end, but also used them as a means for imparting grace to the action and movement of the limbs. The chief games of the gymnasium were foot races, jumping, leaping, quoits, wrestling, boxing, dancing, the pancratium, &c., while the younger pupils practised also with balls, tops, and a variety of other games similar to those in vogue among the youth of modern times.

Remains of gymnasia have been unearthed at Naples, Ephesus, and many other cities. From these, Vitruvius reconstructed his plan of the gymnasium, of which an engraving will be found in Newton's translation of that writer's works.

From these descriptions we learn that the Gymnasia were not single edifices, but a group of buildings capacious enough to contain many thousands of people, and consisting of twelve different parts, viz.—1. The exterior porticoes, where the philosophers, rhetoricians, mathematicians, physicians, and other virtuosi, read public lectures, and where they also disputed and rehearsed their performances; 2. The *ephebeum*, where the youth assembled very early, to learn their exercises in private, without any spectators; 3. The *coryceum*, *apodyterion*, or *gymnasterion*, a kind of ante-chamber, where they stripped, either to bathe or exercise; 4. The *elæothesium*, *alipterion*, or *unctuarium*, appointed for the anointings, which either preceded or followed the use of the bath, wrestling, pancratia, &c.; 5. The *conisterium*, or *conistra*, in which they covered themselves with sand or dust to dry up the oil or sweat; 6. The *palæstra*, properly so called, where they practised wrestling, boxing, pancratia, and other exercises; 7. The *sphæristerion* or tennis-court, reserved for exercises in which balls were used; 8. Large unpaved alleys, which comprehended the space between the porticoes and the walls with which the edifice was surrounded; 9. The *xysti*, or porticoes for the wrestlers in winter or bad weather; 10. Other *xysti* or open alleys, allotted for summer and fine weather, some of which were quite open, and others planted with trees; 11. The baths, consisting of several different apartments; and, 12. The *stadium*, a large space of a semicircular form, covered with sand, and surrounded with seats for the spectators.

GYMNASIUM, in its modern use, sometimes signifies a school for gymnastic exercises; but on the Continent, particularly in Prussia, the higher schools, intended to give immediate preparation for the universities, are called gymnasia.

GYMNASTICS, in the general acceptation of the term, denotes every exercise which tends to develope and invigorate the bodily powers; such as walking, running, riding, fencing, rowing, skating, dancing, and many others. In a narrower sense gymnastics includes those manly and healthful games which have been encouraged by all high-minded nations as calculated to improve the physical strength, and to keep alive the martial spirit of their inhabitants. In a yet more limited sense, the term gymnastics has been employed to denote that modern system of bodily exercises, some account of which will be given in this article.

The elements of a system of gymnastics are to be found in most nations from the earliest times. In the infancy of society, when the individual was valued according to his personal strength and prowess, it was only natural that the utmost care should be bestowed on those arts which most surely led to distinction. All education then consisted chiefly in the practice of such exercises as were best calculated to develop muscular strength, and make the tenure of life as secure as possible. Thus the first gymnastic exercises, both of those nations that have reached the highest civilization, and of those that are now dying out in their primitive barbarism, were the same, viz., running, leaping, swimming, and the throwing of missiles. These exercises were at a very remote period systematized and reduced to a science by the Greeks in the manner described in the article GYMNASIUM.

With the invention of gunpowder gymnastic exercises began to be neglected. Rosseau in his *Emile* was the first to call attention to the injurious consequences of such indifference; and it is in a large measure to his eloquent appeals that gymnastics have in recent times been made to constitute an integral part of school education. The good effects of this innovation have in no country been more strikingly exemplified than in Germany. When many parts of that country groaned under the iron yoke of Napoleon, Jahn and his followers, encouraged by the Prussian minister Stein, were establishing *turn-plätze* or gymnastic schools, from which issued the well-trained youth who in due time drove the French legions across the Rhine.

The propriety of employing training to develop the powers of the body is now almost as readily acknowledged in most countries as the necessity of education to cultivate the faculties of the mind. But nothing is privileged from abuse; and empiricism, which has brought so many other things into disrepute, has unluckily fastened upon gymnastics. In the *Encyclopédie Moderne* we find the subject divided into—1. *Gymnastique civile et industrielle*; 2. *Gymnastique militaire, terrestre et maritime*; 3. *Gymnastique médicale*; and, 4. *Gymnastique scénique ou funambulique.* Nor is this all. Each of these divisions is subdivided into four or five branches, as if the subject, forsooth, admitted of the most systematic arrangement. Thus, under the head of *Gymastique médicale*, are included, first, *Gymnastique hygiénique, ou prophylactique, pour conserver une santé robuste*; secondly, *Gymnastique thérapeutique, pour le traitement des maladies*; thirdly, *Gymnastique analeptique, ou des convalescens*; fourthly, *Gymnastique orthopédique, qui a pour but la guerison des déformités.* This affectation of method is exceedingly absurd, inasmuch as it confounds with the exercises themselves certain hypothetical uses, and assumes as the very basis of the classification results which have not been satisfactorily ascertained. But however this may be, the importance of gymnastics, in another point of view, cannot possibly be disputed. If persevered in, they are calculated to develop every muscle of the trunk, arms, and legs, to its utmost extent; they give the student the most perfect command of his whole bodily frame; they are the best preparatives for the elegant and manly accomplishment of fencing; and they afford excellent training for the amateurs of running, leaping, wrestling, and sparring. Nor are the advantages derived from such exercises confined to the soldier or the sailor; their usefulness is experienced in many other situations of life. But their importance can only be fully known when we are called upon in emergencies of unexpected danger—amidst fire, shipwreck, the destruction of bridges, or the fall of buildings—to evince the superiority resulting from that presence of mind and fertility of resources which are conferred by the consciousness of physical strength and nerve, and by the habit of acting and moving where other men would be instantly paralysed. Lastly, clear heads and light hearts, the natural concomitants of health, are the rewards of a judicious and moderate prosecution of gymnastics.

The elementary exercises in gymnastics are performed by means of the horizontal pole, the parallel bars, the masts or poles, the ropes, the triangle and trapezium, the ladder, the wooden horse, the inclined plane, and the flying course or giant's steps. The pupils, after being prepared by a course of comparatively gentle but active exertion, proceed to take lessons on the *horizontal pole*; the principal use of which is to develop the strength of the hands and arms, though many other exercises are performed on it. The *parallel bars* are usually made circular, and vary from six to eight feet in length, and from three to four inches in diameter; they are fixed about two feet apart, and placed at a height of from three to four feet from the ground. Captain Clias gives sixteen movements in this apparatus, and Colonel Amoros thirty-eight; but it is obvious that the lessons are susceptible of great variety, and that the interest may be increased by fixing the bars occasionally at the height of six or seven feet from the ground. The exercises on the *masts* or *poles* are varied by the latter being placed in different positions, either vertically or angularly, and by the introduction of rope-ladders or knotted ropes. The *ropes* are used sometimes plain, sometimes with large knots in them, and sometimes with a bar across. They are placed vertically, horizontally, and angularly, to give variety to the exercises, which is also increased by loosening and tightening them. The *triangle* and *trapezium* are two of the most amusing instruments in modern gymnasiums; and, from the lightness of their construction, and their being constantly in motion, give an appearance of ease and grace to all the evolutions performed on them. The invention of the triangle has been claimed by Captain Clias, though of right it belongs to the mountebanks of Italy, who employed it to amuse the public long before this celebrated gymnast was heard of; the trapezium owes its origin, or at least its introduction into the schools, to Colonel Amoros. The *wooden ladder* is usually fixed firmly between two walls, with the lower end just high enough for the pupils to reach it with both hands. Sometimes it is also placed perpendicularly with one end resting on the ground; but the exercises admit of more variety when it is placed in the position first described. The distance between the bars in the perpendicular ladder is commonly from eight to twelve inches; but when its position is inclined, the spaces should always be wide enough to admit of the pupil passing easily through them. The *rope ladder* is susceptible of still greater variety of position, and the bars are usually placed closer together, as few movements beyond the different modes of ascending and descending are practised upon them. The *wooden horse* is for exercise in vaulting and leaping, and may be raised or lowered upon its stand so as to suit the progress of the different classes. The *inclined plane* is ordinarily a deal plank of 25 or 30 feet in length, and about 2 feet in breadth; it admits of some highly useful exercises, tending to strengthen the hands, arms, chest, abdomen, legs, and feet. The *flying course*, or *giant's steps*, is an amusing exercise, but affords no advantages which are not attained by the apparatus already described. For the detail of the exercises performed, with figures illustrative of the different positions, we refer to the works of Clias, Amoros, and Roland.

Almost all the advantages which are generally supposed to result from gymnastic exercises, may be attained by the practice of our own national games, which, if not in every case British in their origin, are peculiarly so by their adoption and continued improvement. They merit notice, therefore, first, by reason of their nationality, and because, for the most part, they require in an eminent degree the union of strength, perseverance, and courage. 1st, *Wrestling*, though conspicuously introduced into all foreign works on the present system of gymnastics, is little more than theoretically known on the Continent; whereas, in some of the English counties, the practical wrestlers are unrivalled. We therefore claim this as one of our national games, and venture to affirm that its champions will not hesitate to enter into competition with any foreign gymnasium. 2d, *Boxing* is an exercise which brings the body into active and healthy exertion, increasing the elasticity of the limbs, improving the play of the lungs, and giving great firmness on the legs and power to the arms. Quickness of eye, and accuracy in measuring distances, are also acquired by the practice of boxing; by which, be it observed, we mean *sparring*, as practised by gentlemen, that graceful imitation battle, which differs as widely from the brutalizing exhibitions of prize-fighting, as the *cestus* with which Dares dashed out the teeth of Entellus differs from the well-stuffed gloves of a modern master. 3d, *Riding*, *walking*, and *running*, are exercises requiring strength, perseverance, and activity; and, as a nation, our recorded equestrian and pedestrian feats may challenge Europe. We have, indeed, heard of three Frenchmen, Gervois, Labat, and Stumon, who are said to have run a French league in ten minutes, an exploit which surpasses anything in our sporting annals; but the story is too improbable to be admitted without strong confirmation. 4th, *Archery*, one of our most ancient and manly recreations, is still kept up in many parts of England and Scotland; and although its champions would no doubt cut but a sorry figure in competition with the Lockesley of Ivanhoe, or even with him whose grandsire " drew a good bow at Hastings," yet the spirit of emulation has produced no mean degree of excellence in this graceful and healthy exercise. 5th, *Cricket* is so indisputably our own, that nothing need be said upon the subject, except that it is yearly becoming a greater favourite in Scotland, where formerly it was seldom played. 6th, *Singlestick* has now but a small number of admirers, and its professors are of course still more limited. 7th, *Putting the stone, and throwing the hammer*, fall more appropriately under the head of Scottish gymnastics. In the Highlands of Scotland there are instances of celebrity in throwing the hammer descending from father to son for generations, as a family characteristic. This is most graphically described in the account given by Sir Walter Scott of the contest between Norman nan Ord and Hal o' Wynd, who is represented as a perfect prince amongst the gymnasts of an age when such accomplishments were in the highest repute. It may be added that at the present day the Scottish national games are kept up with great spirit, and that clubs have been instituted in various parts of the country, for the purpose of encouraging them, by awarding medals, and other honorary distinctions, to such as excel in these pastimes. (J. B—E.)

GYMNOSOPHISTS, an appellation bestowed by the Greeks on the Indian philosophers in ancient times, because, according to tradition, they went naked, or nearly so. They were also called Βραχμαναί, that is, Brachmans or Brahmins. (See BRAHMINS, vol. v., p. 271.) They were of two parties, Indian and Ethiopian. The former dwelt in the woods, where they lived on the wild products of the earth. The Ethiopian Gymnosophists are said to have discharged the sacred functions in the manner of the Egyptian priests, and had colleges and disciples of different classes. The Gymnosophists were remarkable for their contempt of death, and are said to have practised suicide in the most deliberate manner, by casting themselves into the flames. It is probable, however, that this was an act of devotion with a view to merit immortality. In this way did Calanus sacrifice himself in the presence of Alexander the Great; and likewise did Xarimarus at Athens when Augustus was there. The little acquaintance of the ancients with the Indies gave rise to many wonderful stories respecting the Gymnosophists. They appear in general to have been wise and learned men, to judge from their maxims and discourses as recorded by historians. They kept up the dignity of their character to such a degree that they maintained an independent position even in the courts of their princes. They maintained the immortality and transmigration of the soul, and placed the chief happiness of man in a contempt of the gifts of fortune and of the pleasures of sense.

GYMNOTUS, a genus of fishes, of which one species is the electric eel. See index to ICHTHYOLOGY, and ELECTRICITY.

GYNÆCEUM, among the ancient Greeks, denoted the apartment of the women (always in the innermost part of the house), where they employed themselves in spinning, weaving, and needlework. At Rome, under the emperors, there was a particular establishment of gynæcea, which were a kind of manufactories in which women were employed to make clothes and furniture for the imperial household. Hence the term has sometimes been applied in modern times to silk factories and others where females are associated in considerable numbers.

GYONGYOS, a market-town of Hungary, county of Hevcs, at the foot of Mount Matra, 44 miles N.E. of Pesth. It has four Roman Catholic churches, a Franciscan monastery, and a gymnasium; manufactures of woollen cloth, leather, hats, brandy, &c., and an active trade in cattle and agricultural produce. Good wine is produced in the vicinity. Pop. 15,000.

GYPSIES, or GIPSIES, a remarkable race of Asiatic origin, found in almost every country of Europe, in most parts of Asia, and in the interior of Africa, and characterized for the most part by their vagabond course of life. The word *gypsy* is a corruption of *E-gypti-an*—the common designation of the vagrant race in old English statutes, in accordance with this prevalent belief, founded on their own assertion, that they came from Egypt. Their first appearance in Europe was about the year 1417; and though all evidence is opposed to their being of an Egyptian stock, it seems not improbable that some at least of this scattered race may have sojourned for a time in Egypt in their migration from the East. A very circumstantial and elaborate account of this singular race is given by Grellmann, in his *Histor. Versuch über die Zigeuner*, which has been translated into English by Mr Raper, under the title of *Dissertation on the Gipsies*, Lond. 1787, 4to. " The Egyptian descent of these people," says Grellmann, " is not only destitute of proofs, but the most positive evidence is found to contradict it. Their language differs entirely from the Coptic; and their customs are very different from those of the Egyptians. They are indeed to be found in Egypt; but they wander about there as strangers, and form a distinct people, as in other countries." He afterwards proceeds to show that they are sprung from the lowest class of Indians, namely, the degraded Pariahs; or, as they are called in Hindustan, *Sudras*. The emigration from their country he conjectures, with much apparent probability, to have been occasioned by the devastating expedition of Timour Beg, in the years 1408–9, when that savage conqueror ravaged India, destroying all who offered resistance to his arms; while those who fell into the enemy's hands were made slaves, of whom, however, 100,000 were put to death. In the universal panic occasioned by these cruelties, it is conjectured that a large number of the terrified inhabitants saved themselves by flight; but at this point Grellmann frankly acknowledges that he is unable to trace the route by which the fugitives passed from Hindustan to Europe.

The gypsies are variously designated in different countries: thus, in France they are called *Bohémiens*, as coming thither from Bohemia; in Spain, *Gitanos*—a designation expressive of their crafty character; in Portugal, *Ciganos*; in Germany, *Zigeuner*; by the Italians, the *Walachians*; and the Turks, *Zingari*, *Zigani*, or *Zingani*, and *Chinganéh*. These various appellations would appear to have, for the most part, a common origin; and this perhaps is to be found in the word *Tchingani*, the name of a tribe met with by Lieutenant Pottinger in Beloochistan, near the mouth of the Indus, and who are described as resembling the gypsies in many of their peculiar customs. The gypsies, too, call themselves *Pharaôn* or *Sinte*, which corresponds to *Sinde*, the Hindu name for the inhabitants of Hindustan.

The language of the gypsies, though a kind of lingua-franca, being formed out of fragments and corruptions of many tongues, has, nevertheless, a marked oriental cast. Most of the words are of Indian origin, and are found, in part, with little variation, in the Sanscrit, the Malabar, and the Bengal languages; and many words have been adopted from the different nations among whom they sojourn. Bishop Heber relates that he met with a camp of gypsies on the banks of the Ganges, who spoke the Hindu language as their mother tongue; and he also found the same people in Persia and Russia. Their persons and customs also bear a striking resemblance to those of the Hindus.

There can scarcely be a doubt that at one period a very considerable number of the gypsy race passed into Europe from Egypt; and, indeed, history informs us that when the Sultan Selim conquered Egypt, A.D. 1517, many of the inhabitants refused to submit to the Turkish yoke, and revolted under one Zinganeus (whence their Turkish appellation of *Zingani*); and being at length subdued and banished, they agreed to disperse in numerous small parties over different countries, where their supposed skill in the black art procured them a favourable reception in that age of general superstition. Their numbers were quickly multiplied by the accession of persons who imitated their language, manners, and complexion, and betook themselves to the practise of chiromancy, begging, and pilfering, so that the gypsy race came to be regarded as a nuisance in most of the states of Europe. Accordingly, they were expelled from France in the year 1560, and from Spain in 1591. But in 1531 they are described by statute 22d Henry VIII., c. 10, as "an outlandish people calling themselves Egyptians, using no craft nor feat of merchandise, who have come into this realm, and gone from shire to shire, and place to place, in great companies, and used great, subtle, and crafty means to deceive the people; bearing them in hand that they by palmistry could tell men's and women's fortunes; and so many times by craft and subtility have deceived the people of their money, and also have committed many heinous felonies and robberies." They are, therefore, directed to avoid the realm, and not to return under pain of imprisonment, and forfeiture of their goods and chattels; and it is further declared, that upon their trials for any felony which they may have committed, they shall not be entitled to a jury *de medietate linguæ*. It was afterwards enacted, by statutes 1st and 2d Philip and Mary, c. 4, and 5th Eliz. c. 20, that if any such persons shall be imported into the kingdom, the importer shall forfeit L.40. And if the Egyptians themselves remain one month in the kingdom, or if any person being fourteen years old, whether natural-born subject or stranger, who has been seen or found in the fellowship of such Egyptians, or having disguised him or herself like them, shall remain in the same one month at one or several times, it is felony without benefit of clergy. Sir Matthew Hale tells us that on one occasion at the Suffolk assizes, no less than thirteen persons were executed upon these statutes a few years before the Restoration. These are the latest instances of condemnation under these statutes; yet the last sanguinary act itself was not repealed till 23d Geo. III., c. 54.

In Scotland the gypsy tribe seem to have enjoyed some share of indulgence; for a writ of privy seal, dated 1594, supports John Faw, lord and earl of Little Egypt, in the execution of justice on his company and folk, conform to the laws of Egypt, and in punishing certain persons therein named, who had rebelled, robbed him, absconded, and refused to return home. James's subjects are commanded to assist in apprehending the fugitives, and in assisting Faw and his adherents to return to Egypt. There is another writ in his favour from Mary Queen of Scots, 1553; and in 1554 he obtained a pardon for the murder of Nunan Small; so that it appears he had remained long in Scotland, and perhaps spent some time in England. From him this kind of strolling people received in Scotland the name of the *Faw Gang*.

In the reigns of Henry VIII. and Elizabeth, the gypsy tribe were marked out for general persecution in England; yet their numbers do not appear to have diminished greatly in consequence. They are spread over all Europe; and about the year 1830, their total number was estimated at about three quarters of a million. It is in the south of Spain, however, that these strolling people appear in greatest numbers. They are also numerous in Hungary, Transylvania, and Moldavia; and are found in still greater numbers in Bessarabia, near Constantinople, and throughout Turkey. For nearly four centuries have these people wandered through the world; and in every region, and among every people, whether barbarous or civilized, they have continued equally unchanged by the lapse of time, the variety of climate, or the force of example. Their singular physiognomy, and their peculiar manners, are the same in every country; their complexion receives no darker shade from the burning sun of Africa, nor any fairer tincture from the temperate climes of Europe. As to religion they have none; though from motives of policy they generally profess the established faith of the country in which they live. Many attempts have been made to educate and civilize them; but they seem singularly unsusceptible of religious impressions. In the neighbourhood of civilized life they continue barbarous; are content to live in tents or in holes in the earth, and wander in companies from place to place as fugitives and vagabonds. In Transylvania the gypsies have a form of constitution, being in a manner governed by chiefs, whom they distinguish by the Sclavonian title of *waywode*. To this dignity every one is eligible who is of a family descended from a former waywode; but the preference is usually given to those who have the most wealth, or who are of a large stature, and not past the meridian of life.

In appearance, the gypsies are of a brownish or olive complexion, with jet black hair and dark eyes, and very white teeth. In Spain many of the gypsy girls are considered beauties,—a fact dependent not a little, it is probable, on the intermixture of Spanish blood. They are also noted for the symmetry of their limbs, which distinguishes even the men, whose general appearance, however, is shy and repulsive. Seldom tall or powerful in frame, they possess much elasticity and activity, and their physiognomy denotes carelessness and levity. In mild climates they dispense with tents, and congregate in companies in forests and deserts. In cold countries they find shelter in caves, or build huts sunk in the earth, and cover them with sods laid on poles. In Spain, and also in Hungary and Transylvania, there are some gypsies who follow trades. They are innkeepers, farriers, and dealers in horses; smiths, nail-makers, tinkers, and menders of old pots and kettles; makers of wooden spoons, spindles, &c.; and occasionally they engage in the labours of the field. They have a certain degree of natural talent for music, and are often respectable performers on the violin, flute, Jew's-harp, &c. Their skill in this art is confined to instrumental music, particularly of the dance kind. In many places the gypsies support themselves by rope-dancing and tricks of legerdemain; while the women find occupation in fortune-telling, the interpretation of dreams, and the like. In the earlier part of life, particularly in Spain, the women are dancers; and when they grow older, they invariably practise fortune-telling and chiromancy. In warm countries the gypsy children go perfectly naked for the first few years of their life, yet are objects of much solicitude to their parents, by whom they are carefully instructed in lying, thieving, and all kinds of knavery, and regarded with a degree of blind affection that seems to border on animal instinct. The gypsies have a passion for rings, trinkets, and all kinds of ornaments, and frequently adorn themselves in the most heterogeneous fashion. In England the females are generally distinguished by a cloak, gray or red, and a coloured kerchief tied around the head. Their domestic utensils are few, consisting usually of a pan, a dish, a kettle, and a silver cup. They frequently possess horses and pigs; and in England every gypsy company has one donkey or more for the conveyance of their effects. The gypsies, like the Pariahs, are very disgusting in many of their customs; such as, for instance, that of eating the flesh of animals that have died of disease. A murrain, accordingly, is to them a welcome event. They are fond of brandy; and both sexes are excessively addicted to the use of tobacco, which they regard as a luxury to be obtained at almost any sacrifice. There is no species of roguery they will not practise in order to obtain money: for instance, it is a common trick among the Transylvanian gypsies to have their children baptized repeatedly, at different places, for the sake of the present usually bestowed by the godfather on such occasions on the poor parents of the child. They marry very early: boys of fourteen and girls of twelve are often man and wife; nor is the closest propinquity any bar to their union. But in these matches the wily gypsy carefully avoids the legal forms that might prevent a separation in case he should tire of his mate—a thing of very common occurrence. They never marry any but of their own race. Such is their natural depravity, that they have a real enjoyment in cruelty; so that they were formerly employed in preference as executioners. At the same time their cowardice is notorious. They have occasionally been taken into the armies in Hungary and Transylvania, but have always been themselves very indifferent soldiers.

Besides Grellmann's work already cited, the reader may consult with advantage Mr Marsden's paper on the Gypsy Language, in vol. vii. of the *Archæologia;* Captain Richardson's paper on the Natas, in vol. vii. of the *Asiatic Researches;* Bischoff's *Deutsch-Zigeunerisches Wörterbuch*, of which the preface contains an excellent summary of the history and present state of this singular people; Hoyland's *Historical Survey of the Gypsies;* see also the graphic descriptions of gypsy life, as contained in Scott's *Guy Mannering*, and in Borrow's *Gypsies in Spain.*

GYPSUM, or SULPHATE OF LIME (γύψος of the Greeks; *Gypsum* of Pliny and Vitruvius), is an abundant mineral, in some of its forms, in many countries. It is known in Britain and other places by the name of *alabaster;* but this designation is also applied to a granular carbonate of lime, seemingly deposited from water, which, by way of distinction, is named *oriental alabaster*. The ἀλάβαστρον of the ancient Greeks, however, and the *alabastrum* of the Latins, was certainly sometimes applied to designate our gypsum, as may be seen in Theophrastus and in Pliny.

Gypsum occurs crystallized and amorphous. The purest sort is crystallized, and yields on analysis, sulphuric acid 46, lime 33, water 21 per cent. The primitive form of its crystals is a right oblique prism, which is variously modified. Its specific gravity is from 2·20 to 2·40. It is so soft as to be easily scratched by the nail.

Gypsum occurs in all the geological formations, especially in the secondary, and is found crystallized, granular, fibrous, compact, and earthy. When crystallized, it is distinctly foliated; and when the folia are large, it is termed selenite, from its reflecting a moon-like lustre.

Crystallized gypsum chiefly occurs at Bex in Switzerland; at Salzburg in the Tyrol; in New Castille, especially between Tembleque and Aranjuez; in Bohemia, France, New York, Nova Scotia; at Shotover in Oxfordshire, and at Chatley in Essex.

Granular and compact gypsum are the kinds used in sculpture, and occur snow-white near Volterra in Tuscany, in Spain, the Hartz, and other parts of Germany; in France, and in the salt formation of Cheshire. Fibrous gypsum is found at Ilfeld in the Hartz, in New Castille, Aragon; and in England in Cheshire and Derbyshire. Earthy gypsum occurs abundantly in New Castille and Aragon in Spain, at Salzburg, in Norway, and in various parts of North America. It is found in great quantity in the environs of Paris, along with a compact gypsum, in both of which the bones of the palæotherium, anoplotherium, and other extinct mammals were discovered by Cuvier. The gypsum beds of Paris contain 17 per cent. of carbonate of lime; and this sort has been named *Montmartrite*, from the locality where it occurs. This sort of gypsum forms the best *plaster of Paris*, as it resists the weather better than the purer gypsums.

There is another species of gypsum which contains no water of crystallization, and is therefore termed anhydrite. This mineral has a higher specific gravity than the common gypsum, and occasionally exhibits a fine pale blue colour. It occurs chiefly at Bex, at Sulz on the River Neckar, in Styria; at Bleyberg in Carinthia; in Upper Austria, and in Galicia.

Gypsum occurs in beds in gneiss and in mica-slate, and also in greywacke-slate; but its chief deposits are in the red clays of the secondary formation. It is found also in the tertiary formations; and even appears to be now forming, by the decomposition of iron-pyrites in contact with calcareous strata. It therefore must be considered as a member of all the great geological series of rocks.

Gypsum is important in an economical point of view. It is employed both in America and in Europe, as a top-dressing for meadow-lands with much advantage; but its principal use is for the formation of *plaster of Paris.* For this purpose it is burnt to expel its water of composition; and then when its powder is mixed with water, it forms a semi-liquid paste, that rapidly *sets* or dries by the absorption of the water; during which process a considerable heat is extricated, as was long ago remarked by Pliny. This extrication of heat is owing to the water giving out its latent heat on its condensation in the gypsum.

This property of rapid consolidation renders gypsum very available for taking casts of works of art, or objects of nature, as of sculptures, plants, and animals. It is much employed in architectural ornaments; and in Spain and France in the construction of vaults and floors. In smaller quantity it is employed in the glazing of porcelain; but its chief uses are for making casts, as a mortar, and in agriculture.

GYROMANCY, a kind of divination performed by walking or turning round in a ring or circle.

GYULA, a market-town of Hungary, county of Bekes, on the White Körös, which is here navigable, and divides the town into two portions—*Magyar* and *Nemelt*—in one of which only Hungarian, and in the other only German, is spoken. It has several oil mills, a castle, and an active trade in cattle and wine, which is extensively grown in the the districts. Pop. 15,000.

H.

H, the eighth letter of the English alphabet. It is properly a guttural aspirate semi-vowel, and indicates a breathing or forcible emission of the breath. Ben Johnson styles it "rarely other than an aspiration in power, though a letter in forme." By Bishop Wilkins, again, it is regarded as a *guttural vowel*, or sound formed in the throat by a full emission of the breath. Our H in *form* is the same as the uncial Greek *eta* (H); but it properly represents the ח of the Chaldee, Syriac, and Hebrew alphabets, which is also the eighth letter in each. H is sometimes mute in English, as in hour, honour, honest, hospital, &c.; or when united with *g*, as in right, fought, &c. H, as an old Latin numeral letter, denotes 200; and with a dash above it, ($\overline{H}$) 200,000. In Latin, as an abbreviation, H stands for *homo, hæres, hora, &c.;* thus, H. B. = *hæres bonorum;* HA. = Hadrianus; HH = *hæredes;* H. AQ. = *hic acquiescit.*

HAARLEM, Haerlem, or Harlem, a city of Holland, province of North Holland, on the Spaaren, 11 miles W. of Amsterdam, with which, as well as with Leyden, it communicates by railway. Haarlem was formerly a place of some strength. In 1572 it held out against a Spanish force, under the son of the Duke of Alva, for seven months, when terms of capitulation were offered to the besieged, and accepted. The Spaniards, however, had no sooner obtained possession of the town than they practised every species of cruelty upon the inhabitants, 2000 of whom were either put to the sword or tied in pairs and thrown into the lake. It was retaken by the Dutch in 1577. Part of the old fortifications still exist, including a venerable gateway on the high-road to Amsterdam. The town itself is well built and clean, but dull; and is traversed by numerous canals, which also connect it with all the principal towns of Holland. It has a fine market-place, round which are some of the finest buildings in the city. There are in all 15 churches belonging to various sects, including the cathedral of St Bavon, which is the largest church in Holland, and is celebrated for its organ, one of the largest and finest in the world. This instrument was built by C. Müller of Amsterdam in 1738, and has 8000 pipes and 60 stops. The Stadhuis and the Prinzenhof are among the finest edifices in the town. The latter has been converted into a museum of arts, antiquities, &c. In the market-place is a statue to Laurenz Janszoon Koster, whom the Dutch maintain to have been the inventor of printing. Haarlem is the headquarters of the Dutch establishment of national education, and the seat of the principal training seminary for schoolmasters in that kingdom. It has numerous literary and scientific institutions, including a botanic garden and public library. There are also extensive cotton factories and bleaching works, as well as manufactures of linen, silk, velvet, ribands, thread, &c. Excellent walks occupy the site of the ancient ramparts, and the neighbourhood is adorned with gardens and villas. In the S. outskirts of the town are famous nursery-gardens (*Bloemen Tuin*), where hyacinths, tulips, and other flowers, which constitute an important branch of trade in Haarlem, are reared. Pop. (1850) 25,778.

Haarlem Meer, or *Lake of Haarlem*, which has recently been drained, lay S.E. of the town, and was 14 miles long by 10 miles broad. It had been formed by an inundation in the end of the sixteenth century, which transformed four small lakes into one sheet of water, laid waste several villages, and destroyed much property. It continued gradually to gain upon the land, and in the beginning of the eighteenth century it covered an area of 45,000 acres. The people of Holland saw with much alarm the rapid extension of its boundaries, and at an expense of about L.33,000 succeeded in partially arresting its progress; but the annual cost of repairs to the works of defence had for a considerable period amounted to between L.3000 and L.4000. Various schemes had been proposed for the drainage of the lake, but it was not till 1839 that effectual means were taken for that object. On the 9th of November 1836 a furious hurricane from the west had driven the waters of the lake upon the city of Amsterdam, and inundated upwards of 10,000 acres of low land in the neighbourhood; and on the 25th of December following another hurricane impelled the water in the opposite direction upon the city of Leyden, the lower parts of which were submerged during 48 hours, and 19,000 acres of land covered with water. The enormous loss occasioned by these two storms determined the government on the drainage of the lake. The first business was to dig a canal round the lake for the reception of the water, and to accommodate the great traffic which had hitherto been carried on by means of it. This canal was made 38 miles in length, 130 feet wide on the west side, and 115 feet on the east side of the lake, and 9 feet deep. All the inlets into the lake were then closed by large earthen dams; and various works were executed to facilitate the flow of water into the sea. These preliminary works occupied till 1845. To give some idea of the magnitude of the undertaking, it may be mentioned that the area of water inclosed by the canal was rather more than 70 square miles, and the average depth of the lake was 13 feet 1·44 inches. The water had no natural outfall, being below the lowest possible point of sluiceage; and, including rain water, springs, &c., during the time of drainage, it was calculated that probably 1000 million tons would have to be raised by mechanical means. After drainage too, the site could only be kept dry by mechanical power, so that the annual drainage might amount to 54,000,000 tons, to be raised on an average 16 feet, and it might happen that as much as 35,000,000 tons of that amount would have to be raised in one month. A gigantic steam-engine of a peculiar construction, designed by Messrs J. Gibb and A. Dean of London, was erected and found to answer the highest expectations. It could raise 112 tons of water at each stroke, and was capable of discharging 1,000,000 tons in 25½ hours; while the consumption of fuel was only one-sixth part of the average consumption of ordinary draining engines. To describe this engine briefly;—it consists of two steam cylinders, one of 84 inches diameter placed within another of 144 inches diameter, both fitted with pistons, the outer being of course annular. The two pistons are united to a great cross head or cap, which is furnished with a guide rod or spindle—both pistons and cross-head being fitted with iron plates, and, together with parts of the engine attached, having an effective weight of nearly 90 tons. The engine-house is a circular tower, on the walls of which are arranged eleven large cast-iron balance-beams, which radiate from the centre of the engine. Their inner ends, furnished with rollers, are brought under the circular body of the great cap, and their outer ends are connected to the pistons of eleven pumps, each of 63 inches diameter; the stroke of both ends is 10 feet, and the discharge from the pumps is 66 tons of water per stroke. The action of the engine is very simple; it is on the high-pressure-expansive-condensing principle. The steam is admitted first beneath the small piston; and the dead weight of 90 tons is lifted, carrying with it the inner end of the pump balances, and of course allowing the pistons to descend in the pumps. The equilibrium valve then opens, and the steam in the cylinders passes round to the upper surface of the small and annular pistons, puts the former in a state of equilibrium, and presses with two-thirds of its force upon the annular piston, beneath which a vacuum is always maintained; thus the down stroke of the engine, and the elevation of the pump pistons and water, is produced by the joint action of the descending dead-weight in the cap and pistons, and the pressure of steam on the annular piston. The steam is expanded from six to eight times its original volume. The engine has two air-pumps of 40 inches diameter, and 5 feet stroke each. The total weight of iron employed for the engine-pumps, &c., is 640 tons; and the cost of the machinery and buildings was L.36,000. The water is lifted by the pumps into the canal, from which it passes off towards the sea-sluices. Two other engines of equal size and power were afterwards constructed by Messrs Harvey of Hayle and Messrs Fox and Co. of Perran, in Cornwall, the makers of the previous one. The pumping commenced in May 1848, and the lake was rendered dry by 1st July 1852. The first sale of the highest lands along the banks took place on 16th August 1853, when 784 hectares brought in 575,000 florins, or 733 florins per hectare. A second sale took place the same month, when 1273 hectares were sold for 742,450 florins, or 583 florins per hectare. Six sales have subsequently taken place, so that now 12,634 hectares (31,218 acres) have been sold for 5,973,953 florins (L.497,829). There are still (1856) 4200 hectares for sale, and 32 hectares reserved for villages; so that altogether 16,866 hectares, or 41,675 acres, have been reclaimed. The 12,643 hectares sold since 1853 have all this year produced their first or second crops.

The entire expense of drainage from 1839 to 31st December 1855 was 8,981,344 florins (L.748,445), which it is calculated will be entirely covered by the price of the reclaimed land.

HABAKKUK (*embraced* or *embracing*), one of the twelve minor prophets of the Old Testament. Of his history we have only apocryphal accounts; but from the designation (iii. 19) we may conclude that he was of the tribe of Levi, and officially connected with the musical service of the temple. The burden of his prophecy is in regard to the invasion of Palestine by the Chaldæans, which, though incredible when he wrote, was to happen in less than a generation after his time. Accordingly, his period may be fixed as between 650 and 627 B.C., not very long before the advent of Jeremiah, and at a still shorter interval before Zephaniah. His style is artistic, but, at the same time, pure. The canonicity of the book is undoubted. (Delitzsch, *Der Prophet Habakuk*, Leipzig, 1843.)

HABEAS CORPUS, in *English Law*, a celebrated writ, deriving its name, like other writs, from the formal words contained in it. This writ is used for various purposes; but the chief of these, being that which is always understood by *Habeas Corpus* without further explanation, is the release or bailing of a person who considers himself illegally imprisoned, or entitled to be discharged upon bail. Of the various other kinds made use of by the courts at Westminster, for removing prisoners from one court into another for the more easy administration of justice,—1st, The *habeas corpus ad respondendum* is issued when a man has a cause of action against one who is confined by the process of some inferior court, in order to remove the prisoner, and charge him with this new action in the court above; 2d, The *habeas corpus ad satisfaciendum* issues when a prisoner has had judgment against him in an action, and the plaintiff is desirous to bring him up to some superior court to charge him with the process of execution; 3d, The similar writs *ad prosequendum*, *testificandum*, *deliberandum*, &c., issue when it is necessary to remove a prisoner, in order to prosecute or bear testimony in any court, or to be tried in the proper jurisdiction in which the fact was committed; 4th, The common writ *ad faciendum et recipiendum*, issues out of any of the courts of Westminster Hall, when a person is sued in some inferior jurisdiction, and is desirous to remove the action into the superior court; commanding the inferior judges to produce the body of the defendant, together with the day and cause of his caption and detainer (whence the writ is frequently denominated a *habeas corpus cum causa*), to *do and receive* whatsoever the court shall consider in that behalf. But the great and efficacious writ, in all manner of illegal confinement, is that of *habeas corpus ad subjiciendum*, directed to the person detaining another, and commanding him to produce the body of the prisoner, with a specification of the day and cause of his caption and detention, *ad faciendum, subjiciendum, et recipiendum*, to do, submit to, and receive whatsoever the judge or court awarding such writ shall consider in that behalf. This is a high prerogative writ, and, therefore, by the common law, issues out of the Court of Queen's Bench, not only in term-time, but also during the vacation, by a fiat from the Chief-justice, or any other of the judges, and runs into all parts of the Queen's dominions except Scotland; for the sovereign is at all times entitled to have an account why the liberty of any subject is restrained, wherever that restraint may be inflicted. If it issues in vacation, it is usually returnable before the judge himself who awarded it, and he proceeds by himself thereon; unless the term should intervene, and then it may be returned in court. Indeed, if the party were privileged in the Courts of Common Pleas and Exchequer, as being an officer or suitor of the court, a *habeas corpus ad subjiciendum* might also have been awarded from thence; and if the cause of imprisonment were palpably illegal, they might have discharged him. But if he were committed for any criminal matter, they could only have remanded him, or taken bail for his appearance in the Court of King's Bench, which occasioned the Common Pleas to discountenance such applications. But since the mention of the King's Bench and Common Pleas as co-ordinate in this jurisdiction, by statute 16th Car. I., cap. 10, it has been held that every subject of the kingdom is equally entitled to the benefit of the common-law writ in either of those courts at his option. It has also been said, and by very respectable authorities, that the like *habeas corpus* may issue out of the Court of Chancery in vacation; but upon the famous application to Lord Nottingham by Jenks, notwithstanding the most diligent searches, no precedent could be found where the chancellor had issued such a writ in vacation, and therefore his lordship refused it.

In the Court of Queen's Bench it was, and still is, necessary to apply for it by motion to the court, as in the case of all other prerogative writs, such as *certiorari*, prohibition, *mandamus*, and the like, which do not issue as of mere course, without showing some probable cause why the extraordinary power of the crown is called in to the party's assistance. For, as it was argued by Lord Chief-Justice Vaughan, "it is granted on motion, because it cannot be had of course, and there is therefore no *necessity* to grant it; for the court ought to be satisfied that the party has a probable cause to be delivered." And this seems the more reasonable, because, when once granted, the person to whom it is directed can return no satisfactory excuse for not bringing up the body of the prisoner. So that, if it issued of mere course, without showing to the court or judge some reasonable ground for awarding it, a traitor or felon under sentence of death, a soldier or mariner in the service of the crown, a wife, a child, a relation, or a domestic, confined for insanity or other prudential reasons, might obtain a temporary enlargement by suing out a *habeas corpus*, though sure to be remanded as soon as brought up to the court. And therefore Sir Edward Coke, when Chief-justice, did not scruple (in 13 Jac. I.) to deny a *habeas corpus* to one confined by the Court of Admiralty for piracy, there appearing, upon his own showing, sufficient grounds to confine him. On the other hand, if a probable ground be shown that the party is imprisoned without just cause, and therefore has a right to be delivered, the right of *habeas corpus* is then a writ of right which "may not be denied, but ought to be granted to every man that is committed, or detained in prison, or otherwise restrained, though it be by the command of the king, the privy council, or any other."

Habeas Corpus Act is the famous act of 31st Car. II., cap. 2, which is frequently considered as another *magna charta* of the kingdom. It enacts—1. That on complaint and request in writing by or on behalf of any person committed and charged with any crime (unless committed for treason or felony expressed in the warrant), or as accessary, or on suspicion of being accessary, before the fact, to any petit-treason or felony, plainly expressed in the warrant, or unless he is convicted or charged in execution by legal process, the Lord Chancellor, or any of the twelve judges in vacation, upon viewing a copy of the warrant, or affidavit that a copy is denied, shall, unless the party has neglected for two terms to apply to any court for his enlargement, award a *habeas corpus* for such prisoner, returnable immediately before himself or any other of the judges; and, upon the return made, shall discharge the party, if bailable, upon giving security to appear and answer to the accusation in the proper court of judicature. 2. That such writs shall be indorsed, as granted in pursuance of this act, and signed by the person awarding them. 3. That the writ of *habeas corpus* shall be returned and the prisoner brought up, within a limited time according to the distance, not exceeding in any case twenty days. 4. That officers and keepers neglecting to make due returns, or not delivering to the prisoner or his agent, within six hours after demand, a copy of the warrant of commitment, or shifting the custody of a prisoner from one to another without sufficient reason or authority (specified in the act), shall, for the first offence, forfeit L.100, and for the second offence L.200, to the party grieved, and be disabled to hold his office. 5. That no person, once delivered by *habeas corpus*, shall be re-committed for the same offence, on penalty of L.500. 6. That every person committed for treason or felony shall, if he requires it the first week of the next term, or the first day of the next session of *oyer* and *terminer*, be indicted in that term or session, or else admitted to bail, unless the crown witnesses cannot be produced at that time; and if acquitted, or if not indicted and tried in the second term or session, he shall be discharged from his imprisonment for such imputed offence; but that no person, after the assizes shall be opened for the county in which he is detained, shall be removed by *habeas corpus* until after the assizes are ended, but shall be left to the justice of the judges of assize. 7. That any such prisoner may move for and obtain his *habeas corpus* as well out of the Chancery or Exchequer as out of the King's Bench or Common Pleas; and the Lord Chancellor or judges denying the same, on sight of the warrant, shall, on oath that the same is refused, forfeit severally to the party grieved the sum of L.500. 8. That the writ of *habeas corpus* shall run into the counties palatine, cinque ports, and other privileged places, and the islands of Jersey and Guernsey. 9. That no inhabitant of England, except persons contracting, or convicts praying to be transported, or having committed some capital offence in the place to which they are sent, shall be sent prisoners to Scotland, Ireland, Jersey, Guernsey, or any places beyond the seas, within or without the British dominions, on pain that the party committing, his advisers, aiders, and assistants, shall forfeit to the party grieved a sum not less than L.500, to be recovered with treble costs, shall be disabled from holding any office of trust or profit, shall incur the penalties of *præmunire*, and shall be incapable of the royal pardon.

This is the substance of that great and important statute, which extends only to the case of commitments for such criminal charges as can produce no inconvenience to public justice by a temporary enlargement of the prisoner; all other cases of unjust imprisonment being left to the *habeas corpus* at common law. But even upon writs at the common law it is expected by the court, agreeably to ancient precedents and the spirit of the act of parliament, that the writ should be immediately obeyed, without waiting for any *alias* or *pluries;* otherwise an attachment will issue. By these admirable regulations, judicial as well as parliamentary, the remedy is now complete for removing the injury of unjust and illegal confinement; a remedy the more necessary, because the oppression does not always arise designedly, but sometimes from the mere inattention of government. For it frequently happens in foreign countries, and has happened in England during the temporary suspension of the statute, that persons apprehended upon suspicion have suffered a long imprisonment merely because they were forgotten.

In *Scots Law*, the form corresponding to the *habeas corpus* is called "Running Letters."

HABERDASHER, a dealer in such wares as silks, ribbons, cotton and woollen fabrics, &c. The word has ingeniously been derived from the Saxon *hab vihr das, i.e.,* Will you buy this? but its etymology is very doubtful.

HABERGEON, a coat of mail, or piece of defensive armour, descending from the neck to the middle, and formed of little iron rings linked into each other. It is also written *haberge, hauberge, haubere, haubert, hautber, hautbert,* and *hauberk.* Spelman derives it from the ancient French *hault,* high, and *berg,* armour or covering; Du Cange and Skinner from the Belgic *hals,* or Teutonic *haltz,* neck, and *bergen,* to defend.

HACHETTE, Jean Nicolas Pierre, an eminent French geometer, was born at Mézières, May 6, 1769 or 1770. His father was a barber, and without the means of educating his son. The genius of the youth, however, was speedily recognised by Monge, then living at Mézières. By his kindness the young Hachette was sent to the university of Reims, where he studied so successfully, that at the age of twenty-three he defeated all his fellow candidates in the *concours* for the professorship of hydrography at Collioure and Port-Vendre. When the polytechnic school was opened in 1794, Hachette was attached to the professional staff, with the department of descriptive geometry, and trained some of the very best geometers of his age and country, such as Poisson, Arago, Fresnel, and many others. He held this office till the restoration of the Bourbons, who deprived him of it and expelled him from the Institute. The Revolution of 1830 reinstated him in his offices and honours, of which he retained peaceful possession till his death, four years later, Jan. 16, 1834. Hachette's character as a man stood as high as his scientific fame. His personal worth was of that solid and unostentatious kind, more common in England than in France, though appreciated quite as fully in the latter as in the former country. His high sense of duty, his simplicity, and his quiet benevolence, endeared him to all who enjoyed the privilege either of his instructions or of his private friendship. His services to science lay chiefly in the field of descriptive geometry, with which he was profoundly acquainted, both in its theory and its practical application to the arts, especially in the construction of machinery. To him is due the merit of having given to machinery that impulse, in virtue of which France has in that department advanced so rapidly and so far since his day.

Hachette's principal works are his *Deux Suppléments à la Géométrie Descriptive de Monge*, 1811 and 1818 respectively; *Elémens de Géométrie à Trois Dimensions*, Paris, 1817; *Collection des Epures de Géométrie à Trois Dimensions*, &c., 1795 and 1817; *Applications de Géométrie Descriptive*, Paris, 1817; *Traité de Géométrie Descriptive*, &c., Paris, 1822; *Traité Elémentaire des Machines*, Paris, 1811; *Correspondance sur l'Ecole Polytechnique*, 1804–1815. Hachette also contributed many valuable papers to the leading scientific journals of the day.

HACKET, John, D.D. (1592–1670), bishop of Lichfield and Coventry, was educated first at Westminster and afterwards at Trinity College, Cambridge. In the civil war he espoused the royal cause with an indiscreet zeal that got him into trouble when victory sided with the parliament. At the Restoration, however, he was promoted to the bishopric of Lichfield and Coventry, which he held till his death. Hacket's name will be long remembered in the history of church architecture in Britain. He restored, with skill and success, the cathedral of Lichfield, which had been seriously damaged in the iconoclastic fury of the Puritans. With indefatigable zeal he set himself to collect subscriptions for its repair, which seems to have cost about L.20,000. Of this sum he contributed himself nearly one-tenth. As an author, Hacket is only known to have written *Loyola*, a comedy which was twice acted before James II. After his death appeared a *Century of Sermons on several remarkable subjects,* and a *Life of Archbishop Williams.* All these works are now forgotten.

HACKNEY, a suburb of London, parish of St John, Hackney. See LONDON.

HACKNEY *Coaches.* See COACH. The term is derived from the French *haquenée*, a strong kind of horse formerly lent out on hire for short journeys in France, and afterwards employed to draw a plain vehicle for the accommodation of several travellers together. This vehicle was called *coche-à-haquenée*, whence the term hackney-coach.

HACQUETON, a stuffed jerkin, generally of leather, formerly worn under armour.

HADDINGTON, a royal burgh of Scotland, and county town of Haddingtonshire, or East Lothian. It stands on the left bank of the Tyne, about 17 miles from Edinburgh, on the post road between that capital and Berwick-upon-Tweed. Haddington is a town of great antiquity, but the exact date of its origin is unknown. It is first mentioned in the records of the 12th century as part of the demesne of the Scottish king. It was created a burgh by David I., who held it, along with a church and mill, and other appurtenances of a manor. Ada, wife of Henry the son and heir of this monarch, received this burgh as her dower, and was very attentive to its interests. In 1178 she founded here a convent of Cistercian nuns, and endowed it with the lands of Clerkington. After her death, the burgh became the property of her son, William the Lion, whose son, Alexander II., was born here in 1198. In 1216 Haddington was burnt, along with the neighbouring burgh of Dunbar, by an invading army under John, king of England. Being rebuilt with wood, it was again burnt to the ground in 1244. Some attributed the fire to the work of an incendiary, for it was remarked that six other Scottish towns were burnt on the same night. In 1355, it was reduced to ashes for the third time by Edward III. of England, and the monastery of Haddington, with the splendid church of the Franciscans or Grey Friars, destroyed. The choir of this church, from its great elegance, and from the number of lights kept constantly burning in it, was commonly called the Lamp of Lothian (*Lucerna Laudoniæ*). The year after the battle of Pinkie, 1548, Haddington was seized and strongly fortified by the English. An allied army of Scotch and French laid siege to it, and, after a memorable defence, it was evacuated by the English in October 1549. In 1598 this town was again consumed by fire; but in this instance the fire was entirely accidental.

Haddington, being built on low ground, little above the level of the Tyne, has repeatedly suffered from inundations of that river. In 1358, in 1421, and in 1673, the Tyne rose to a great height, and did much damage to the town and neighbourhood. But the greatest inundation took place on the 4th of October 1775, when the river rose 17 feet above its usual level, overwhelmed the suburb of Nungate on the east bank, and laid a great part of the town under water. Had the highest flood occurred during the night, the loss of life would have been very great. A tablet, recording the providential deliverance of the town, is still to be seen on one of the corners of the main street.

The ancient walls and fortifications of Haddington have now quite disappeared. Some of the old houses possessed by the nobility when Haddington was a royal residence, still exist, but in a very dilapidated state. The palace of the Scottish kings is said to have stood near the West Port, on the spot now occupied by the new county buildings, erected in 1833. The town consists of a Main or High Street, stretching from east to west, and forming a portion of the post road to Berwick. It is a spacious and handsome street, and possesses some elegant buildings. Parallel to it, on the north, runs the Back Street, having two cross streets at its eastern extremity. The town-house is a respectable and commodious fabric, with a fine spire 150 feet high, built in 1831. A few years ago, a large new prison for the town and county, on the most approved principles, was built on ground closely adjoining the county buildings; the old premises, which were connected with the town-house, having been found quite insufficient.

There are two bridges over the Tyne, one, of great antiquity, connecting the town with the suburb of the Nungate; and the other, called Waterloo Bridge, built in 1817, on the south of the town, giving access to the Bolton and Salton road. In the Nungate the ruins of an ancient chapel dedicated to St Martin still exist. The ancient and splendid monastery of the Franciscans was long the chief architectural glory of Haddington. It was 210 feet in length, and was surmounted by a noble square tower 90 feet high. The tower and principal parts of the building still stand, though partly in ruins. In 1811, the chancel or west end of the cross was repaired, and now forms the present parish church. For 200 years Haddington has been a collegiate charge, and has possessed the services of two ministers of the Established church. It has also two Free churches, two churches of the United Presbyterians, an Independent church, and an Episcopal chapel.

Haddington being in the centre of a highly cultivated district has long possessed an excellent weekly corn market, which is held on Friday. It is one of the ruling markets for grain in Scotland, and is resorted to by dealers from all parts of the country. A large and commodious corn exchange has been lately opened for the transaction of business. Several woollen manufactories have been tried in Haddington, but without success. There are several tanneries and breweries, and a few other branches of business, such as are usually found in a county town. The following banks have branches in Haddington:—Bank of Scotland, British Linen Company, Western Bank of Scotland, and City of Glasgow Bank.

Under the late Burgh Reform Acts, the government of Haddington is vested in a provost, three bailies, a dean of guild, a treasurer, and twelve councillors. The ordinary sheriff court during session meets every Monday and Thursday. The Small-Debt Court is also held on Thursday. Monthly Justice of Peace Courts are also held on the second Tuesday of each month. The Quarter Sessions are held on the first Tuesdays of March, May, August, and October.

The Burgh or Grammar Schools of Haddington, under the patronage of the magistrates, have usually enjoyed a high reputation. The celebrated Edward Irving was once one of its masters. There are four good libraries in the town, one of which was founded about the year 1717. Mr Samuel Brown, a native of the town, was the means of instituting in 1817 "The East Lothian Itinerating Libraries," which have done much good throughout the county. There is also a good reading-room, a savings bank, several branch banks, a town mission, and an infant-school. The United East Lothian Agricultural Society and the East Lothian Horticultural Society have their seats in Haddington. The population of the burgh and parish amounted in 1821 to 5255, in 1831 to 5883, in 1841 to 5452, and in 1851 to 5525. Haddington unites with Dunbar, North Berwick, Jedburgh, and Lauder, in sending a member to parliament. Its electors in 1855 amounted to 205.

Haddington claims the honour of being the birthplace of John Knox; but it will, perhaps, be always disputed whether that great reformer was born in the Giffordgate of Haddington, or in the village of Gifford, 4 miles to the S. of the town. It is certain, however, that he spent his early life in Haddington, and was educated at its Grammar School. The Rev. John Brown, author of the *Dictionary of the Bible,* and other popular religious works, was a dissenting minister in Haddington, and there spent the greater part of his useful and laborious life. It may also be mentioned that

Alexander II., king of Scotland, was born here in 1198. Andrew Maitaland, a native of Haddington, was married in 1657, and had nine children, whose united ages amount to 738 years.

Haddington gives the title of earl to the Hamiltons of Byres and Tyninghame.

The quantity and value of grain sold in the Haddington grain market, from September 22, 1854, to September 21, 1855, were as follows :—

	Qrs.	Value.			Highest Average.	
Wheat...........	26,923	L.97,127	9	5	85*s*.	10*d*.
Barley...........	24,419	42,357	1	2	39	1
Oats...............	20,548	32,237	6	5	35	6
Beans............	4,889	11,543	3	6	54	1

For the ancient and modern history of Haddington, see *The Lamp of Lothian*, by James Miller, author of *St Baldred of the Bass*, and the *History of Dunbar*.

HADDINGTONSHIRE, or East Lothian, a county in Scotland, lying between N. Lat. 55. 47. and 56. 5., and W. Long. 2. 25. and 3. 2. It is bounded on the N. and E. by the Firth of Forth and German Ocean, S. by Berwickshire, and W. by Edinburghshire, or Mid-Lothian. Its boundaries are somewhat irregular, but its extreme length from W. to E. may be about 25 miles, and its extreme breadth about 17. According to the ordnance survey of this county recently completed, its area is as follows :—Land, 173,298 acres; water, 190; links, 149; foreshore, 5505—total, 179,142 acres, or 280 square miles. Of the "land" portion fully four-fifths are considered to be arable, and even under cultivation. The remaining portion, which is only fit for pasture, is almost exclusively composed of the Lammermoor district, which bounds the county from Soutra on the S.W. to Cockburnspath on the N.E. With the exception of this hilly district on the S., the whole county is highly cultivated, as there is no considerable forest, marsh, or heath, to resist the plough. Few counties in Scotland present such a fair and unbroken picture of agricultural wealth and activity.

When viewed from the ridge of the Lammermoors, Haddingtonshire appears to slope gradually to the Firth of Forth and the German Ocean ; but, upon a nearer survey the declivity is found to consist of nearly parallel ridges, running from W. to E., and most of them extending nearly the whole length of the county. Towards the termination of these ridges on the E. there is an extensive and very fertile plain, stretching northwards along the sea-coast. In the low country, North Berwick Law, and Traprain Law, near the centre of the county, are very conspicuous objects, from their regular cone-like appearance. The Garlton Hills, a range of moderate height to the north of the town of Haddington, although not picturesque in themselves, command some of the finest views in the county.

The soil of Haddingtonshire is very varied, but clay and loam, nearly in equal proportions, though of various qualities, extend over about two-thirds of the county. A great deal of both descriptions is not naturally very fertile, much of the clay, in particular, being shallow, and lying on a wet bottom. Tracts of moorish soil are also found in some districts, as in the parish of Gladsmuir. Yet, on the whole, the soil of this county is highly favourable for agricultural purposes. What part of it is naturally not good is very susceptible of improvement, and has actually been greatly improved by judicious drainage, and a superior style of agriculture.

The climate of Haddingtonshire is undoubtedly one of the best in Scotland, especially for the production of grain crops. In point of dryness it is much above the average ; and from the absence of swamps or morasses, and the extensive agricultural drainage, it is remarkably free from fogs and noxious exhalations. In certain districts where ague was once very common, that disease is now unknown, and the salubrity of the air has greatly increased. The amount of rain that falls in the lower parts of the county, especially around Dunbar, is considerably less than in most other counties of Scotland ; and to this cause is ascribed the superior quality of the wheat and other kinds of grain. The harvest in the eastern districts, and along the coast northward, is in general early, and is often ended before the harvest in the higher tracts is well begun. Snow, which sometimes lies for months in the Lammermoors, seldom lies long in the lower grounds, and near the coast disappears for the most part as rapidly as it falls. In the winter and spring months the prevailing winds are from the N. and E. ; in summer, when the weather is dry, from the E. ; and in autumn from W. to S. and S.E. The N.W. wind brings storms in winter, and from that quarter, as well as from the S.W., come the high gales which are sometimes so injurious to the standing corn in autumn.

The streams in Haddingtonshire are inconsiderable in number and extent. The Tyne, which is the largest, rises in Mid-Lothian, and enters this county on the W. near Ormiston, passes Haddington, and falls into the sea at Tyninghame, between Dunbar and North Berwick. There are also the Whitadder, the Dye, the Fasney, the Moneynut, and Bothwell Water, all flowing in a south-easterly direction. The only lake of any importance in this county is Pressmenan, in the parish of Stenton, and that is an artificial one. It is about a mile and a half in length, and is very narrow ; but it is surrounded with beautiful woods, and affords excellent fishing.

Coal is found in great abundance and of fair quality in five of the western parishes of this county, namely, Prestonpans, Pencaitland, Ormiston, Tranent, and Gladsmuir. It appears from old charters that the monks of Newbattle wrought coal in the parish of Prestonpans so early as the first part of the thirteenth century. This is understood to be the first recorded instance of coal being wrought in Scotland. Limestone is also very abundant, and is more equally diffused over the county. Marl is found at Salton and other places, but its use is superseded by the application of lime. Sandstone, or freestone, well adapted for building purposes, is quarried in Garvald, Pencaitland, Tranent, and many other places. Ironstone has been found in the parishes of Humbie, Oldhamstocks, and Tranent ; but it is only of late that iron has been manufactured in this county with any success. A furnace for the smelting of iron ore has been recently erected at West Bank, parish of Gladsmuir, and the iron manufactured has proved to be of excellent quality.

In the Lammermoors, near the junction of the Fasney with the Whitadder, granitic rocks appear ; but the prevalent rocks over the county are those of a secondary character. Old red sandstone appears on the northern slope of the Lammermoors. Traprain Law, in the centre of the county, is composed, at its base, of a slaty clinkstone, and towards the summit, of a greenstone, slightly granulated with hornblende. North Berwick Law, a conical hill, rising immediately above the town of North Berwick to the height of 612 feet, is another of those bold eminences of the trap order, which break the monotony of the East Lothian landscape. The Bass Rock presents a singular specimen of a mass of trap rock rising up abrupt and perpendicular 350 feet from the surface of the sea. This trap rock, according to the continental geologist M. A. Boué, is a compact clinkstone, and according to Mr J. Nicol, "a fine granular greenstone or clinkstone." Hugh Miller pronounces it to be "of an intermediate hybrid species," partaking of the character both of clinkstone and greenstone. (See *The Bass Rock, its Civic and Ecclesiastical History, Geology*, &c. &c.)

According to the recent trigonometrical survey the heights of the principal eminences in this county are as follows :—Lammerlaw 1732 ft., Lammermin 1692, Spartleton 1500, Doon Hill 583, Traprain Law 586, Garlton Hill 573.

These measurements, some of them materially differing from those given by the ordinary authorities, must be held to be correct.

The British antiquities of Haddingtonshire are neither very numerous nor very important. In various parts of the Lammermoors, stone circles of Druidical origin are found. The remains of hill forts and circular camps are also found at Garvald, Carfrae, Priestlaw, Spott, and other places. Urns composed of clay, and supposed to be of a funereal character, are not unfrequently discovered on the higher grounds. Tall upright single stones are to be seen standing in various places. There is one, for example, in a field near Linton, and another at Broomhouse, near Spott. The battle-field of Dunbar, where Cromwell defeated the Covenanting army, under General Leslie, in 1650; and the battle-field of Prestonpans, where the royal forces were defeated by the Highland army in 1745, are the only spots of historical interest.

Haddingtonshire contains some fine ruins of ancient castles. The castle of Dunbar, perched upon two bold rocks that overhang the sea, is now a complete ruin, but it still forcibly speaks to the eye of the warlike character of former ages. Tantallon Castle, in the parish of North Berwick, is also close upon the sea, and with its immense piles of masonry still standing, undoubtedly forms one of the most magnificent ruins in Scotland. Dirleton Castle, near the beautiful village of that name; Hailes Castle, in the parish of Prestonkirk, on the south bank of the Tyne, famed in the history of Queen Mary; and Innerwick Castle, four miles east of Dunbar, are also interesting ruins.

There are many seats of the nobility and gentry in East Lothian. Of these, the principal are Yester House, the seat of the Marquis of Tweeddale; Gosford House and Amisfield, seats of the Earl of Wemyss; Tyninghame House, the seat of the Earl of Haddington; Ormiston Hall, a seat of the Earl of Hopetoun; Saltoun Hall, the residence of Andrew Fletcher, Esq., a descendant of the celebrated patriot; Archerfield and Beil, seats of Mr and Lady Mary Hamilton-Nisbet; and Whittingham House, the seat of James M. Balfour, Esq.

This county has long enjoyed the benefit of excellent roads and other means of transport; while its small but useful seaports have been of great service to its agriculture. The first Scottish turnpike act was obtained in 1750 for the formation of a road through the county. In an agricultural point of view East Lothian occupies an important position among the other counties of Scotland. There are very few small farms, and, except in the hill districts, the largest seldom exceed 500 imperial acres. On land of a medium quality, a farm of 300 acres is considered to be of an average size. Farms are commonly held on leases of 19 or of 21 years, and these leases are generally of a fair and equitable character. In some instances of late the tenant has the power to kill game on his farm, a privilege which is attended with the best consequences. In the article AGRICULTURE, Appendix A, vol. ii., p. 368, will be found a detailed account of the agricultural condition and prospects of this county.

At various periods attempts have been made to introduce different manufactures into Haddingtonshire, but with no permanent success. At the present time no manufactures of importance are carried on in the county; and various attempts made to introduce the manufacture of cotton, muslin, &c., have proved entirely abortive. The breweries of Prestonpans and Belhaven are still famous; but the once extensive potteries of the former place have now dwindled away. The principal towns are Haddington the county town, Dunbar, North Berwick, Tranent, and Prestonpans. These are described under their respective names.

Haddingtonshire has given birth to not a few eminent men, and is associated with the history of many more. It is well known that John Knox, the renowned Scottish Reformer, was a native of this county, being born, according to some authorities, at Haddington; or, according to others including his distinguished biographer, Dr M‘Crie, at Gifford, a village four miles to the south of Haddington. Dr Witherspoon and the Rev. Marcus Dods were natives of Gifford. Fletcher of Salton, and Lord Belhaven, who distinguished themselves at the period of the Union, are East Lothian celebrities. George Heriot, the founder of Heriot's Hospital in Edinburgh, was a native of the parish of Gladsmuir. Dunbar, the poet, is said to have been born at Salton in 1465; and Gilbert Burnet, afterwards Bishop of Salisbury, was minister of the same parish from 1665 to 1669. Principal Robertson was for several years minister of Gladsmuir, where he wrote his *History of Scotland*. Blair, the author of *The Grave*, and John Home, the author of *Douglas*, were successively ministers of Athelstaneford. Skirving, the painter, was also a native of Athelstaneford. The pious Colonel Gardiner, who fell in the Battle of Prestonpans, 1745, near his own mansion, Bankton House, was buried in Tranent Churchyard. A handsome obelisk has lately been erected to his memory, near the spot where he fell, which is within a few yards of the North British Railway.

The county is divided into twenty-five parishes, which are all ecclesiastically embraced in the presbyteries of Haddington and Dunbar, except Ormiston and Fala, which belong to that of Dalkeith. The poor are supported by assessment under the recent act, and the rate seldom exceeds in any parish a shilling in the pound. In 1853 the expenditure on the poor in the twenty assessed parishes amounted to L.8127; the total expenditure in the whole county was L.9360. In 1854 the total expenditure was L.9999.

The charitable educational foundations in this county are the following:—Schaw's Hospital, in the parish of Prestonpans, founded by James Schaw of Preston, for the education and maintenance of poor boys, and opened in 1789, now admitting 24 boys; Stiell's Hospital, in the parish of Tranent, founded by George Stiell, builder in Edinburgh, which maintains a few boys and girls as boarders, and gives free education to 140 day scholars, the revenue amounting at present to L.900 a year; an endowment of 20,000 merks bequeathed by Bishop Burnet to his old parish of Salton, towards the enlargement and support of a library for the use of the minister, also for clothing and educating thirty poor children, and otherwise relieving the necessities of the parochial poor.

The following tables—compiled from the returns lately procured through the agency of the Highland and Agricultural Society of Scotland—will show the present state of the agriculture of Haddingtonshire:—

Acres in Tillage.

Year.	Average.*	Wheat.	Barley.	Oats.	Beans and Peas.	Potatoes.	Turnips.
1853	107,269	15,339	12,809	16,802	4,809	4,246	
1854	98,977	16,881	12,086	15,668	3,956	6,442	15,342
1855	101,528	17,472	10,856	16,692	4,100	6,451	16,063

* This average merely represents the gross number of acres in tillage, or arable, returned by the enumeration.

Stock of various kinds.

Year.	Horses.	Milk Cows.	Other Cattle.	Ewes, Gimmers, and Hogs.	Tups, Wethers, and Wether Hogs.	Swine.
1853	4450	2377	7576	36,979	29,597	5580
1854	4171	2130	5390	42,551	33,881	5702
1855	4481	2069	5508	† 86,853		4676

† Returns differently made in 1855.

HADDOCK. See index to ICHTHYOLOGY.

HADELN, a district of the kingdom of Hanover, comprising about 110 square miles of rich marsh land, near the mouth of the Elbe. It contains two market-towns and twelve parishes, with about 20,000 inhabitants. It is chiefly remarkable for the privileges it enjoys of a very slight fixed taxation, and a freedom from the quartering of troops, which have been granted on account of the great expenditure incurred by erecting and keeping up dikes, to prevent the irruption of the sea. It produces abundant crops of corn, beans, rapeseed, flax, and garden fruits, and fattens many oxen. The chief town is Altenbruck, which contains 2500 inhabitants.

HADERSLEBEN, Danish *Haderslev*, a seaport-town of Denmark, duchy of Schleswig, and 48 miles north of the town of that name. It stands in a pleasant valley on the Hadersleben Fiord, which is about 9 miles in length, and communicates with the Little Belt. It has three churches, a gymnasium, and some trade, but the harbour is accessible only to small vessels. Pop. 6156.

HADES, in *Grecian Mythology*, the lower world or kingdom of the dead. Etymologically, the word signifies the unseen or invisible world. The older Greek authors originally used the word to signify the king of this region, whom they afterwards called by the more euphemistic name of Pluto. This latter name was adopted by the Romans, and identified by them with Dis, Orcus, &c. Hades as Pluto was the son of Saturn, and the brother of Jupiter and Neptune. When the three brothers were parcelling out the world into three kingdoms, that of the invisible world fell to the lot of Pluto, who is always described as the most terrible of the gods. He was as inexorable as the Fates, and as cruel; and no shade that entered his portals ever escaped from them. In accordance with these gloomy attributes, the victims offered in his honour were always black, and the worshipper in sacrificing them always turned away his head. There are few legends in the old mythology whose interest centres in this deity, if we except those of the rape of Proserpine, and the helmet which made the god invisible, and from which perhaps he got his name.

HADHRAMAUT, a province of Arabia. See vol. iii., p. 356.

HADLEIGH, a market-town of England, county of Suffolk, on the Bret, a tributary of the Stour, 9 miles W.S.W. of Ipswich. It was formerly a corporate town, and a place of considerable trade, but it has lost its charter; and its trade, which was chiefly in cloth, has declined. Silk-spinning is carried on to some extent, but the inhabitants are chiefly employed in agriculture. The church is a large and handsome building, with a tower and spire. Dr Rowland Taylor, rector of Hadleigh, was burned here in the reign of Queen Mary, the spot being marked by a stone with this inscription,—"1555. Dr Taylor, in defending that was good, at this plas left his blode." Market-day, Monday. Pop. (1851) 3338.

HADLEY, JOHN (—— 1744), a distinguished English astronomer, of the details of whose life almost nothing is known. He was a member and afterwards a vice-president of the Royal Society, to whose *Transactions* he made some valuable contributions. He was the inventor of the sextant which bears his name, or at least the first who made it practically useful at sea; for the idea had been long before struck out by Hooke and perfected by Newton. Some important changes and improvements have since been made upon it by Mayer and Borda.

HADRIANOPOLIS, in *Ancient Geography*, the name of several cities founded by the Emperor Hadrian, by whose name they were called. The largest and most important of these was that in Thrace, at the confluence of the Hebrus and Tonzus, which seems to have occupied the site of the more ancient city of Uscudama. It stood in the midst of a country of remarkable fertility, and its commerce and manufactures soon raised it to great importance. Its arms were noted over the East. It was besieged by the Goths in 378, but it soon recovered the shock, and was for many centuries the largest city in the Eastern Empire after the capital. (For its modern history, see ADRIANOPLE.) There were three other minor towns of this name, one in Bithynia, another in Phrygia, and a third in Illyricum, half-way between Nicopolis and Apollonia. The name of the last was changed into Justinopolis by the Emperor Justinian, who fortified and repaired it.

HADRIANUS, P. Olius, was born at Rome, A.D. 76; died at Baiæ, A.D. 138. He succeeded Trajan as Emperor of Rome in A.D. 117, and reigned for twenty-one years. See Roman History.

HADRUMETUM, or Adrumetum, and Adrumetus, in *Ancient Geography*, a city and seaport on the coast of Africa Propria. It was a Phenician colony of more ancient date than Carthage itself, to which it afterwards became subject. The adjoining country was of amazing fertility, and was sheltered from the sands of the desert by an amphitheatre of hills. The town itself was strongly fortified. Hannibal, when recalled from Italy, passed through it on his way to the scene of his last battle at Zama. Like most cities of Northern Africa, Hadrumetum suffered severely at the hands of the Vandals, but it was afterwards restored by Justinian, in whose honour it was called Justiniana or Justinianopolis. Considerable doubts have been entertained as to its site, but modern geographers have identified it with Susa, where extensive and splendid ruins were seen and described by the Arab geographer, Abu Behri of Cordova. Traces of these ruins were observed by the African traveller Barth, who describes them in his *Wanderings among the Coastlands of Carthage and Cyrene.* See also *Shaw's Travels in Barbary.*

HÆMOPTYSIS (αἷμα, blood, πτύειν, to spit), the coughing up of blood from the lungs. Its florid colour, frothiness, and comparatively small quantity, serve to distinguish it from blood coming from the stomach, which is generally darkened by admixture with the gastric juice, &c.

HÆMORRHAGE, or Hæmorrhagy (from αἷμα, blood, and ῥήγνυμι, to burst), a flux of blood arising from the rupture of a bloodvessel. The Greeks restricted the use of this term to a discharge of blood from the nose; but in modern use it is extended to a flux of blood from the nose, lungs, intestines, &c. The word is often spelled *hemorrhage.*

HÆMUS, the ancient name of the Thracian mountain range now known as the Emineh Dagh, or Balkan. See Balkan.

HÆRETICO Comburendo, a writ which anciently lay against an heretic, who, having once been convicted of heresy by his bishop, and having abjured it, but afterwards falling into it again, or into some other, is thereupon committed to the secular power. See Heresy.

HAERLEBEKE, or Harlebeke, a town of Belgium, province of West Flanders, and arrondissement of Courtrai, on the Lys, and on the railway between Courtrai and Ghent, 3 miles N.E. of the former town. It has some woollen manufactures. Pop. (1851) 4677.

HAFF, or Stettin Haff, a lagoon in the Prussian province of Pomerania, lying N. of Stettin, and communicating with the Baltic by several mouths. It is about 30 miles in length from E. to W., by about 12 miles in breadth; and is divided into the Great and Little Haff. It receives the Oder, Ihna, Ucher, and Peene rivers.

HAFIZ, Shems Eddin Mohammed, one of the most elegant and popular poets of Persia, was born at Shiraz about the beginning of the fourteenth century. Neither the date of his birth nor that of his death is accurately known. He was carefully trained in law and the doctrines of the Koran, but he seems to have devoted the better part of his life to the service of the muses. A pleasant tradition describes how he first donned their livery. There is a place called Pirisebz, at a little distance from Shiraz; and it was a popular belief that a youth who should pass forty consecutive nights there without sleep would become an eminent poet. Hafiz made the experiment, and on the morning after the fortieth night an old man in a green mantle (who was no other than Khizr in person) came forward, and, presenting him with a brimming cup of nectar, rewarded his perseverance with an inspiring draught. From this time he devoted himself to poetry, and with such success, that the Sultan of Bagdad hearing of his fame, invited him to his court. The poet, however, does not seem to have accepted the invitation, or, if he did, it was only for a short time. When Shiraz fell into the hands of Tamerlane, the poet was summoned into the presence of the conqueror. In one of his lyrics the poet had said—

> "O pride of Shiraz, nymph divine,
> Accept my heart, and yield me thine;
> Then were its price all Samarcand,
> The wealth Bokhara's walls command,
> That pretty mole of dusky dye
> Thy cheek displays, I'd gladly buy."

Tamerlane, believing that the poet meant to cast a slight on the chief cities of his empire, reproached him with his promise to exchange Samarcand and Bokhara for the favours of his mistress. "It is that very generosity," said the poet, "that has made me so poor as you now see me." The date of Hafiz's death is variously given. Daulet-Shah places it in 1389. The poet was suspected of having been an unbeliever, and even at heart a Christian; and it was only with considerable difficulty that his friends obtained a decent burial for his body. A splendid monument over his grave is inscribed with a half-enigmatical legend which seems to confirm the testimony of Daulet-Shah as to the date of his death.

Hafiz is the Anacreon of Persia. His poetry, which is wholly lyrical, is devoted to the praises of wine and flowers, and nightingales and female beauties, for all of which Shiraz was famous. From these themes, however, he passes with startling rapidity to the gravest moralizing on the chances and changes of life, and the instability of all human things. The more strict of his co-religionists regard his works as, on the whole, dangerous in their tendency; while those who defend the poet maintain that they are not to be interpreted in a literal, but in an allegorical sense. The probability is that both are right; and that the poet—by turns a devotee and a debauchee—gave to the ode the cast of thought that happened to prevail at the moment when it was written. Sir William Jones, who strongly advocates the allegorical method, confesses that many of the odes can only be interpreted in a literal sense. The sect of the Sufis, with whom Hafiz had identified himself towards the close of his life, refuse to make even this concession; and some of their best commentators have striven elaborately to prove their point. The best of the Turkish critics, Ferydoun and Soudy, have taken the same view.

The works of Hafiz were collected after his death. This collection, called the *Dyvan*, was undertaken by Seid-Kacem-Anvary, himself a distinguished author. According to the best MSS. the *Dyvan* contains 571 odes or ghazels. The edition of Hafiz published at Calcutta in 1791, however, only contains 557 of these ghazels, and seven *Kassydehs*, or Elegies. The first European who called attention to the poetry of Hafiz was the celebrated orientalist Hyde, in his *Syntagma Dissertationum.* But it was not till Rewaski and Sir William Jones almost simultaneously published, the former his *Specimen Poeseos Asiaticæ*, &c., at Vienna in 1771, and the latter his *Commentarii Poeseos Asiaticæ*, that the curiosity of the scholars of the West was fairly roused. The whole *Dyvan* has since been translated into German by Von Hammer, Tübingen, 1812. Richardson, the author of the Persian Dictionary, published *A Specimen of Persian Poetry, or Odes of Hafiz*, with an English translation and paraphrase, chiefly from the *Specimen Poeseos Asiaticæ* of Baron Rewaski; Lond. 1774. Nott has published *Select Odes of Hafiz, translated into English verse;* Lond. 1787: and Hindley a somewhat similar work in 1800. (*Biograph. Univers.;* Ersch. and Gruber's *Encyclopädie.* Wilken's *Chrestomathia Persica*, Leipzig, 1805, contains the life of Hafiz by Daulet-Shah; which is also to be found in Silvestre de Sacy's *Notices et Extraits des Manuscrits* *de la Bibliothèque du Roi*, vol. iv. Much valuable information on the life and writings of Hafiz is to be found in the pages of the *Asiatic Journal, passim.*)

HAGARENES, or HAGARITES, the descendants of Ishmael the son of Hagar. They were also called Ishmaelites; but these appellations have in later times been lost in the general one of Saracens, or Arabians. They dwelt, according to Pliny, in Arabia Felix; Strabo places them in Arabia Deserta; while other writers have assigned them to Arabia Petræa. (Comp. Psalm lxxxiii.; 1 Chron. v. 10.) See ARABIA, vol. iii., p. 361.

HAGEN, a town of Prussia, capital of a cognominal circle in the Arensberg government, Westphalia, 26 miles from Arensberg. It has manufactures of woollen, linen, and cotton stuffs; leather, paper, hats, and iron ware. In the vicinity is an alabaster quarry. Pop. (1849) 5238.

HAGERSTOWN, a town in the United States of North America, capital of Washington county, state of Maryland, near the W. bank of the Antietam Creek, 9 miles from the Potomac River, and 65 miles W.N.W. of Baltimore. It is the southern terminus of the Franklin railway, is well built, and a place of considerable trade. Pop. (1850) 3884. There are several villages of this name in the United States.

HAGGAI, one of the minor prophets, whose history is unknown. He was the first of the three prophets who prophesied in Palestine after the Captivity, and, as Ewald conjectures, it is probable that he had seen the first temple. His style is rather prosaic, with a somewhat artificial rhythm and frequent use of interrogation.

HAGIOGRAPHA (*sacred writings*), a term applied to designate those books of Scripture, which, according to the Jewish classification, held the lowest rank in regard to inspiration. These are the books of Ruth, Psalms, Job, Proverbs, Ecclesiastes, Song of Solomon, Lamentations, Daniel, Esther, Ezra, and Chronicles. This is the common order, but not universally followed. There are few if any traces of this division till after the Christian era.

HAGUE, THE (Dutch *'s Gravenhage*, French *La Haye*), a large and beautiful city of Holland, the usual residence of the court, and the seat of the States-General, or Dutch parliament. It is the capital of the province of South Holland, standing 2 miles from the sea, 37 miles S.W. of Amsterdam, and 13 miles N.W. of Rotterdam, and connected by railway with both of these cities. The Hague originated in a hunting seat, which, as early as 1250, became a palace of the Counts of Holland. It takes its name 'sGravenhage (Counts' Hedge) from the house originally forming part of the inclosure surrounding the Counts' Park. It became the seat of the government and continued so till the erection of Holland into a kingdom by Bonaparte when Amsterdam was substituted. On the return of the Prince of Orange in 1813 it was restored to its former position. Though it was thus early a place of importance, yet it was only a mere village, having neither walls nor corporation till Louis Bonaparte, in the early part of this century, conferred on it the rank and privileges of a city. It is still unfortified, being surrounded only by a moat crossed by drawbridges. The streets are regular and spacious, and several of them are traversed by canals and planted with rows of trees. The houses are large and stately; and altogether the Hague is considered one of the finest cities in Holland. It is neither a trading nor manufacturing town, the inhabitants being chiefly people of means, or dependent on the court and government establishments. The principal streets are the Voorhout—lined with trees and bordered with handsome hotels—the Prinssengracht, Kneuterdijk, and Noord Einde. The Vijverberg (hill of the fish ponds) is a square or place with avenues of trees forming a shady promenade on the one side, and on the other a spacious basin of water. On one side of the Vijverberg stands the Binnenhof, an irregular building of various dates, with a handsome Gothic hall, the only remaining portion of the original residence of the Counts of Holland. The States-General hold their meetings in the Binnenhof, part of which is also occupied by the government offices. The National Museum occupies the former palace of Prince Maurice, an elegant building of the seventeenth century. In the lower story of the building is the Royal Cabinet of Curiosities, several apartments being entirely occupied with objects of curiosity from China, Japan, and the Dutch colonies—those from Japan being peculiarly interesting and varied. One division is devoted to historical relics of distinguished persons. The picture-gallery in the same building is almost entirely confined to the works of the Dutch masters, but it contains some of the finest of these. The Royal Library contains about 100,000 vols., and has also an extensive and valuable collection of medals and gems. The royal palace is an unpretending building in the Grecian style, consisting of a centre and two wings forming three sides of a square. The palace of the Prince of Orange is a large but plain edifice. The splendid collection of pictures belonging to the late king was sold by auction in 1850. There are many valuable private collections of pictures at the Hague, and numerous learned and benevolent associations. It has also fourteen churches, two synagogues, orphan asylum, theatre, and state prison. In the neighbourhood of the town are numerous elegant villas. The summer palace of the royal family, known as the House in the Wood, stands in a finely wooded park in the outskirts of the town. The water in the canals at the Hague is more stagnant than in almost any other part of Holland, and hence frequently arise offensive smells. Huygens, the inventor of the pendulum clock, and William III. of England, were natives of this town. Pop. (1850) 72,467.

HAGUENAU, a town of France, department of Rhin-Bas, and arrondissement of Strasbourg on the Moder, 15 miles N. of Strasbourg. It was originally fortified by Frederick Barbarossa, and is still surrounded by old walls and a ditch. Its principal edifice is a fine old Gothic church. It has a cavalry barrack, civil and military hospitals, a synagogue, and a female penitentiary; manufactures of woollen cloth, earthen-ware, soap, &c.; and oil, madder, and cotton mills. Pop. 10,500. The adjacent forest of Haguenau is one of the largest in France.

HAHNEMANN, SAMUEL, the founder of Homœopathy. See HOMŒOPATHY.

HAICTITES, a Mussulman sect, who attempt to unite their faith with the religion of Christ, and expect his second coming to judge the world; quoting from the Koran these words—"O Mohammed, thou shalt see thy Lord, who will come in the clouds."

HAIL, the natural phenomenon of vapour condensed and congealed by sudden and intense cold in the higher regions of the atmosphere. See ELECTRICITY, vol. viii., p. 586, and PHYSICAL GEOGRAPHY.

HAILSHAM, a small market-town of England, county of Sussex, 58 miles S. by E. of London. It has a large church, with an embattled stone tower, and a market is held every alternate Wednesday. Pop. of parish (1851) 1825.

HAINAN, a large island in the Chinese Sea, lying S. of the province of Canton, to which it is annexed, and separating the Gulf of Tonquin from the Chinese Sea. It is separated from the southern extremity of the province of Canton by the strait of Luichan, 15 or 16 miles wide, and lies between N. Lat. 18. 10. and 20. 54., and E. Long. 108. 25. and 111. It is about 150 miles in length by 100 in breadth, and has an area of above 12,000 square miles. The interior of the island is mountainous: some parts of it rise above the snow line, and it is inhabited by aboriginal tribes. The Chinese inhabitants are mostly descendants of emigrants from Fokien, and are agricultural, trading, or piratical in their vocation, according to circumstances. The soil is mostly sandy, but some of the plains, particularly on the W. coast, are of great fertility. Timber constitutes its most valuable product, the sides of the mountains being covered with extensive forests of sandal, rose, braziletto, ebony, and other trees. Its other products are chiefly rice, sugar, tobacco, indigo, cotton, sweet potatoes, and various fruits. Wax also forms an important article of export; it is produced by an insect called the pelatchung, or white wax insect, when laying its eggs. Hainan is divided into 13 districts. The capital Kiungchanfu is a very populous town, at the mouth of the Limu River, on the Luichan, and has an excellent harbour. Several of the other towns are very populous. The island is said to contain about 1,500,000 inhabitants.

HAINAULT, or HAINAUT (German *Hennegau*), a frontier province of Belgium. See BELGIUM.

HAINBURG, or HAIMBURG, a town of Austria, on the right bank of the Danube, 27 miles E.S.E. of Vienna. It is a place of some trade, and has the largest imperial tobacco manufactory in Austria. Pop. about 4000.

HAINICHEN, a town of Saxony, circle of Leipzig and bailiwick of Nossen, on the Little Striegitz, 40 miles S.E. of Leipzig. The inhabitants are chiefly engaged in the manufacture of woollen and cotton stuffs and in bleaching. The poet Gellert was born here. Pop. (1849) 5855.

HAIR, the delicate filamentous processes which constitute the covering of the skin in mammals generally; and which likewise appear in animals of the lower orders, indeed in all animals that have a true epidermis. It is distinctly developed in the soft-skinned insects, such as butterflies and caterpillars, spiders, bees, &c.; and occurs in tufts in certain parts of the crustaceous animals, as on the feet, jaws, &c. Hair, in its mechanical nature, may be regarded as a condensed form of cuticle. The feathers of birds may be considered as analogous to hair; while the only two classes of animals that are wholly devoid of any kind of hair are the fishes and reptiles. The variety in the conformation of hair is very great, ranging from the finest wool to the quills of the porcupine, or the horn of the rhinoceros, which last is nothing more than an assemblage of many hairs in one compact mass.

But it is to hair, commonly so called, and more particularly to that of man, that we would now direct attention. The human skin is entirely covered with hairs of different degrees of fineness, except on the palms of the hands and the soles of the feet. Each hair originates in the cellular membrane of the skin, from a small bulbous root, which, by the intervention of its vessels, connects it with the *corion* in which it is imbedded. A small portion of the lower end of the hair is hollow, and contains a pulpy matter which is intended for its nutrition; but this cavity never, in common hairs, extends as far as the external surface of the skin. The hair, in a healthy state, is insensible; the pain which is felt on its extraction arising from the nerves which surround the root; yet when in the abnormal condition of what is called *plica polonica*, it becomes sensitive to a high degree, and even bleeds when cut. Among many of the lower animals the hair (though insensible in itself) serves as a very delicate medium of sensation. The slightest touch, even that produced by a human hair, is sufficient to make such animals as cats contract their skin, and by a tremulous motion of their bodies rid themselves of anything adhering to it.

The form of the human hair is rarely cylindrical. It appears to be so only in the straight hairs. In curled hair the transverse section is elliptical; and occasionally it exhibits a bean-like form, arising from a furrow that passes lengthwise down one side of the hair. The flattened form seems in general to be necessary to the curling of the hairs, while the cylindrical figure is opposed to it. In the crisp woolly hair of the negro a very marked flattening is observed, the hairs being sometimes as much as two-thirds broader in one direction than in the other. In the wool of the sheep, which appears to approach the cylindrical form, the phenomenon of curling is probably due to the transverse inequalities with which the surface of the hairs is furrowed. Human hair possesses a very remarkable degree of strength, compared with its small diameter, is considerably extensile, and highly elastic. Saussure found that a human hair, when freed from grease by maceration in an alkaline solution, formed a very delicate hygrometer, from its property of elongating on absorbing moisture. The colouring matter of the hair appears to reside in an oily fluid, analogous in its nature to that which is contained in the *rete mucosum* of the skin; and according to its colour arises the diversity of black, brown, fair, and red hair, and their several shades. Grayness is induced by a deficiency of this fluid, whether arising from age, sickness, or excessive mental emotion, such as grief, or sudden terror. The hair of the head, in particular instances, has been known to attain a length of seven or eight feet. Though hair, in a healthy state, grows only on the external parts of the body, instances have occurred in which it has been formed inside the body in diseased parts. It is also a curious fact that hair will sometimes continue to grow for a certain period after death.

As the hair is a very conspicuous object, and susceptible of much graceful adornment, its arrangement has always been one of the most important duties of the toilet. In scarcely anything has the caprice of fashion been more strikingly displayed than in the various forms which the tastes of different nations and ages have prescribed for disposing this natural covering of the head. The ancient Greeks allowed their hair to grow to a great length; and their natural fondness for this attribute of beauty has been perpetuated by their poets and sculptors alike. The early Egyptians again, who were proverbial for their habits of cleanliness, removed the hair as an incumbrance. All classes among that people, including the foreign slaves, were required to submit to this custom (Gen. xli. 14); and in place of nature's covering they made use of wigs, the reticulated texture of the ground-work on which the hair was fastened allowing free ventilation, while the hair effectually protected the head from the sun (Wilkinson, *Anc. Egyptians*, iii. 354). The Hebrews, on the other hand, esteemed fine hair as a great beauty, and particularly deprecated baldness. Though among the males it was usually kept short, the Hebrew women gloried in their luxuriant tresses, plaiting them and adorning their heads with ornaments of gold and silver and precious stones (Isaiah iii.) The misfortune of Absalom shows that men sometimes indulged in the effeminacy of long hair; and Josephus relates (*Antiq.* viii. 7), that Solomon's horse-guards daily strewed their heads with gold dust, which glittered in the sun. Artificial hair was used not only by the Egyptians, but also by the Greeks, the Carthaginians, and especially by the Romans, among whom the sale of human hair, particularly the blond hair of Germany, was an ordinary species of traffic. Dyeing the hair, too, was much practised by the Romans; and a kind of gold dust was used by ladies who did not adopt borrowed locks. The Roman ladies (as inferior in this respect to the Greeks as in all matters of taste) delighted to pile up the hair tower-like on the top of the head, while they had several rows of curls arranged formally round the sides, and sometimes pendant curls in addition. Fashion also regulated the style of wearing the hair among men in the later times of Rome. A boy's hair, for instance, was cut for the first time at seven years of age, and again at fourteen. On the introduction of Christianity, the apostles and fathers of the church launched severe invectives against the vanity and extravagance displayed in the dressing of the hair, upon which all the resources of ingenuity and art were exhausted to set it off to advantage, and load it with the most dazzling finery. The mimic skill of the *friseur* was frequently called into requisition to represent fanciful devices, such as diadems, harps, wreaths, emblems of public temples and conquered cities, or to plait it into an incredible number of tresses, which were often lengthened by ribands so as to reach to the feet, and loaded with pearls and clasps of gold.

From the great value attached to a fine head of hair, there arose a variety of superstitious and emblematical observances—such as shaving parts of the head, or cropping it in a particular form; parents dedicating the hair of infants to the gods; young women theirs at their marriage; warriors after a successful campaign; sailors after deliverance from a storm; hanging it on consecrated trees, or depositing it in temples; burying it in the tombs of friends, as Achilles did at the funeral of Patroclus; besides shaving, cutting off, or plucking it out, or allowing it to grow in sordid negligence, in token of affliction or calamity.

Among the northern nations, as the Danes, Gauls, and Anglo-Saxons, long and flowing hair was held in great estimation; and the cutting it off was inflicted as a punishment for various offences. Pope Anicetus (A.D. 155) forbade the clergy to wear long hair—an injunction obeyed not without much reluctance on the part of many. Long and flowing hair was so universally esteemed that the tonsure of the clergy was regarded as an act of mortification and self-denial. Some of them who affected the reputation of superior sanctity, inveighed with great bitterness against the long hair of the laity; and this continued long to be a topic of declamation among the clergy, who even represented it as one of the greatest crimes, and a certain mark of reprobation. Anselm, archbishop of Canterbury, went so far as to pronounce sentence of excommunication against all who wore long hair. Serlo, a Norman bishop, acquired great honour by a sermon he preached before Henry I., A.D. 1104, against long and curled hair, by which the king and all his courtiers were so deeply affected that they consented to resign their flowing ringlets, of which they had been so vain. The prudent prelate gave them no time to change their minds, but immediately pulled a pair of shears out of his sleeve and performed the operation with his own hand.

When Julius Cæsar vanquished the Gauls he made them cut off their hair in token of subjection, the cropped head being the badge of slavery. Among the Frankish kings it was long, says Gregory of Tours, the peculiar privilege of the blood royal to have flowing locks; while for all other persons there were gradations in the length and peculiar cut of the hair according to rank, from the noble down to the close-cropped slave. When a prince was excluded from the right of succession to the crown, his long locks were shorn to denote that he was reduced to the condition of a subject. From the time of Clovis the French nobility wore the hair short; but as they grew less martial they allowed it to grow longer. Long hair was the prevailing fashion at the court of Francis I., when that king, proud of the wound on his head, appeared with short hair, and thereupon that style became general. Long hair again came into vogue in the reign of Louis XIII.; and as curling was found inconvenient, wigs became fashionable. Then followed the reign of hair-powder, periwigs, and perukes of enormous dimensions, which, together with many other things no less preposterous, were swept away in the tide of the great French Revolution.

Hair manufactures.—The various uses to which hair is applied are familiar to every one. The most valuable kind is human hair. It is procured chiefly from the north of France, Belgium, and Germany. The lighter coloured hair, which bears the highest value, is the production of Germany; the darker shades are imported from France, where a peasant girl will sell the hair off her head without any sense of degradation; whereas in England this traffic is resorted to only by females of the lowest class. Indeed so common is the practice in France, that agents are employed to traverse certain districts annually at a particular season for the purpose of collecting the crops of human hair which are assiduously cultivated for the sake of the purchase-money, or its equivalent in gewgaws. The wholesale price of human hair varies from 30s. to 60s. per lb., and occasional specimens are of much higher value. A head of hair, such as is bought of the peasant girls in the districts above named, weighs from $1\frac{1}{2}$ to $1\frac{3}{4}$ pounds.

The hair used for weaving consists of the long hair from horses' tails. It is procured principally from South America and from Russia. All the black and grey hair is dyed for the manufacture of black hair-cloth for covering furniture. The white is reserved for dyeing of the brighter hues, such as green, claret, crimson, &c. The quality of the cloth, as well as the brilliancy and permanency of the colours, depend in a great degree on the nature of the warp, which may be either of cotton, linen, or worsted. In the manufacture of hair-cloth, either plain or damasked, the weaver uses a sort of hook-shuttle, which he passes between the threads of the warp, or shed, towards his left hand; the assistant, or "server," places a single hair over the end of the hook, and the weaver draws it through the warp. The placing of the hairs one by one renders this a tedious operation, and one that does not admit of the application of machinery, which is so advantageously employed in fabrics where the shot or weft consists of a continuous thread.

Hair or *Down* of plants. See Botany, vol. v., p. 75.

Hair-Powder, a substance used to whiten the hair, consists generally of pulverised starch, with the addition of some perfume. This mode of disguising the colour of the hair has fallen into almost complete desuetude, yet the old tax of L.1, 3s. 6d. a-year is still exacted from every one using hair-powder.

HAKE, a kind of fish, the *Gadus merluccius*, common in the English seas and the Mediterranean, and often prepared as stock-fish. See index to Ichthyology.

HAKLUYT, Richard, a celebrated naval historian, descended from an ancient family at Eton or Yetton, in Herefordshire, is supposed to have been born in London about 1553. He was educated at Westminster School; and thence, in 1570, he removed to Christ Church College, Oxford, where he applied himself particularly to the study of cosmography, and read public lectures in that science. When Sir Edward Stafford was sent ambassador to France in 1583, Hakluyt attended him, probably in the capacity of chaplain. He was at this time master of arts and professor of divinity. In 1585 he obtained the royal mandate for the next vacant prebend of Bristol, to which preferment he succeeded during his residence at Paris. Constantly attentive to his favourite cosmographical inquiries, Hakluyt, in searching the French libraries found a valuable manuscript history of Florida, which had been discovered about twenty years before by Captain Laudonière and others; and this he caused to be published in the French language at his own expense. Soon afterwards he revised and published Peter Martyr's book *De Orbe Novo*, with marginal notes, a comprehensive index, and a map of New England and America. After five years' residence in France, Hakluyt returned to England in 1588; and in 1605 he was appointed prebendary of Westminster, which, with the rectory of Wetheringset in the county of Suffolk, seems to have been the summit of his preferment. He died in 1616, and was buried in Westminster Abbey. Hakluyt was an indefatigable and faithful historian, and his various collections are curious, instructive, and interesting, and now command very high prices. His works are—*A Collection of Voyages and Discoveries*, in one small volume; *History of Florida; The principal Navigations, Voyages, and Discoveries of the English Nation, made by Sea or over Land* *to the farthest distant Quarters of the Earth, at any time within the compass of these* 1500 *years*, in three vols. folio; *The Discoveries of the World, from the first Original to the year* 1555, *written in the Portugal tongue by Antonio Galvano, corrected, much amended, and translated into English, by Richard Hakluyt; Virginia richly valued, by the Description of the Main Land of Florida, her next neighbour, written by a Portugal gentleman of Elvas, and translated by Richard Hakluyt.* Besides these, he left several manuscripts which were printed in Purchas's collection.

HAL, a town of Belgium, province of South Brabant, on the Senne and the Charleroi Canal, 10 miles S.S.W. of Brussels. It has a fine old Gothic church of the fourteenth century, with a famous miracle-working image of the Virgin. The high altar of sculptured marble is said to be unequalled in the Netherlands. Pop. (1851) 7392.

HALAS, a market-town of Hungary, district of Little Cumania, on Lake Halasto, 80 miles S.S.E. of Pesth. It has a considerable trade in corn, wine, and cattle, and about 10,000 inhabitants.

HALBERSTADT, a town in the Prussian province of Saxony, government of Magdeburg, and capital of a circle of the same name, on the Holzemme, a tributary of the Bode, 29 miles S.W. of Magdeburg, with which it communicates by railway. This is a very ancient town, and was the seat of a bishop as early as 814. The cathedral is a remarkable edifice, chiefly in the pointed Gothic style, erected between 1235 and 1491, except the lower part or the west front, which is older. It contains some valuable paintings and antiquities; and the collection of episcopal and priestly robes, from the twelfth to the sixteenth century, is perhaps the finest in northern Europe. The church of Our Lady is a building in the Byzantine style, dating from the beginning of the eleventh century, and has recently been restored. The town proper is surrounded by walls, outside of which are several suburbs. It has in general an antique appearance, and contains some old curiously ornamented timber-framed houses. Halberstadt is the seat of a superior court of justice, and has a gymnasium, normal school, school of obstetrics, deaf-mute institution, orphan asylum, public library, theatre, &c. It carries on a considerable trade, and has manufactures of woollen cloths, gloves, carpets, leather, starch, tobacco, and beer. Pop. (1849) 19,840.

HALBERT, or HALBERD, an ancient military weapon now rarely to be seen except in armouries, or on ceremonial occasions. It was designed both for cutting and thrusting, being a kind of combination of the spear and battle-axe, with great variety in the shape of the head, but always terminating in a point or blade, and having a shaft five or six feet in length. The halbert was formerly borne by sergeants of foot and artillery, and by the guards of the great officers of the army; and there were also companies of halberdiers to protect the colours. This weapon was likewise known as the *Danish axe;* having passed from the Danes to the Scots, and from them to the English Saxons, from whom it passed to the Normans; though Meyrick (*Hist. of Anc. Arm.*) supposes it to have been a Swiss invention, borrowed by the French under Louis XI., and first used by the English in the reign of Henry VIII. This apparent discrepancy, however, may perhaps be annulled on the supposition of the use of weapons not very dissimilar at different periods under other names. The word *halbert* is formed from the Teutonic *hal*, hall, and *bard*, a hatchet, as being the weapon appropriated to warders. Vossius fancifully derives it from the German *hallebaert*, a compound of *hel*, clarus, splendens, and *baert*, axe.

HALCYON, the ancient name of the alcedo or kingfisher.

HALCYON DAYS, in *Antiquity*, a name given to seven days before and as many after the winter solstice; because at this season the halcyon, invited by the calmness of the weather, laid its eggs in nests built close by the brink of the sea; and hence the phrase *halcyon days* is expressive of times of peace and tranquillity.

> "As late they love: their nuptial faiths they show.
> Now little birds ingender, parents grow:
> Seven winter dayes with peacefull calme possest,
> *Alcyon* sits upon her floating nest."—Sandy's *Ovid. Met.* b. xi.

HALDANE, ROBERT and JAMES ALEXANDER, were the sons of Captain James Haldane of Airthrey, and Katherine, daughter of Alexander Duncan, Esq. of Lundie, and sister of Lord Duncan, the hero of Camperdown. Robert was born in 1764, and his brother in 1768. Two weeks before the birth of the latter their father died, and they did not long enjoy the benefits of a mother's care. In 1774 she also was removed; but during the short period in which she was allowed to exercise her maternal duties, she discharged them with admirable fidelity and tenderness; and her pious instructions made a deep and indelible impression on their youthful minds. The charge of the orphans now devolved upon their maternal grandmother and uncles, who did all they could to supply a mother's place. Under their direction, the education of the boys was carried on first at Dundee, and subsequently at the High School and University of Edinburgh, where they proved themselves to be possessed of excellent abilities, and made respectable progress in their studies. At the age of seventeen both Robert and James went to sea, and from this point we shall notice the leading events of their lives separately. In 1780 Robert entered the royal navy, served in the Foudroyant under Captain Jervis, afterwards Earl St Vincent; and during the memorable night engagement with the Pégase, distinguished himself so much by his ability, energy, and intrepidity, that Captain Jervis wrote his uncle a letter of congratulation, predicting the eminence of his nephew. At the peace in 1783 Robert retired from the navy. He was then in his twentieth year. In 1785 he married Katherine Cochran Oswald, second daughter of the late George Oswald, Esq. of Scotstown, and soon after settled on his beautiful estate of Airthrey, in the neighbourhood of Stirling, in the improvement of which he spent the most of his time for several years. The stirring events of the French Revolution also occupied much of his attention. He disapproved of the war with France in which Britain was engaged, and gained himself many enemies by stating this boldly at a meeting of the freeholders of the county of Stirling. He was afterwards often charged with holding the most violent and democratic views; but these charges were wholly without foundation. It is true, however, that he did sympathize with the revolutionary movements of the French, and expected benefits to flow from them which were never realized. And he tells us that the disappointment he felt on this account contributed in no small degree to hasten and mature a vital change that was going on in his own mind, and led him to confess and submit to that Supreme Power by whose influence alone individuals and nations can be regenerated. The forms of religion he had indeed never cast off; but it was not till now that he was awakened to a clear perception of its impressive and momentous realities. No sooner were these opened to his view than he, with characteristic energy, devoted himself to the pursuit of truth, sincerely desirous to find and follow it wherever it led him. He read much, and thought deeply, on the evidences of Christianity, and carefully studied the records of divine revelation. The issue of his studies was a profound conviction that the Christian religion was from above. He now resolved to consecrate his time, talents, and wealth to the advancement of Christianity. His motto was, "Christianity is everything or nothing. If it be true, it warrants and commands every sacrifice to promote its influence.

If it be not, then let us lay aside the hypocrisy of professing to believe it." A report of the Baptist missions which fell into his hands, excited his sympathy toward the heathen population of India. A vast missionary scheme was formed on their behalf, several eminent missionaries were appointed, and this staff was to be supplemented by catechists and schoolmasters, and provided with a printing establishment. The entire expense was undertaken by Mr Haldane; and in order to supply the requisite means, and be ready to depart without delay, his fine estate was sold. But the East India Company refused to sanction the scheme, and he was therefore obliged most reluctantly to abandon it. Other fields of usefulness, however, were open to him, and to these he turned. At his expense many chapels were hired, and many erected, throughout Scotland; and many pious young men supported and educated for the ministry. Nor was the exercise of his Christian philanthropy confined to his own country. In 1816 he visited the Continent for the same end; and first at Geneva, and then at Montauban, was occupied night and day in expounding the gospel to all who would listen, and especially to those who either were ministers or were under training for that profession. These pious labours were attended with remarkable success. After a sojourn on the Continent of nearly three years Mr Haldane returned to Scotland, and spent the remainder of his days either in Edinburgh or on his estate of Auchengray, which he had purchased in 1809. In all good works he continued to the last to manifest unwearied zeal and undiminished liberality; and from whatever quarter divine truth was assailed, it always found in him an able and uncompromising champion. In December 1842 this good man rested from his labours. His writings were numerous; the chief are—his work on the *Evidences and Authority of Divine Revelation*, and his *Commentary on the Epistle to the Romans*.—We now resume the narrative of James Haldane's life. In 1785 he went to sea, and entered the East India Company's service, with which his family had been connected for several generations. He was an enthusiast in his profession, and became an intrepid and skilful seaman. After the completion of his fourth voyage in 1793 he was appointed captain of the Melville Castle, and had the sure prospect of soon acquiring an ample fortune. In the same year he married the only daughter and child of Major Joass of Culleonard in Banffshire. Instead of putting to sea immediately as was intended, the Melville Castle was unexpectedly detained for months. Meanwhile he was led to study the Bible more carefully than he had ever done before. He then, under deep religious impressions, threw up his naval command with all the worldly advantages which it promised, and settled in Edinburgh. Like his brother, whatever he did, he did with all his might. The low state of religion in his own land, and the prevalence of error and immorality, he most earnestly began to counteract. They distributed tracts, opened Sabbath-schools, and proclaimed the Word of God to all who would hear them, first in the neighbourhood of Edinburgh, and then throughout all Scotland. As a preacher James Haldane met with the greatest success. He attracted large audiences wherever he went; and there were few towns, or even villages, of his native country to which his missionary labours did not extend. In churches or halls, when accessible, or, if not, in the market-place or adjoining field, and often in the face of obloquy, derision, and under the most violent threats and opposition, he calmly and resolutely persevered in his work. Besides these itinerant labours, he discharged gratuitously the duties of pastor to a congregation in Edinburgh, to which he was ordained in 1799. This charge he held till his death. As a minister he was a bright example of fidelity and zeal, and always ready to lend his aid in the promotion of every good work. But his labours were not confined to one locality. With James Haldane, as with his brother Robert, the field to be cultivated was the world; and wherever a door of usefulness was open, his voice and pen were ready to be employed. His zeal and activity remained undiminished; and when above fourscore he still preached to his congregation with great regularity. In 1849, the jubilee of his pastorate was celebrated. In 1851 he rested from his labours. Though Baptists from conviction, the Haldanes gave no unseasonable or exaggerated prominence to the peculiarities of their denominational views; but, both by example and precept, made the great fundamental truths of the gospel the grand centre of union among all true Christians. The record of their lives is one of the most interesting of Christian biographies, and, if its lessons and example have their due influence, may be one of the most profitable. (W. B.)

HALDE, Jean Baptiste du, was born at Paris, Feb. 1, 1674, and having entered into the society of Jesus, he was at length appointed to succeed Father Legobien, who had been intrusted with the duty of arranging the letters they received from different quarters of the globe. He was also for some time secretary to the famous Father Letellier, confessor to the king of France. He died Aug. 18, 1743. Du Halde is represented as a man of mild and amiable character, and as remarkable alike for his unaffected piety and unwearied industry. He was the author of some Latin poems of no great value; but is still remembered for the following works:—*Lettres Edifiantes et Curieuses écrites des Missions Etrangères*, which he edited with great ability from the ninth to the twenty-sixth volume inclusive, and which have been translated into English and German. *Description Géographique, Historique, Chronologique, Politique, et Physique, de l'Empire de la Chine et de la Tartarie Chinoise*, Paris, 1735, in four volumes large folio, with figures and an atlas by D'Anville. This work, the first in which China is described with so much exactness and detail, is at the same time a beautiful monument of French typography. The description contained in this work and in the *Lettres Edifiantes* has furnished materials to almost all the modern writers who have treated of that vast empire, and has contributed materially to advance the science of geography. (J. B—E.)

HALE, Sir Matthew, Lord Chief-Justice of England, was born on the 1st of November 1609, at Alderley in Gloucestershire. His father had been a barrister, but having retired from practice, resided upon a small estate he had purchased there. His paternal ancestors appear to have been in the middle rank of life, his grandfather having been a clothier at Wotton-under-Edge; but on his mother's side he was connected with the noble family of the Poyntzes of Acton. The future chief-justice having had the misfortune to lose his parents when he was only in his fifth year, was placed by his guardian under the care of the Rev. Mr Staunton, vicar of Wotton-under-Edge, by whose tuition he became strongly embued with the religious principles of the Puritans. At school he was distinguished by great diligence, and acquired, it is probable, those habits of sedulous application to study, which in subsequent years secured his reputation and advancement. Having acquired a considerable stock of classical learning he was sent to the University of Oxford at the age of sixteen, and became a student of Magdalen Hall under the tuition of Obadiah Sedgwick, a classical scholar of high attainments, and whose religious sentiments were in accordance with those of his former instructor. Here he devoted himself with great steadiness for several terms to the study of the philosophy of Aristotle and the theology of Calvin, with a view to holy orders. Suddenly, however, the diligent and devout student, of whose future eminence in the church his friends had formed the highest anticipations, became smitten with a love of military glory, and resolved to abandon the peaceable profession he had apparently chosen for that of arms. From this purpose he was happily diverted by an unexpected incident. Before proceeding to the Low Countries to take service under the Prince of Orange, he found himself involved in a legal action which threatened to deprive him of his patrimony. It became requisite for him to proceed to London, in order before his departure to give instructions for the defence of his rights. His leading counsel was the celebrated Sergeant Wilde, one of the ablest advocates then at the bar, and this great lawyer must have perceived in the acuteness and sagacity of his youthful client a peculiar fitness for the legal profession; for, understanding that he was bent upon a military career, he laboured with great earnestness to induce him to renounce his purpose and devote himself to the study of law. In this he was at length successful, and Hale became a member of the honourable society of Lincoln's-Inn on the 8th of November 1629.

No sooner did the future chief-justice make choice of the profession on which his talents and character were one day to reflect so great a lustre, than he resumed his habits of intense application. Day after day, month after month, for the long period of eight years he underwent an amount of intellectual labour almost incredible. The rules which he laid down for himself, and which are still extant in his handwriting, prescribe sixteen hours a-day of close application, and prove not only the great mental power, but the extraordinary physical strength he must have possessed, and for which, indeed, during his residence at the university, he had been remarkable. Some idea of his ardour in the acquisition of knowledge may be formed from the fact that, during the period allotted to his preliminary studies, he not only read over and over again all the year-books, reports, and law treatises in print, but at the Tower of London and other antiquarian repositories, examined and carefully studied the records from the earliest period to his own time, in order to acquire a familiar acquaintance with the history, the principles, and the practice of English jurisprudence during every reign since the foundation of the monarchy. Even the *Common-place Book*, which he composed as the result of his study and research, may, according to Lord Campbell, "be considered a *corpus juris*, embracing and methodizing all that an English lawyer on any emergency could desire to know." But Hale did not confine himself to the law alone, although the manner in which he devoted himself to that study might well have occupied his whole time. It was his maxim, that to be master in any profession is impossible without an acquaintance with other sciences. He dedicated, therefore, no small portion of his time to the study of pure mathematics, to investigations in physics and chemistry, and even to anatomy and architecture; and there can be no doubt that the value of many of his decisions arose not more from his legal knowledge than from his extraordinary proficiency in other departments of human learning.

The high character Hale acquired while a law student produced the result which was to be expected. No sooner was he called to the bar than he found himself in full practice; and so completely did he justify the expectations of his friends that in a very few years he was at the top of his profession. The period at which he entered on public life was to be in many respects the most eventful in the history of the English nation, and occurrences were to take place which should result in the establishment of those great political principles on which the liberty and prosperity of the people depend. Hale rose in reputation amid the struggle of parties whose obstinacy could not fail sooner or later to lead to a violent collision; and as he had not openly espoused either side, both were eager to obtain his support. He declared himself neutral, however, resolved to follow the example of Pomponius Atticus, by so acting as to retain the esteem of all parties without being exclusively devoted to any. This line of conduct has been censured by Hale's biographer, Lord Campbell, as "cowardly and selfish;" but a little consideration will readily prove that the censure is not merely too severe, but that it is undeserved. Hale felt that his strength lay not in being a political partizan, but an interpreter of the laws of his country. He was too good a historian, and too sagacious a philosopher not to foresee the necessary result of the impending conflict; and thus in becoming neutral, he probably felt that he adopted a course which enabled him to do the largest amount of good to his country, as well as escape a struggle wholly adverse to his favourite pursuits, and in which he could not engage so as to benefit the party he should attempt to support. Perhaps, too, it may have appeared to him that to keep free from those violent prejudices so apt to distort and confuse the judgment would render him more likely to be useful either as an advocate or a judge.

Hale was counsel in some of the most celebrated trials recorded in English history. It has been said—although not with certainty—that he was engaged for the Earl of Strafford; but he was certainly counsel for Archbishop Laud, Lord Maguire, Christopher Love, the Duke of Hamilton, and others. He was ready to plead on the side of Charles I. when that king was brought to trial before his people; but he was not called upon to do so—his majesty having, by Hale's advice, refused to submit to the court.

The parliament having gained the ascendancy, Hale signed the Solemn League and Covenant, and was a member of the famous Assembly of Divines at Westminster in 1644. His early education, it may be presumed, rendered the views of that assembly by no means disagreeable to him; but he was, nevertheless, moderate in his opinions as to church government; and although he would undoubtedly have preferred a Presbyterian form, he had no serious objection to the system of modified Episcopacy proposed by Archbishop Usher.

Consistently with his desire to remain neutral, Hale took the engagement to the Commonwealth as he had done to the king, and in 1653, having been already elevated to the rank of sergeant, became a judge in the Court of Common Pleas. Two years afterwards he sat in Cromwell's parliament as one of the members for Gloucestershire. After the death of the Protector, however, he declined to act as a judge under Richard Cromwell, although he represented Oxford in Richard's parliament.

Immediately upon the restoration of Charles II., Hale proceeded to Whitehall, and was graciously received by the king. Very soon afterwards he was appointed Chief Baron of the Exchequer; and, owing to his extreme humility, received, with great reluctance, the honour of knighthood at the hands of his sovereign. After holding the office of Chief Baron for eleven years, he was raised to the higher dignity of Lord Chief-Justice. Many interesting anecdotes are related of him which place his character in a most amiable light, and exhibit his marvellous fitness for the difficult office he so worthily filled. On an impartial review of his life, indeed, it is not surprising that Lord Campbell should thus refer to him—"He is certainly to be considered the most eminent judge who ever filled the office (of Chief Baron); and being promoted to be Chief-Justice of England, he gave new dignity to the supreme magistracy which had been illustrated by Gascoigne, by Fortescue, and by Coke." Nor are evidences wanting of the sterling piety by which he was animated. During his long laborious career he never forgot the duties of religion, or failed to illustrate, wherever he had an opportunity by his conduct and conversation, the great principles of Christianity. He was the intimate friend of those great ornaments of the Established Church, Barrow, Tillotson, Wilkins, and Stillingfleet, as well as of the venerable and learned Baxter, the great leader of the Nonconformists; while to all of them, and indeed to all the great

Hales.

and good men of his day, he was the object of love and veneration.

On attaining his sixty-seventh year, the venerable chief-justice found his health so indifferent that he resigned his office; and in Feb. 1676 bade a final adieu to London, betaking himself to his native place, and making his progress thither by easy journeys. On arriving at Alderley, the air of the country and the scenes of his early life for a while revived him, but the relief was only temporary. His disease assumed an aggravated form, and he died on the 25th of Dec. in the same year, having endured his lingering illness with the faith and patience of a saint. He had been twice married, and had outlived all his children but his eldest daughter and his youngest son.

Lord Hale was the author of several works on philosophical and religious or devotional subjects, but (as is much to be regretted) not upon law—the subject on which he was above all his contemporaries capable of writing. In 1673 he published an essay on the *Gravitation of Fluid Bodies;* this was followed soon after by a treatise on the *Torricellian Experiment and the Weight of the Air.* He had likewise printed two volumes of *Contemplations,* consisting of a variety of papers of a religious character; and ultimately he sent to the press his work on *The Origination of Mankind.* This latter work was not published till after his death. He likewise attempted to write poetry, but, it must be admitted, with little success. The studies of a great lawyer are not those that favour the imaginative faculty, so valuable to the votary of the muses. (R. W. F.)

HALES, Stephen, D.D., a distinguished physiologist, was born in 1667 at Beckesbourn in Kent. He was educated at Bennet College, Cambridge, of which, in 1702, he became a fellow. In 1710 he was made perpetual curate of Teddington, near Twickenham, then rector of Porlock in Somersetshire, and afterwards of Faringdon in Hampshire. Despite these preferments, however, he continued to reside at Teddington. In 1718 he became a member of the Royal Society, to whose *Transactions* he contributed a large number of ingenious and valuable papers. In 1753, on the death of Sir Hans Sloane, he was chosen foreign associate of the French Académie des Sciences. He died at Teddington in 1761.

Soon after his election into the Royal Society, Hales published his *Vegetable Statics, or an Account of some Statical Experiments on the Sap in Vegetables,* and has thus the honour of having made the first discoveries in what has since become the great science of vegetable physiology. The work was soon translated into French, Italian, German, and other continental languages, and is still an authority on the subject which it treats. In 1733 he published, under the title of *Hæmastatics,* a similar essay on the circulation of the blood. But the most important services which he rendered to his country were rather those of a practical philanthropist than of a merely scientific observer. One of the most useful of his inventions was his "ventilator," with which he solved the difficult problem of introducing abundant supplies of pure and fresh air into jails, hospitals, mines, and the holds of ships. In 1749 one of these ventilators was fairly tested in the Savoy prison, where the annual average of mortality had been from fifty to a hundred victims. From 1749 till 1752 inclusive, however, only four persons died within the jail, though in 1750 the number of prisoners was 240. Of these four, one died of small-pox and another of delirium tremens. The advantages of Hales' ventilators were thus so fully established that they were immediately adopted by the French government, and applied with success in a far greater number of cases than the inventor had ever contemplated. In 1752 another of these machines was fitted up in Newgate, and the mortality immediately fell in the proportion of 7 to 16. Hales' other inventions were all of an equally practical and useful character. They had reference chiefly to such objects as preserving meats for long sea-voyages, distilling sea-water, cleaning and preserving corn, &c. He also gained the Copley gold medal for his essay on the medicines for dissolving the stone in the bladder.

Halesowen || Halicarnassus.

HALESOWEN, a market-town of England, county of Worcester, in a pleasant valley 7 miles W.S.W. of Birmingham. It consists chiefly of one main street, crossed by several inferior ones. The parish church is a fine building, surmounted by a beautiful spire, and containing several interesting monuments, one in memory of Shenstone the poet, who is buried in the adjacent cemetery. The inhabitants are chiefly employed in the manufacture of nails and the coarser kinds of hardware. Market-day, Monday. In the vicinity is Leasowes, the birthplace and residence of Shenstone. Halesowen was formerly celebrated for its monastery, of which some remains still exist. Pop. (1851) 2412.

HALESWORTH, a market-town of England, county of Suffolk, 100 miles N.N.E. of London. By means of the Blyth and a navigable canal it communicates with the sea at Southwold, about 9 miles distant. It carries on a considerable trade in agricultural produce; hemp is largely grown in the vicinity; and the inhabitants are chiefly employed in spinning yarn, or as maltsters. Market-day, Tuesday. Pop. (1851) 2529.

HALF-PAY. See Commission, *Military;* and Navy.

HALIBUT. See *Holibut,* index to Ichthyology.

HALICARNASSUS, a city of Caria, on the coast of Asia Minor, opposite to the island of Cos, founded by a colony of Trœzenians (Strabo), who were joined by a party of Argeians under the command of Melas and Arvanias (Vitruv. ii. 8). We are told by Herodotus (i. 144), that it originally belonged to the Dorian Hexapolis, and that it lost this privilege because Agasicles, one of its citizens, carried off the tripod, which had been adjudged to him in the games in honour of the Triopian Apollo, instead of dedicating it to the god, as had always been the custom. The other cities, indignant at this breach of the law, met and declared Halicarnassus unworthy of participating in their privileges; and from that time the Dorian confederacy consisted of five cities, and was called Pentapolis. We have no means of discovering at what period this event took place; but about the year 500 B.C. we find Halicarnassus subject to Lygdamis, whose daughter Artemisia commanded a squadron of ships in the fleet of Xerxes, and behaved so nobly in the battle of Salamis, 480 B.C. (Herod. viii. 87.) It was probably during the reign of her son, called Lygdamis, that Herodotus, unwilling to witness the tyrannical acts of a despot, abandoned his native city and retired to Samos. A considerable period now elapses, in which we know nothing of the history of Halicarnassus; but about 350 B.C. we find it under princes of Carian extraction. Hecatomnus is mentioned by Strabo (xiv. 656) as king of the Carians; and he left three sons, Mausolus, Hidrieus, and Pixodarus, and two daughters, Artemisia and Ada, who were married to the two elder brothers. On the death of Mausolus, his wife and sister became queen. She is best known in history as the builder of that celebrated monument in honour of her husband, which she called from him mausoleum, and which was reckoned one of the seven wonders of the world. She was succeeded by her second brother Hidrieus, whose sister and wife Ada was driven from the kingdom by her brother Pixodarus. At this period Alexander the Great arrived with his forces in Caria, and having razed Halicarnassus to the ground, restored Ada to the sovereignty of Caria. It seems to have been rebuilt, but never to have regained its former degree of splendour. Cicero speaks of his brother restoring Halicarnassus (ad. Q. Fr. i. 8), and Tacitus (Ann. iv. 55) tells us that the people of this place were anxious to erect a temple to Tiberius. It was the birthplace of Herodotus, and of Dionysius, author of the Roman Antiquities. Its ruins are still found at Boudroun. The course of the old walls is still pointed out, and traces of the mausoleum are yet to be seen. (See Hamilton's *Researches*, &c.)

HALIEUTICS ('Αλιευτικα, from ἁλιευς, a *fisherman*), the name given to treatises on fishing, or the art of fishing; as the *Halieutics* of Oppian.

HALIFAX, a municipal and parliamentary borough and market-town of England, West Riding of Yorkshire, 36 miles W.S.W. of York. It stands on a gentle acclivity rising from the Hebble, a tributary of the Calder, and is almost entirely surrounded by hills. Though in some parts the streets are narrow and irregular, the improvements of late years have been so great that the town generally presents a new and handsome appearance. A few old plaster houses with carved oak framework, of the reign of Henry VIII., still remain, otherwise the buildings are of stone supplied from quarries in the neighbourhood. The town is well-paved and lighted with gas, and is plentifully supplied with water. It has a number of elegant buildings, principally of modern date. The parish church of St John is a large and handsome edifice of Gothic architecture, erected at different dates, and surmounted by a highly ornamented tower 117 feet in height. Trinity Church, erected in 1795, is a handsome Grecian building with Ionic pilasters, and an elegant tower with dome at its west end. St James's, built in 1831, is in the pseudo-Gothic style, with turrets at the west end. Besides the Episcopal places of worship there are chapels belonging to the Independents, Baptists, Wesleyan and other branches of Methodists, Quakers, Unitarians, and Roman Catholics. It has a number of day, evening, and Sunday schools, including a national, Lancasterian, and a grammar school. There are a number of literary and scientific as well as of charitable institutions. The infirmary is a large and elegant building, with excellent accommodation, and affording medical and surgical aid to outdoor as well as indoor patients. There are also public baths, assembly-rooms, theatre, savings bank, and mechanics' institute. The Piece Hall is a magnificent quadrangular structure occupying more than two acres of ground, and having 315 rooms for the lodgment of goods which are open for sales once a-week.

Halifax derives its importance from the manufacture of cloth, which was commenced here in the beginning of the 15th century. It now ranks next to Leeds and Bradford as a seat of the woollen and worsted manufactures. The principal staples are shalloons, camlets, figured vestings, moreens, bombazines, crapes, russets, serges, baizes, coatings, broad and narrow cloths, kerseys, cottons, and silks. A considerable number of persons are employed in making machinery. The situation of Halifax is also favourable to the development of its industry, having canal communication with the River Calder and the Rochdale Canal, and being connected by railway with Manchester and Leeds. According to an old law, the magistrates of Halifax were invested with the power of inflicting capital punishment on any thief taken "hand-habend," "back-berend," or "confessand," to the value of 13½d. The execution took place on the first market-day after conviction, by means of an instrument somewhat resembling the guillotine. Halifax is governed by a mayor, ten aldermen, and thirty councillors, and returns two members to Parliament. The parish of Halifax is one of the largest in the kingdom, having an area of 75,740 acres, and containing (1851) 149,257 inhabitants. Pop. (1851) of borough, 33,582. Registered electors, 1200.

HALIFAX, a city and seaport of British North America, on the S.E. coast of Nova Scotia, of which it is the capital. It stands on the declivity of a hill about 250 feet in height, and rises gradually from the S.W. side of a deep inlet of the sea, called Halifax Harbour. It is about two miles in length by nearly a mile in breadth, and consists mostly of wide and regular streets. "The appearance of Halifax from the water, or from the opposite shore, is prepossessing and animated. The front of the town is lined by wharfs, alongside which vessels of all sizes, and variously rigged, are incessantly loading or discharging their cargoes. Warehouses rise over the wharfs, as well as in different parts of the town; and dwelling-houses and public buildings rear their heads over each other as they stretch along and up the sides of the hill. The spires of different churches, the building above the town in which the town-clock is fixed, a rotunda-built church, the signal-posts of Citadel Hill, the different batteries, the variety of style in which the houses are built, some of which are painted white, some blue, and some red; rows of trees showing themselves in different parts of the town; the ships moored opposite the dockyard; the establishments and tall sheers of the latter; the merchant vessels under sail, at anchor, or alongside the wharfs; the wooded and rocky scenery of the background; with the islands, and the small town of Dartmouth, on the E. shore,—are all objects which strike most forcibly on the view of a stranger." (M'Gregor's *Brit. America*, i. 325.) The houses are mostly of wood plastered or stuccoed, and have, in many cases, an imposing and elegant appearance; but a number of the private houses and the public buildings are of stone. The government house is a solid, sombre-looking structure at the south end of the town, and the admiral's house is a plain stone building at the north end. The province building, near the centre of the town, is a magnificent structure, 140 feet long by 70 broad and 45 high, with a fine Ionic colonnade. It comprises chambers for the council and legislative assembly, the supreme court, and the various provincial offices. The dockyard is one of the largest and best stored in the British colonies, and covers an area of 14 acres. The harbour extends inland from the Atlantic for 15 miles, terminating in a beautiful land-locked expanse of water called the Bedford Basin, and capable of accommodating the whole British navy. The entrance to Halifax harbour is well lighted, and buoys are placed upon all the shoals. A fine deep channel stretches up behind Halifax, called the Northwest Arm, which renders the site of the city a peninsula. On the west side of the entrance to the harbour, on a small island off Sambro Cape, is Sambro Lighthouse, with a fixed light 210 feet high. A detachment of artillery, with two 24-pounders, is stationed here for firing at regular intervals during the dense fogs which are prevalent on this coast. After passing Sambro light, the course for large vessels is between the mainland on the W. and Macnab's Island on the E.; on a point projecting from the latter a lighthouse has recently been constructed. Opposite the town the harbour is rather more than a mile in width, whence it gradually narrows to about one-fourth of that width, and then suddenly expands into a magnificent basin. The harbour is accessible at all times, and is rarely impeded by ice. It is defended by forts and batteries. Halifax is the seat of a considerable fishery. Its principal trade is with Great Britain, the British colonies, and the United States. In 1852 the total exports from Halifax valued L.588,206, of which L.20,167 went to Britain, L.144,480 to British West Indies, L.234,842 to British North America, L.119,385 to United States, and L.69,332 to other countries; the total imports during that period valued L.939,864, of which L.399,277 came from Britain, L.11,496 from British West Indies, L.162,955 from British North America, L.218,817 from United States, and L.147,319 from other countries. The imports are chiefly British manufactures and native products of the West Indies and United States; the exports, dried and pickled fish, timber, cattle, agricultural and dairy produce, fur, whale and seal oil, &c. Mail-steamers run every alternate week between Liverpool, Halifax, and Boston, and there is regular communication, by steamers and sailing vessels, with all the great ports of the United States, British America, and the West Indies. A canal has been cut across the country from Halifax to the basin of Minas at the bottom of the Bay of Fundy. In 1790 Halifax contained only 700 houses and 4000 inhabitants. In 1817 it was declared a free port, and had then 1200 houses. In 1844 it had 22,000 inhabitants, and in 1852, 26,000.

HALIFAX, MARQUIS OF. See SAVILE, *Sir George*.

HALIMASS (Saxon, *halig*, holy, and *mass*), the feast of All Souls. See HALLOWMASS.

HALL, a town in the Austrian province of Tyrol, circle of the Lower Inn, on the left bank of that river, by means of which it communicates with Vienna. It occupies a picturesque situation between two mountains, is surrounded by walls, and has a fine old Gothic church. It has very extensive salt-works, with some linen and cotton factories. Pop. about 5000. There are several smaller towns in Germany of this name.

HALL, or *Suabian Hall*, a town of Würtemberg, circle of Jaxt, on the Kocher, 35 miles N.E. of Stuttgard. It was formerly a free imperial city, and is surrounded by strong walls, defended by towers and ditches. It has a town-hall, seven churches, a gymnasium, and two public libraries. It is chiefly famous for its extensive salt-works, supplied from saline springs in the vicinity. Sugar, soap, starch, are its other products. It has also a large trade in cattle. Including the three suburbs, it has about 6500 inhabitants.

HALL, in *Architecture*, a large apartment at the entrance of a house or palace.

HALL is also applied to an edifice where courts of justice are held, as Westminster Hall, in connection with which are the courts of Queen's Bench, Chancery, Common Pleas, Exchequer, the Rolls Court, and the Vice-Chancellor's two courts.

HALL, CAPTAIN BASIL, a distinguished British traveller and miscellaneous writer, was born at Edinburgh in 1788. His father was Sir James Hall of Dunglast, a man still remembered for his Essay on the *Origin, Principles, and History of Gothic Architecture*, and for his ingenious researches into geology, with a view of establishing the theory of Hutton in opposition to that of Werner. Basil Hall entered the navy in 1802, and rose gradually to be post-captain in 1817. In the course of his many voyages, he set himself to observe the manners and customs of the peoples whom he visited, as well as the physical peculiarities of the countries which they inhabited, and in this way collected the materials for a very large number of scientific papers which he contributed to various journals and encyclopædias. Perhaps the most interesting of his works is his *Voyage of Discovery to the Western Coast of Corea and the Great Loo-Choo Island, in the Japan Sea*, which had a very wide and rapid circulation. His *Travels in North America* were equally popular, less through their intrinsic merits, than from the violence with which they were assailed by the American press for their very partial and unfriendly view of American society. Various other works of travel followed these from Captain Hall's pen, but of inferior interest and merit. His last, which appeared in 1841 under the title of *Patchwork*, had not been long published when its author was seized with insanity, from which he was only relieved by death in 1844.

HALL, *Edward*, the author of the *Chronicle* known by his name, was born in London about the close of the fifteenth century. He was educated at Cambridge, and became a fellow of King's College there, but afterwards removed to Oxford. He then studied law at Gray's Inn, and became first a common serjeant, and finally under-sheriff of London. Before his death, which happened in 1547, he had been appointed one of the judges of the sheriff's court.

Hall's *Chronicle*, first printed by Berthelette in 1542, is now extremely rare. It is entitled, "The Union of the two Noble and Illustrate Families of Lancaster and York," and was dedicated to Henry VIII. Grafton continued the work from the point at which Hall had broken it off, and brought it down to the end of the reign of Henry VIII., and published two editions of it during his life. Another appeared in London in 1809 among the *English Chronicles*. Though the work is mentioned approvingly by Peck, Hearne, and other antiquaries, its intrinsic value does not appear to be very great.

HALL, *Joseph*, the learned and pious Bishop of Norwich, was born in 1574 at Ashby-de-la-Zouch in Leicestershire. He was educated at Emmanuel College, Cambridge, of which he afterwards became a fellow. Entering the church, he was, in 1617, appointed dean of Worcester; in the following year took part in the synod of Dort as one of the English deputies; nine years later was promoted to the see of Exeter; and in 1641 translated to that of Norwich. The latter years of Hall's life were spent in misery and gloom. His fervent piety and zeal seemed to identify him with the Puritan movement, though there was not then living a more ardent upholder of Episcopacy than he. He had given practical proof of that zeal and devotion by his able defences of the liturgy and discipline of the Church; but he had held out against the Arminianism of Laud, and thus exposed himself to the malignant and wanton attacks of that primate and his crew. "I plainly told the Archbishop of Canterbury," he said, "that rather than I would be obnoxious to those slanderous tongues of his misinformers, I would cast up my rocket. I knew I went right ways and would not endure to live under undeserved suspicions." In the January of 1642, Hall having joined the prelates who protested against the validity of all laws made during their forced absence from parliament, was committed to the Tower. It was proposed to prosecute them all for high treason, and the impeachment was actually begun, but the prosecution was finally dropped, and Hall was set at liberty, though only after finding bail for L.5000. On returning to Norwich he enjoyed comparative quiet for a short time; but in the following year his revenues were sequestrated, and even his personal property destroyed or pillaged. In 1647 he retired to Higham, near Norwich, where he rented a small farm, and passed his remaining years in the exercise of such charity and hospitality as his scanty means allowed. He died there in 1656, in the eighty-second year of his age.

Bishop Hall's works have been published in various forms, folio, quarto, and octavo. The last complete edition, that of Pratt, appeared in 1808 in 10 vols. 8vo. The great bulk of these writings is controversial, and therefore of a merely temporary interest. Some of them, however, and those probably to which the author himself attached least importance, well deserve consideration, if not perusal. Of these may be mentioned his Satires, written partly when he was a student at College, and afterwards republished under the title of *Virgidemiarum Sixe Bookes*, i. e., six books of bundles of rods. These satires are described by Warton as marked by a classical precision to which English poetry had yet rarely attained. "They are replete with animation of style and sentiment. The characters are delineated in strong and lively colouring, and their discriminations are touched with the masterly traces of genuine humour. The versification is equally energetic and elegant, and the fabric of the couplets approaches to the modern standard. His chief fault is obscurity, arising from a remote phraseology, constrained combinations, unfamiliar allusions, elliptical apostrophes, and abruptness of expression." Of Hall's prose works, the best are those on practical religion, such as his *Contemplations*, his *Art of Divine Meditation*, and his *Enochismus or Treatise on the Mode of Walking with God*. All these works exhibit originality of thought, exercised clearly and systematically on the highest truths, which are never thrown into the back ground, however, by the wonderfully fine images employed to illustrate them. His appeals are all plain, direct, and practical; and his knowledge of human nature was great, for he had studied it at a time when it took little pains to disguise its worst features. He loved to condense his shrewd observations into pithy apophthegms which alternate in strange though pleasant contrast, with trains of seer-like meditation and bursts of fervent prayer and thanksgiving. His friend Sir Henry Wotton thought to compliment him when he called him the "English Seneca," unconscious that he was associating the name of Hall with that of a man to whom he was in all respects immeasurably superior.

HALL, *Robert*, one of the most celebrated writers and preachers England has produced, was born at Arnsby, near Leicester, May 2, 1764. His father was the minister of the Baptist congregation in that place, and the author of several religious publications, one of which obtained considerable popularity. His character has been sketched by his more celebrated son, from whose testimony, as well as that of less partial witnesses, he appears to have been a man of no little ability and worth. Nor was Robert Hall less happy in his other parent—his mother being a woman of excellent sense and eminent piety. He lost her when he was but twelve years of age (1776); his father lived to rejoice in his son's dawning fame. He died in 1791.

Robert was the youngest of fourteen children. His infancy, like that of Newton, Locke, and Pascal, in whom the flame of life flickered as if it would go out almost as soon as kindled, while in the two last it but flickered all their days—was extremely sickly, and for some years there was hardly any hope of rearing him. As if to remind us how little we can anticipate the course of life, a full proportion of the great minds that have astonished and adorned the world, have come into it as if under sentence of immediately quitting it, with the worst possible promise of the great things they were destined to achieve.

Robert Hall's childhood was (as we shall presently see) unusually precocious—far more so than even that of most of the sons of genius; nor was the promise of the bright dawn, so often delusive, clouded as the day went on. It is said that he learned to talk and to read almost at the same time; his letters were assuredly learned in a strange school and from strange books, that is, in a graveyard, and from tombstones. The grave-yard was adjacent to his father's house, and thither his nurse used to carry him for "air" and "exercise." Whether a cemetery be the best place for childhood to take its "airings" in, or epitaphs the best spelling-book, may be doubted; but it was at all events a singular introduction to literature.

Even at the dame's school, where he received his first formal instructions, he betrayed his passion for books, and was often found, when school was over, in the above favourite but solemn "study"—the churchyard—engaged in solitary reading, though no longer poring over the tombstones. He pursued the same extra-official course of reading at his next school, which was kept by a Mr Simmons, at a village four miles from Arnsby. He used to procure, it appears, from his father's library, books for these play-hour readings, and, doubtless, got more from his self-prompted studies than from any of his regular lessons. But the *character* of this "select library for the young" may well surprise us, and, if the fact were not well authenticated, his choice of favourite authors would seem incredible. Jonathan Edwards' *Treatise on the Freedom of the Will*, and Butler's *Analogy*, were, it seems, among these amusing "solatia" of his leisure hours; and Dr Gregory assures us that it is "an ascertained fact," that when he was about nine or ten, he had read and re-read these works with "an intense interest." Before he was ten, another incident evinced the tendencies of his mind to literature; he had composed, it seems, many little essays, and often "invited his brother and sisters to hear him preach." Similarly, when he was once disposing in imagination (as children sometimes will) of his father's "goods and chattels" before the worthy man's death, he willingly agreed that his brother should have "the cows, sheep, and pigs," but "all the *books*" were to come to *him*.

His early promise of eloquence, conjoined with religious sensibility, seemed to point to the sacred office; and, in fact, his father indulged at a very early period some anticipations that the pulpit was his destination. At eleven he was removed to a school at Kettering, where the same brilliant talents were evinced, but not very wisely developed. His master, flattered by having such a prodigy, sometimes invited him to display his precocious powers of *oratory* before a "select audience,"—a folly which the sound judgment of Robert Hall loudly and justly condemned in after life. From this school he was removed to another of greater note at Northampton, kept by the Rev. John Ryland, a man of eccentric, but, like many others of the same family, of unusually vigorous intellect. The energy of Mr Ryland's character, and his original and impressive modes of teaching, seem to have given him a remarkable ascendancy over the minds of his pupils,—and there can be no doubt that Robert Hall's intellect was greatly and healthfully stimulated under his judicious training. Here he remained about a year and a half, and then, having decidedly expressed his predilections for the ministry, and pursued some preparatory theological studies under his father's roof, he repaired to the Baptist Academy at Bristol. This was in 1778, when only in his fifteenth year.

During his stay at Bristol he seems to have made rapid progress in all the studies which constituted the academic curriculum. His attention to the principles and practice of composition was very marked, though, as Dr Gregory observes, the few remains of his juvenile compositions exhibit "more of the tumultuary flourish of the orator than he would have approved after his twentieth year." This is a common case; for a severe taste is, even in the highest genius, of slow growth, though in Robert Hall perhaps as rapid as it ever was in any man.

His *debut* as a public speaker gave but little promise of the brilliant career which awaited him. On being appointed to deliver an address (as the students were accustomed to do in rotation) at the vestry of Broadmead Chapel, he, after a brief but fluent exordium which excited the expectations of his auditors, suddenly, but completely lost his self-possession, and covering his face in an agony of shame, exclaimed, "Oh! I have lost all my ideas." His tutor confident (as Sheridan said after his own ignominious first appearance), that it was *in* him, and determined, as was Sheridan, that it should come *out* of him, appointed him to deliver the *same* address the following week; not very judiciously, perhaps, considering the laws of association, and how apt is a sensitive mind, like a spirited horse, to *shy* and falter at the same spot. Sad to say, he again failed, and failed completely. Yet the incident was of value to him. While there was little fear lest a transient mortification like this should permanently depress a powerful mind, fully conscious of its powers,—indeed, such minds are generally stimulated rather than depressed by obstacles,—it had a salutary effect on his moral nature. In relation to the sacred office he seems at this time, as Dr Gregory observes, to have been too little sensible of its higher purposes, and too ambitious of achieving intellectual eminence; perhaps also too conscious of his powers to achieve it. Some feeling of this kind is indicated by his own words, uttered after his *second* failure,—"If *this* does not humble me, the devil must have me!" Many other young orators who have afterwards attained eminence, have encountered similar disaster in their first attempts. The singularity in Robert

Hall's case is that he had not been hardened to self-possession by his previous juvenile appearances before those "select audiences," which his injudicious schoolmaster had so early taught the young Roscius to confront.

In the autumn of 1781, after staying three years at the Academy, he went, as an exhibitioner under Dr Ward's will, to King's College, Aberdeen, where he remained till 1785. Several of the professors there were men of note, especially Gerard and Leslie, while Marischal College could boast of the prelections of Campbell and Beattie. Hall pursued his studies in the departments of classics, philosophy, and mathematics, with like distinguished success; being the first man of his year in all the classes. But the great charm of his residence at Aberdeen was the society of Macintosh, who, though a year younger, had entered college a year earlier. The friendship which ensued, and which only death dissolved, was equally beneficial to both parties. With some points of dissimilarity there were more of resemblance. The instant regards of Mackintosh, according to his own statement to Dr Gregory, were strongly attracted by Hall's ingenuous frankness of countenance, the mingled vivacity and sincerity of his manner, and the obvious signs of great intellectual vigour. He says he first became attached to Hall "because he could not help it." But daily intercourse, in which they studied together without rivalry, and incessantly disputed without anger,—a true test of genuine attachment,—cemented their first casual predilections into a lasting friendship. "After having sharpened their weapons by reading, they often repaired to the spacious sands upon the sea shore, and still more frequently to the picturesque scenery on the banks of the Don, above the old town, to discuss with eagerness the various subjects to which their attention had been directed. There was scarcely an important position in Berkeley's *Minute Philosopher*, in Butler's *Analogy*, or in Edwards *On the Will*, over which they had not thus debated with the utmost intensity. Night after night, nay, month after month for two sessions, they met only to study or to dispute, yet no unkindly feeling ensued. The process seemed rather—like blows in that of welding iron—to knit them closer together."[1] Though they both, doubtless, often fought for victory, they yet always thought at the time that it was for truth; and as Sir James strikingly said, "Never, so far as he could then judge, did either make a voluntary sacrifice of truth, or stoop to draw to and fro the *serra* λογομαχίας, as is too often the case with ordinary controvertists." From these "discussions, and from subsequent meditation upon them," Sir James declared that he had "learned more *as to principles* than from all the books he ever read."[2]

In addition to their discussions over Berkeley, Edwards, Butler, and other philosophers, they read large portions of the best Greek authors together—especially Plato. Such complete intercommunion of minds in the same studies—such mutual reflection of lights and constant collision of argument—must have been of incalculable benefit to both. By this sort of student-partnership, when, as in this case, minds are congenial, the results of reading may be more than doubled. During the last years of Hall's academic course, his friend was no longer at college, and his mind sought no "new mate." He spent the time in solitary study, and, as appears by his own confession, was much engaged in devotion and religious meditation. He took his degree of A.M. in 1785.

The six months' vacation of the two last sessions at Aberdeen had been spent in assisting Dr Evans at Broadmead Chapel, Bristol. He now formally entered on the office of assistant-preacher, and about the same time was appointed to the classical tutorship in the Bristol Academy. This office, assumed at the early age of twenty-one, he discharged with great credit to himself and benefit to his pupils for more than five years.

Of his preaching at this early period, an interesting account is given by Dr Gregory, to which we can only refer the reader. His favourite model for a short time was the original but eccentric Robinson of Cambridge, and, fascinated with his manner, he resolved, not very judiciously, to imitate it. One so original was little fitted to be an *imitator* of any body, and his good sense soon reclaimed him from his error. The account he gave to Dr Gregory of the mode in which he was cured of this folly is characteristic. "I was," he says, "too proud to *remain* an imitator. After my second trial, as I was walking home, I heard one of the congregation say to another, 'Really Mr Hall *did remind* us of Mr Robinson!' That, sir, was a knock-down-blow to my vanity; and I at once resolved that if ever I *did* acquire reputation it should be my own reputation, belong to my own character, and not be that of a *likeness*. Besides, sir, if I had not been a foolish young man, I should have seen how ridiculous it was to imitate such a preacher as Mr Robinson. He had a musical voice, and was master of all its intonations. He had wonderful self-possession, and could say *what* he pleased, *when* he pleased, and *how* he pleased; while my voice and manner were naturally bad; and, far from having self-command, I never entered the pulpit without omitting to say something that I wished to say, and saying something that I wished unsaid: and, beside all this, I ought to have known that for me *to speak slow was ruin*." "Why so?" "I wonder that you, a student of philosophy, should ask such a question. You know, sir, that force or momentum is conjointly as the body and velocity; therefore, as my voice is feeble, what is wanted in body must be made up in velocity, or there will not be, cannot be, any impression."[3]

It seems that he sometime afterwards met Robinson in London, and young as he was, opposed in a public company some of the heresies which Robinson had then embraced. This he did so successfully that the latter, provoked out of his temper and good breeding, spoke with disdain of "juvenile defenders of the faith." Hall was tempted to reply that "if *he* ever rode into the field of controversy he would at least not borrow Dr Abbadie's boots,"—a sarcasm in which there was a double sting, inasmuch as Robinson had at this time abandoned the very views which he had once "borrowed" Abbadie's arguments to defend.

An unhappy misunderstanding with his colleague in 1789, and which threatened the peace of the church at Broadmead, led to Hall's leaving Bristol. Before the close of his connection with that congregation, suspicions of heterodoxy on some points had been excited; and in reply to certain inquiries he gave a frank and explicit statement of his views. To one or two singularities of opinion, which he afterwards abandoned, he pleaded guilty. He avows he was at this time a "materialist," but declares that his sentiments did not affect his *theology*, and that he wished his materialism "to be considered a mere metaphysical speculation." It may be observed that in the same document, in which he fully avows his belief in the divinity of Christ, he makes no mention of his belief in the *personality* of the Holy Spirit—a doctrine of which at this time he was not convinced. His *materialism* he altogether abandoned in 1790;—to the ordinary Trinitarian views he did not give his unqualified adhesion till some years later (1800).

From Bristol Mr Hall went (1790) to Cambridge, to the congregation over which Robinson formerly presided. After a twelvemonth's trial of the place, he was invited to the pastorate, and accepted it. As no small portion of the congregation had been in various degrees infected with the errors of their former minister, it has been well conjectured by Dr Gregory that the very immaturity of Hall's sentiments on certain points was an advantage rather than otherwise. They listened to him when they would not have listened to a man of more strongly marked orthodoxy. As Hall gradually approximated to the sentiments generally held by his co-religionists, he led his congregation with him; and at length, by the force of his preaching, the influence of his splendid reputation, and the still better influence of his persuasive life and character, overcame all opposition to his ministry, and thoroughly weeded out the errors that had infested his flock.

[1] Gregory's *Memoir*, p. 15.

[2] *Ibid.*, p. 15.

[3] *Ibid.*, pp. 21, 22.

In 1793 he published his celebrated *Apology for the Freedom of the Press.* The account of its origin is amusing. It seems that on this occasion he was "importuned into controversy," which, in spite of his unrivalled polemical powers, he ever avoided if possible. "And so, in an evil hour," says he, "I yielded. I went home to my lodgings and began to write immediately; sat up all night; and, wonderful for me, kept up the intellectual ferment for almost a month; and then the thing was done. I revised it a little as it went through the press, but I have ever since regretted that I wrote so hastily and superficially upon some subjects brought forward, which required touching with a master hand, and exploring to their very foundations."[1] The estimate he formed of the production was, it must be confessed, sufficiently modest; for, as an exhibition of intellectual vigour, it is certainly equal to almost anything he ever produced. It may be conjectured, indeed, from the more cautious political tone in his later publications, and the far different terms in which, like his friend Sir James, he learned to speak of the French Revolution, that, had he written at a later period, he would have modified some of his statements, though he always declared his adhesion to the "essential principles" asserted. The reasons he assigns in the above extract, but, still more, his ingenuously expressed regret for the "asperities" in which he had occasionally indulged in this piece, would not permit him in his later years to consent to its republication, till the booksellers left him no alternative. An earlier tract, entitled *Christianity Consistent with the Love of Freedom*, was impudently pirated, on paper which bore the *watermark* of 1818, with a title-page which bore the year 1791! It was, as Dr Gregory says, "a very skilful imitation in paper, type, and date."

An anecdote here may be worth relating, as showing how completely at this time he had resiled from Socinianism, into which it had been once suspected he was fast lapsing. His spirited eulogium on Dr Priestley rekindled the hopes of some of that gentleman's partisans, and rendered on some occasions Mr Hall's "denial" of any of the imputed tendencies "imperative." "On one of these occasions," says Dr Gregory, "Mr Hall having in his usual terms panegyrized Dr Priestley, a gentleman who held the doctor's theological opinions, tapping Mr Hall upon the shoulder, said, 'Ah! sir, we shall have *you* among us soon I see.' Mr Hall, startled and offended by the rude tone of exultation in which this was uttered, hastily replied, '*Me* amongst *you*, sir! *Me* amongst *you!* Why, if that were the case, I should deserve to be tied to the tail of the great red dragon, and whipped round the nethermost regions to all eternity.'"[2]

In 1801 appeared one of the most eloquent and original of all his productions—the sermon on *Modern Infidelity.* A curious account of its preparation for the press is given by Dr Gregory. Like most of Hall's sermons, it was delivered almost entirely unwritten, though the matter, of course, had been profoundly meditated. The torture to which composition exposed him from the mysterious disease in his back, quite indisposed the preacher to undertake the labour of preparing the sermon for the press. It was therefore procured in fragments from his dictation as he lay on the floor (a few paragraphs or pages at a time), and passed through the press, as his biographer assures us, without the author's having seen a line of it. Of its merits it is superfluous to speak; as a luminous defence of some of the first principles of all religion, and a philosophical *exposé* of the anti-social tendencies of infidelity, it has never been surpassed. It raised Hall's reputation to the highest pitch; excited the admiration of men of all ranks and opinions; conciliated the esteem of those who had been offended with the *Apology;* crowded his chapel with throngs of university students; and, perhaps a still better proof of its success, exposed him to the rabid attacks of atheism and its champions.

Two other discourses of surpassing excellence appeared in the course of the great struggle with France. One was entitled *Reflections on War*, preached on occasion of the "general thanksgiving," at the transient peace of Amiens (1802). This, as Dr Gregory surmises, was the only sermon Hall ever delivered *memoriter*, and the embarrassment he felt in some passages was sufficient to prevent him from ever repeating the attempt. The other was delivered on the renewal of the war (1803), and was entitled *Sentiments proper to the present crisis.* In spite of one or two rhetorical flights, scarcely admissible in a Christian pulpit, it is deservedly considered one of the most extraordinary effusions of his eloquence.

During the latter years of his residence at Cambridge this powerful and brilliant mind was more than once transiently eclipsed. These accesses of mental disease were doubtless attributable to many causes; partly to solitude, partly to excessive study, partly to the severe and harassing suffering in his back and the sleepless nights which it occasioned, partly to a severe disappointment, but principally, no doubt, to that which exacerbated all other causes of mischief—the exquisitely strung and sensitive mind which is too often, as Dryden long ago observed,

> . . . . "to madness near allied,
> And thin partitions do their bounds divide."

Just before his first attack (Nov. 1804) his severe sufferings from his old complaint induced his medical advisers to recommend his living a few miles from Cambridge, and using horse exercise. Equestrian exercise would seem a questionable remedy, considering the local symptoms of his mysterious disease, though country air might doubtless be beneficial. But whatever advantage this might secure was more than counterbalanced, it is to be feared, by the solitude to which his secluded residence doomed him, and which probably much contributed to his mental attack. The retreat chosen for him was at Shelford, four miles from Cambridge. There he was engaged in solitary study and meditation during the whole day, and often deep into the night. The first melancholy attack took place in Nov. 1804.

To the delight of his congregation, who had proved, by their provident care of him, their attachment to his ministry, he was able to resume his public functions in April 1805. As it was feared that the associations of Shelford might prove prejudicial, he was recommended to change his residence, and, most injudiciously as it seems to us, he was again advised to reside in a remote village. He took a house at Foulmire, nine miles from Cambridge. Solitude once more proved his bane, and another attack soon supervened. After a year spent under judicious medical care at Bristol, he recovered sufficiently to engage in occasional village preaching, and to apply moderately to study. But it was thought prudent that he should quit Cambridge altogether, and he accordingly sent in his resignation.

---

[1] Gregory's *Memoir*, p. 33.

[2] *Ibid.*, p. 35.

Mr Hall spent about fifteen years at Cambridge. Of his residence there—his studies, his modes of preparation for the pulpit, his social habits—an interesting account will be found in Dr Gregory's *Memoir*, to which only a reference can here be made. His biographer naturally dwells with partial minuteness on this period of Hall's history, as that in which he became intimate with him, and enjoyed unrestricted daily intercourse. It was that period also in which Mr Hall achieved his great public reputation, and produced his most brilliant, if not his most useful, publications.

Leicester was the next scene of Hall's labours, whither he removed in the year 1806, and where he resided nearly twenty years, longer by some years than at any other place. In the limits of this brief article there is no space for details, nor is it necessary. He lived as retired as his reputation would allow him to be. If fame came, it came unsought; if the world intruded upon him, as it often did, and often inconveniently, he gave it a courteous welcome, but was still better pleased when it left him to his studies and his flock. But much as he loved privacy, privacy for him was no longer solitude; in 1808, after a somewhat singular courtship, he married, and, as it turned out, most happily. This event largely contributed to his welfare; and it is observable that no symptoms of mental disease afterwards appeared. In relation to what he himself would consider the *great* purpose of his life,—the successful prosecution of his ministry,—the years spent at Leicester were the best of his life. However obscure might seem his lot, it was yet most happy; for he was eminently useful, and universally beloved. His chapel was twice enlarged to accommodate the increasing crowds who thronged to hear him. Occupying a central spot in the kingdom, he was frequently importuned to preach, on public occasions, in all directions of the compass; and, so far as his incessant and painful maladies permitted, he complied with such requests ungrudgingly. From time to time, and quite as frequently as the same physical infirmities allowed, he also gave the public the benefit of his pen. Besides several reviews, tracts, and other pieces, he published, during his residence at Leicester, some of his most celebrated sermons; two of them—on the *Discouragements and Supports of the Christian Minister*, and on the lamented *Death of the Princess Charlotte*—are among the most striking efforts of his eloquence. He here also published the largest, and in some respects most valuable of his writings—those on the *Terms of Communion*. These treatises are equally distinguished by acuteness of logic and catholicity of sentiment. It has been sometimes lamented that he should not have given his consummate logical powers a more ample theme. But, in fact, his genius has made the theme ampler than it seems. Not only have these pieces exerted a wide influence in liberalizing the opinions and practice of his own denomination, but they abound in reasonings and sentiments of practical application to every church in Christendom, and cannot be read by any thoughtful Christian without making him feel something of that noble expansion of soul which animated their author; without making him sigh for the day when "every middle wall of partition," which jealous bigotry has interposed to the inter-communion of those who reciprocally acknowledge each other to be Christians, may be "broken down."

On Dr Ryland's death (1825), Mr Hall was invited to Bristol, and, after a severe struggle, consented. It is scarcely a figure to say that he tore himself away from his congregation at Leicester. On the last occasion of celebrating the Lord's Supper, he sat down, overcome with his emotions, and, covering his face with his hands, "wept aloud." To see the "strong man thus bowed," dissolved the people also in tears;—and so they parted; his flock, as the Ephesian elders from Paul, "sorrowing most of all for the words that he spake, that they should see his face no more."

Mr Hall was in his sixty-second year when he removed to Bristol, and it was his last change; thus terminating his labours where he began them. He was fast approaching the close of his career. The mysterious and intractable malady which had so long tormented him, which had rendered his days and nights so "wearisome," became more urgent, and doses of opium almost fabulous produced little effect. The indirect effects of his complaint,—forbidding exercise, inducing plethora, and impeding the circulation,—produced that diseased condition of the heart which was the immediate cause of his death. The close of his life was a scene of frightful tortures, the sum of which, added to the almost constant pain in which his life was passed, must have been tantamount to many martyrdoms. The pages in Dr Gregory's "Life" which depict his last sufferings, and the triumph of patience over them, form some of the most sorrowful, and yet also some of the brightest, in the records of Christian biography. Deep were the clouds which gathered round his sunset, but they were all penetrated and transfigured by the glory of the descending luminary; and even he who doubts whether Christianity be true, can surely hardly read the closing scenes of this great and good man's life without feeling, that since humanity is thus subject to suffering, it is much to have such consolations. His death took place, February 21, 1831. After detailing the appearances presented by the *post-mortem* examination, the eminent physician, Dr Prichard, adds,—"*Probably no man ever went through more physical suffering than Mr Hall*;[1] he was a fine example of the triumph of the higher powers of mind, exalted by religion, over the infirmities of the body. His loss will long be felt in this place, not only by persons of his own communion, but by all that have any esteem for what is truly great and good."[2]

The mind of Robert Hall was of that select order which are equally distinguished by power and symmetry; where each single faculty is of imposing dimensions, yet none out of proportion to the rest. His intellect was eminently acute and comprehensive; his imagination prompt, vivid, and affluent. This latter faculty, indeed, was not so exuberant (as Foster justly remarks) as that of a Burke or a Jeremy Taylor; nor could it have been so, without marring the harmony just mentioned. His reasoning was close as that of almost any controvertist of any age, but expressed in all the charms of a most chaste and polished style;—severe logic clothed in the most tasteful rhetoric. His talents for the successful prosecution of abstract science—especially metaphysical and ethical—were of a very high order; but they were conjoined with strong practical sense, keen powers of observation, and a vivid sensibility. His memory was tenacious, and his aptitudes for the acquisition of knowledge, generally, far beyond the ordinary measure; but in him, as in all very vigorous minds, diversified Knowledge was but the material and aliment of original thought, and was subordinated to that Wisdom which insists that it shall be the handmaid, not the mistress of intellect. His sense of the beautiful and the ludicrous seemed nearly equally vivid; and graceful imagery and pointed wit animated alike his writings and his conversation. His style is the very impress of all this amplitude and variety of endowments. It is masculine and compact, for a robust logic and strong sense form the basis of it; energetic and vivacious, for it is animated by imagination and sensibility; polished and elegant, for taste, exquisite, sometimes even to a morbid fastidiousness, presided over it.

---

[1] No wonder; for, to say nothing of the agonies of the closing scene, it was found that the "right kidney was *entirely filled* with a large rough-pointed calculus;" and this Dr Prichard justly concludes to have been the cause of the dreadful torture that had harassed Mr Hall through life.

[2] Gregory's *Memoir*, p. 134.

On the whole, minds of greater power in several given directions, or of more absolute originality in some one, may be readily pointed out; some too more strongly characterized either by rugged strength or imaginative exuberance; but seldom indeed has a mind appeared so variously dowered with all the choicest gifts of strength and grace in happy unison.

It has been well said of his style by a critic in the *Quarterly Review*, that it is "constructed after no model; it is more massive than Addison's, more easy and unconstrained than Johnson's, more sober than Burke's." This is, in fact, one of its surpassing excellencies; it is eminently beautiful, but for that reason has no predominant features; it is the just image of the happy conjunction and equilibrium of the author's powers;—music in which no excess in any of the parts mars the harmony.

If his more elaborate productions have a fault at all, it is the result of that very sensitiveness of taste to which reference has been made. In polishing to an extreme of fastidious elegance, he has perhaps here and there pared away a little of the energy of his style. For this reason it has even been conjectured that some of his strictly extemporaneous effusions—extemporaneous as to the *language*—to which he gave utterance in the all but preternatural dilation of mind, which sometimes characterized his eloquence in its prime, transcended in force and beauty his most deliberate compositions, produced as these always were amidst bodily sufferings little favourable to the free action of his faculties. In truth, his extemporaneous command of all the resources of language (equally seen in the pulpit and in conversation) was one of his most extraordinary endowments, and perhaps, to the degree in which he possessed it, almost unique. Some may have been as copious in their diction, others as precise; but he conjoined both excellencies in equal measure, and added to them, what is more rare, an astonishing command of *construction;* so that he could throw the rapid and voluble words, which seemed to come at will, into the most apt and elegant collocations.

This singular gift of extemporaneous speech put the copestone on all his other excellencies as an orator. The general structure of his mind, his robust reasoning faculties, his vigorous though ever ministering imagination, his keen sensibility, and his vehement passions, pointed in the same direction, and fitted him to be a great public speaker. Such he would have become under any circumstances; but it was his rare gift of extemporaneous language which enabled him to combine the immense advantages of unwritten composition with a freedom from all its usual defects; to clothe, not extemporaneous thoughts indeed,—on which no man should reckon, though after careful preparation such thoughts may come unbidden,—but carefully meditated matter, in all the graces of the most eloquent language. His usual mode of preparation for the pulpit is thus described by Dr Gregory:—"The grand divisions of thought—the heads of a sermon for example—he would trace out with the most prominent lines of demarcation; and these, for some years, supplied all the hints that he needed in the pulpit, except on extraordinary occasions. To these grand divisions he referred, and upon them suspended all the subordinate trains of thought. The latter, again, appear to have been of two classes, altogether distinct; outline trains of thought, and trains into which much of the detail was interwoven. In the outline train the whole plan was carried out and completed as to the argument; in that of detail the illustrations, images, and subordinate proofs were selected and classified; and in those instances where the force of an argument or the probable success of a general application would mainly depend upon the language, even that was selected and appropriated, sometimes to the precise collocation of the words. Of some sermons, no portions whatever were wrought out thus minutely; the language employed in preaching being that which spontaneously occurred at the time: of others, this minute attention was paid to the verbal structure of nearly half: of a *few*, the entire train of preparation, almost from the beginning to the end, extended to the very sentences. Yet the marked peculiarity consisted in this, that the process, even when thus directed to minutiæ in his more elaborate efforts, did not require the use of the pen, at least at the time to which these remarks principally apply."[1]

So perfect was the form in which he could give expression to a train of thought, that (as already intimated) it may even be surmised that his spoken style often surpassed, in all the essential excellencies of eloquence, that of the most admired and elaborate of his published discourses; the former having all the advantages of a more idiomatic diction and more colloquial construction, yet without the sacrifice of the precision and elegance which distinguish the latter. His frequent paroxysms of pain must at all events have tended continually to distract his mind, and diminish the glow of feeling when in the act of composition; and hence the extreme reluctance with which he undertook the task. On the other hand, under the excitement of public speaking, the consciousness of painful sensations was less vivid, and sometimes vanished, as appears from one of his own curious but most sad confessions. He tells us that he did not know that he was ever perfectly free from the consciousness of distressing sensations in his back except now and then *for a few minutes in the pulpit.*

The same felicities of extemporaneous speech which marked his pulpit efforts were observable in private. His conversation possessed a vivacity, affluence, and elegance very rarely equalled. His repartees were particularly happy, and, as has been well remarked, strongly remind one of the manner of Johnson. Some of the pungent sayings, full of mingled wit and wisdom, which Dr Gregory has recorded, make one regret that some Boswell was not always at hand to preserve those brilliant but evanescent effusions of his genius.

Many have lamented that he did so little (compared with some other men) by his pen. In truth, however, considering his constant sufferings and the dreadful toil which composition imposed upon him, his six octavos entitle him to be considered even a *voluminous* writer.

Though, like most other men of powerful minds, he was fonder of thinking than reading, his acquisitions were various, and, in several branches of study, profound. It may be added that his ardour in the pursuit of knowledge followed him to the last, of which Dr Gregory gives us a singular example. He says that he found him one morning, in the closing years of his life, lying on the floor with an Italian grammar and dictionary, deep in the study of that language. To this he had been stimulated by an article in the *Edinburgh Review*, in which an elaborate parallel had been instituted between the genius of Dante and that of Milton. With this critique he had been, he said, much delighted, and wished to judge for himself of the accuracy of the views propounded. Among the many triumphs achieved by Mr Macaulay's genius, it may be doubted whether any was ever more signal than that nearly his first "Essay" induced a mind like that of Robert Hall to study a new language at the age of threescore, just to verify the justice of the criticisms.

It has been justly remarked by Mr Foster, in his admirable critique on Robert Hall as a "preacher" (well worthy of universal perusal), that his eloquence in later years lost somewhat of the fire which characterized the oratory of his youth and manhood. But what was lost in this respect was gained in tenderness and pathos, in elevation of Christian sentiment and depth of Christian feeling.

---

[1] Gregory's *Memoir*, pp. 57, 58.

It is the crowning glory of Robert Hall that all his great powers were consecrated to the noblest purposes; subordinated to objects better worth living for than intellectual power or intellectual fame. His sacred ambition was for the formation, in himself and others, of the Christian character. To moral self-culture he sought, as all ought to do, but so few really do, to consecrate every endowment of his intellect. Of the possession of high powers he could not but be conscious; and of the temptations they involved he was also profoundly sensible. His life shows us that he had learned how to make them keep their place. Naturally impetuous, impatient, choleric, he sedulously watched over these infirmities in temper, and became remarkable for humility and simplicity; full of ambition, he submitted to cast down "every proud imagination;" in his youth fiery and pugnacious, he learned in his later years to hate controversy, and exercised in an eminent degree that charity towards all good men of all parties, which made him say in one of his sermons, "He who is good enough for Christ is good enough for me." In his manners he was as unsophisticated as a child, and in his conduct full of generosity and benevolence. His patience and fortitude were eminently displayed in the uncomplaining endurance of those frightful sufferings which made his life a perpetual martyrdom; while his faith and humility were evinced no less in his admission that none of those pangs could have been spared. It has been well said by a writer in the *Quarterly Review*, "It is impossible to read the works of this extraordinary man without perceiving that his passions in his youth were turbulent in the extreme—that the energies of his mind were then scarcely under his own control—that years of reflection and dear-bought experience were wanting to him, above all men, in order to tame his spirit—that, like Milton's lion, he was a long time before he could struggle out of earth. 'I presume,' says he, in one of his letters, 'the Lord sees I require more hammering and hewing than almost any other stone that was ever selected for his spiritual building, and that is the secret of his dealing with me.'" In a word, he exhibited the traits of the genuine Christian—his character shining with a more lustrous light as he advanced in years, "growing brighter and brighter to the perfect day."

The character to which he chiefly aspired himself, he was equally anxious to aid in forming in his fellow men, and to this consecrated his genius as an object well worthy of it. Hence his contentment with a lot far more obscure than he could easily have attained in any department of secular life; and hence, with Paul, he accounted it his chief glory to be a "Christian Minister." (H. R.)

HALLE, a city of Prussian Saxony, government of Merseburg, on the Saale, 20 miles N.W. of Leipzig, with which, as well as with Magdeburg and Eisenach, it is connected by railways. Halle is surrounded by old walls, and irregularly built, with little to attract the eye of the stranger. It is chiefly celebrated for its university, which once ranked among the foremost in Germany. It was founded in 1694, and in 1815 was united with that of Wittemberg. It still continues to maintain a high character, particularly as a school of Protestant theology. It has faculties of theology, law, medicine, and philosophy; and in session 1853–54 had 71 professors and teachers, and 650 students. Connected with it are a number of scientific institutions, as a botanic garden, observatory, museum, library of 90,000 vols., theological and philological seminaries, chemical laboratory, anatomical theatre, cabinet of minerals, &c. Three hospitals connected with the medical school afford the students ample opportunities of seeing practice. There are a number of other educational institutions in Halle, the chief of which is the *Frankesche Stiftung*, founded by A. W. Franke in 1698. It comprises schools for the education of children of both sexes, in various stations of life, though chiefly of the poorer classes, to the number of 2220; a laboratory, where medicines are prepared and distributed; and a Bible press, which has sent forth some millions of copies of the Scriptures at a cheap rate. In the inner court of the building a fine bronze statue of the founder by Rauch was erected in 1829. Its cost was defrayed by public subscription, to which the King of Prussia largely contributed. St Mary's Church is a Gothic building of the sixteenth century; St Maurice's is a building of the twelfth, and was restored in 1840. In the market-place is a singular structure, 250 feet high, called the Red Tower. The old Castle of Moritzberg, formerly the palace of the Archbishops of Magdeburg, was mostly destroyed in the Thirty Years' War, and the only remaining wing is now used as a Calvinistic church. Outside the walls is an elegant monument to those Germans that fell at the battle of Leipzig in 1813. The salt springs in the neighbourhood of the town produce annually about 280,000 cwt. of salt. The labourers employed in them are a peculiar and distinct race called Halloren, said to be descendants of the Wends, who anciently peopled this country. Halle, besides several suburbs, comprises the towns of Glaucha and Neumarkt, each of which has its own magistrates. Pop. (1849) 33,848.

HALLEIN, a town of Upper Austria, circle of Salzburg, on the river Salzach, near the foot of the Dürrenberg, and 9 miles S. of Salzburg. It has very extensive salt works, producing annually about 400,000 cwt. of salt. Pop. 5000.

HALLELUJAH or Halleluiah. See Alleluia.

HALLER, Albert Von, one of the most illustrious physiologists of the 18th century, was born of a patrician family at Berne, October 16, 1708. He was a very precocious child, one of the few precocious children whose after life did not belie the promise of their early childhood. He was sickly and feeble, and disabled by the rickets from taking part in boyish sports. At the age of four he used to read and expound the Scriptures to his father's servants. At eight he had redacted some 2000 biographies from the Dictionaries of Bayle and Moreri. At nine he wrote in Greek the exercises that his school comrades were writing in Latin, and before his 15th year he had constructed vocabularies in Greek and Hebrew, and had written tragedies, comedies, and even an epic of 4000 lines in the manner of Virgil. When some of these youthful productions were in danger of perishing in a fire, the author, to the great danger of his life, rushed in and saved them. Afterwards, however, when time had matured his taste, he made a bonfire of them of his own accord. Choosing medicine as a profession, he began his studies at Tübingen under Camerarius and Duvernoy, but in a short time he exchanged Tübingen for Leyden, where Boerhaave and Albinus were then at the zenith of their fame. In 1727 he graduated, having chosen for the subject of his thesis Coschwitz's discovery of a salivary duct, which he proved to be nothing more than a blood-vessel. After graduation he visited London, where he formed the acquaintance of Sir Hans Sloane, Cheselden, Pringle, and other leading physicians and observers. From London he removed to Paris, where he continued his studies under Ledran and Winslow, after which he quitted Paris for Basle, where he perfected himself in mathematics under John Bernouilli. After an absence of five years he returned to his birth-place, where he was appointed keeper of the public library, and, soon after, physician to the infirmary. At the very moment when he was contributing elaborate Latin papers to a scientific journal at Nuremberg, he showed the versatility of his powers in a volume of poems which he published at this time. These various works made him known to George II. of England, who had just organized the university of Göttingen. Haller was offered the second medical chair, which comprised botany, anatomy, and surgery, and after some hesitation he accepted it. The town of Göttingen was at this time in a state of the most ruinous disrepair; and the carriage of the new professor, as he was driving through the streets, was upset, and his wife was killed. He was devotedly attached to her and bewailed her death in an ode, the finest he ever wrote. All thoughts of his personal afflictions, however, were soon dissipated by the work which he chalked out for himself. The quantity of work that he passed through his hands during the seventeen years that he held his chair in Göttingen is amazing, even though its quality be left out of account. He organized all sorts of schools, made botanical excursions into the Harz, edited and wrote prefaces for countless works, contributed largely to many scientific transactions, took part in numberless discussions, and collected materials to be digested and published during his retirement. The honours he received from the various sovereigns of Europe were numerous and flattering, but he steadily resisted all the efforts made by England, Prussia, Austria, France, and Holland, to entice him away from his native country. In 1753 he retired to Berne, where he was invested with numerous offices, lucrative but easy. The remainder of his life was spent in scientific inquiries, the active fulfilment of his official duties, and the exercise of every charity. He died in October 1777.

Haller's works comprise in all upwards of two hundred treatises, bearing upon nearly every department of medical science,—and establishing his claim to the title of the father of modern physiology. He was, in truth, the first who was bold enough to discard the old chemical and mechanical, as well as the old metaphysical explanations of the laws which govern the animal economy. Basing his whole system on a thorough knowledge of anatomy, and the structure of each individual organ as found in the dead body, he strove to evolve the powers that showed themselves in action in the living frame. These powers—and they are the dominant idea in Haller's physiological works—he limited to two, *irritability* and *sensibility*. The former of these has its seat in the muscular fibre, and differs wholly from the latter, which resides in the nervous system. The differences in the manifestations of these two powers he illustrated by detaching a muscle from the frame and stimulating it. He found that when pricked or otherwise stimulated, such a muscle showed its irritability by contracting, though it was not sensible; whereas a nerve when stimulated was found to remain perfectly unmoved, though the muscles with which it communicated were thrown into violent action. From this he inferred that irritability does not lie in the nerves, which cannot be supposed able to communicate a power they do not possess. The germ of this idea Haller seems to have taken from Gorter and Glisson, but in his hands this irritability became a new law, to which he referred almost all the animal functions; and the chief error he seems to have fallen into regarding it is, in having distinguished it too absolutely from the nervous power on which it always depends. The controversies to which his works gave rise contributed powerfully to advance the science of physiology, to which many valuable additions were soon made, among others, the important fact, which Haller either overlooked or denied, but which was proved beyond a doubt by Bichat, that every tissue has a life peculiar to itself (*vie propre*), and that a special stimulus is required to show the action of each particular organ. Haller had evolved this idea as early as 1739, and had announced it in the *Primæ Lineæ Physiologiæ*, published in 1747; but it was not till the appearance of his *Elementa Physiologiæ Corporis Humani*, 1757–1766, that he made known his doctrine in all its entirety. This work, the greatest on its subject that saw the light in the 18th century, is nearly as remarkable for the elegance and beauty of its style as for the value and novelty of the ideas it contains. A posthumous supplement to this work appeared in 1782. From 1771 till his death, Haller was engaged in publishing his *Bibliothecæ Anatomiæ, Chirurgiæ, Botanicæ, Medicinæ Practicæ, et Historiæ Naturalis*, which make up in all 10 quarto volumes, but were only completed after Haller's death. His *Opera Minora*, comprising the most valuable of his contributions to the various scientific periodicals, were published at intervals between 1762 and 1768. His *Icones Anatomicæ*, which he himself reckoned among his best works, occupy 46 plates, and present valuable drawings of many of the organs, more especially of the arteries. (Zimmerman's *Life of Haller;* Art. by Cuvier in the *Biog. Univers.; Eloges of Haller*, by Tscharner, Baldinger, Heyne, Condorcet, and Vicq. d' Azyr.) See also the art. Physiology.

HALLEY, Edmund. See art. Astronomy, vol. iii., p. 804, and the fourth Preliminary Dissertation, prefixed to this work.

HALLOWELL, a village in Kennebec county, state of Maine, North America. It stands on an acclivity on the right bank of the Kennebec river, and on the Kennebec and Portland Railroad, 58 miles N. by E. of Portland. It carries on a considerable trade, and vessels drawing 9 feet of water can come up to the wharves. A fine kind of granite is found in the vicinity, and largely exported. Pop. (1850) of township, 4769.

HALLOWMAS, the Feast of All Souls; or the time about All Souls' and All Saints' Day, viz., the 1st and 2d of November, and thence to Candlemas, or 2d of February.

HALMOTE, or Halimote, the Saxon name for what is now called a *court-baron*, the word implying a meeting of the tenants of the same hall or manor. The name is still retained at Luston and other places in Herefordshire.

HALMSTAD, a maritime laen of Sweden, bounded on the W. by the Kattegat, and on the other sides by the laens of Göteborg, Wenersborg, Jonköping, Wexiö, and Christianstad. Area, 1900 square miles. The coast is in some parts sandy, in others bold and rocky, and is much indented, forming several considerable bays. The eastern part is mountainous, but the western is generally level and sandy. The soil is poor, stony, and ill cultivated, so that about one-third of the corn required for food has to be imported. The fisheries and cattle-rearing chiefly engage the attention of the inhabitants. Pop. (1850) 51,382. The capital is of the same name, and stands at the mouth of the Nissa, 76 miles S.S.E. of Gothenburg. It has some trade in deals, pitch, and tar, an important salmon fishery, and about 1900 inhabitants.

HALO. See Corona; Chromatics, section ii.; Meteorology.

HALSTEAD, a market-town in the county of Essex, on an acclivity rising from the river Colne, 46 miles E.N.E. of London. The town, though irregularly built, has a neat appearance, and the streets are generally wide and clean. The parish church, a fine Gothic building in the perpendicular style, has been recently almost wholly rebuilt. The Church of the Holy Trinity is also a handsome building, in the early English style, erected in 1844. Halstead possesses a grammar and other schools, mechanics' institute, savings bank, market-house, and several charities. Market-day, Friday. Manufactures of silk and velvet and straw-plaiting are chiefly carried on. Pop. (1851) 5658.

HALTERES (ἁλτήρες), in the gymnastic exercises of the Greeks and Romans, were certain masses of lead, iron, or stone, held in the hands in leaping, to give impetus to the body; or swung to and fro in much the same manner as our dumbbells. Galen (*De Tuend. Valetud.*, lib. i., v., and vi.) recommends this kind of exercise for purifying the humours of the body.

HALTWHISTLE, a market-town of England, county of

Northumberland, on the left bank of the South Tyne, 34 miles W. of Newcastle, on the Newcastle and Carlisle Railway. It is pleasantly situated, but is irregularly built and poor. The chief manufacture is baize. Market-day, Thursday. Pop. (1851) 1420.

HALYS, now the Kizil Irmak, or Red River, the largest stream in Asia Minor, rises in Pontus, not far from Nicopolis. Traversing in a S.W. direction the south of Pontus and the north of Cappadocia, it reaches the Mons Argœus. It there turns to the north, traverses Galatia in a N.W. course as far as the town of Gangra on the frontier of Paphlagonia. Passing Gangra, the river flows in a N.E. direction into the Euxine Sea, separating Galatia and Pontus from Paphlagonia. Its mouth is about 50 miles distant from Sinope. As the Halys was by far the largest river in Asia Minor, a common division of that country was Asia cis-Halyn and Asia trans-Halyn. The whole length of the river is about 500 miles, but it is not well adapted for regular navigation by ships of any considerable size. In summer, indeed, it is so shallow that it may be crossed in almost any part of its course by wading. When swollen by the rains it brings down large quantities of alluvial soil, which discolours the waters of the Black Sea for 6 or 7 miles from the embouchure. A considerable delta has in this way been formed at the mouth of the river.

HALYWERCFOLK, in our old writers, the Saxon term for persons who enjoyed land by the pious service of repairing some church or defending a sepulchre. It was likewise applied to certain persons in the diocese of Durham who held their lands by the tenure of defending the corpse of St Cuthbert.

HAM. 1. The youngest son of Noah. Having provoked the wrath of his father by an act of indecency towards him, the latter cursed him and his descendants to be slaves to his brothers and their descendants. To judge, however, from the narrative, Noah directed his curse only against Canaan (the fourth son of Ham) and his race, thus excluding from it the descendants of Ham's three other sons, Cush, Mizraim, and Phut. How that curse was accomplished is taught by the history of the Jews, by whom the Canaanites were subsequently exterminated. The general opinion is, that all the Southern nations derive their origin from Ham (to which the Hebrew root חם, *hot*, not unlike the Greek Αἰθίοπες, lends some force). *Cush* is supposed to have been the progenitor of the nations of East and South Asia, more especially of South Arabia, and also of Ethiopia; *Mizraim*, of the African nations, including the Philistines and some other tribes which Greek fable and tradition connect with Egypt; *Phut*, likewise of some African nations; and *Canaan*, of the inhabitants of Palestine and Phœnicia. On the Arabian traditions concerning Ham, see D'Herbelot, *Dictionnaire Universel*.

2. A poetical name for the land of Egypt. In the Egyptian language XHMI, or KHME, signifies *black*. Plutarch also calls Egypt *Chemia*: τὴν Αἴγυπτον ἐν τοῖς μάλιστα μελάγγειον οὖσαν, ὥσπερ τὸ μέλαν τοῦ ὀφθαλμοῦ, Χημίαν καλοῦσιν.

In Gen. xiv. 5 occurs a country or place called *Ham*, belonging to the *Zuzim*, but its geographical situation is unknown.

HAM, a Saxon word signifying a place of dwelling, a house, a village, or town; as in the word *hamlet*, and in such names as Waltham, Buckingham, Nottingham, &c. It is the same as the Scottish *hame* for home.

HAM, a town of France, department of Somme, in a marshy plain 15 miles S.S.E. of Peronne. It is chiefly celebrated for its strong fortress, used as a state prison. In 1830 Prince Polignac and the other ministers of Charles X. were incarcerated here; and more recently Louis Napoleon, the present Emperor of France. Pop. of town, about 2000.

HAM, the thigh of a beast, particularly of a hog; but more particularly applied to the thigh of that animal when cured. The process of curing is performed either by steeping in brine, or by rubbing in bay-salt. It is usual to rub a little powdered saltpetre over the hams before salting; and they are often flavoured with brown sugar or treacle. Wet salting requires about three weeks, and dry salting a week longer. Hams are also made of mutton and beef. The final operation is that of smoking.

HAMADAN, or Amadan. See Ecbatana.

HAMADRYADES (formed of ἅμα, *together*, and δρυάς, *dryad*, from δρῦς, *oak*), in *Antiquity*, certain deities believed by the ancients to preside over woods and forests, and to be inclosed under the bark of oaks. The Hamadryades were supposed to live and die with the trees to which they were attached, as is observed by Servius on Virgil (*Eclog.* x., ver. 62), after Mnesimachus, the scholiast of Apollonius, who mentions other traditions relating to the same subject. The poets, however, frequently confound the Hamadryades with the dryads, naiads, and rural nymphs in general. See Dryads.

HAMAH, a city of Syria, on both sides of the Orontes, which is here crossed by four bridges, 110 miles N. by E. of Damascus. It is the Hamath of Scripture, and the Epiphaneia of the Greeks. The kingdom of Hamath lay between Zobah on the E. and Rehob on the W.; and, like Dan, is used to denote the northern boundary of the Holy Land, as in 1 Kings viii. 65, "from the entering in of Hamath unto the river of Egypt." The entering in, or entrance in, of Hamath, was a mountain pass forming its approach from the south, and was the passage from the northern extremity of the land of Israel into Syria. Amos (vi. 2) styles it Hamath the Great. Toi was king of Hamath at the time when David conquered the Syrians of Zobah. In the time of Hezekiah the town along with its territory was conquered by the Assyrians. Abulfeda, the Arabian geographer, who was prince of Hamath in the fourteenth century, states that this "is reckoned one of the most pleasant towns of Syria. The Orontes flows round the greater part of the city on the east and north. It boasts a lofty and well-built citadel. Within the town are many dams and water-machines, by means of which the water is led off by canals to irrigate the gardens and supply private houses. It is remarked of this city and of Schiazar, that they abound more in water-machines than any other cities in Syria." This description is in a great measure still correct. It is surrounded by walls and otherwise well defended; but, as in most Syrian towns, the streets are narrow, irregular, and dirty. Being on a great caravan route between Asia and Africa, it has an active commerce. It has manufactures of silk and cotton fabrics, gold and silver thread, &c. Pop. about 44,000.

HAMAXOBII, or Hamaxobitæ (ἅμαξα, *a carriage* or *chariot*, and βιος, *life*), an ancient people of Sarmatia Europæa, who inhabited the southern part of Muscovy, and lived in tents made of leather and fixed on carriages, so as to be ready for travelling at all times.

HAMBATO, or Ambato, a town of South America, state of Ecuador, department of Quito, 75 miles S. of the town of that name, and at the N.E. foot of mountain Chimborazo, 8860 feet above the level of the sea. Pop. about 10,000.

HAMBURG, a sovereign state of the Germanic Confederation, consisting of, 1. The city of Hamburg, and a small adjacent territory between Holstein and Hanover; 2. Of several islands in the river Elbe; 3. Of several scattered portions of land in Holstein and Lauenberg; and 4. Of the bailiwick of Ritzebuttel and the island of Neuwerk, on the coast of the North Sea, between the Elbe and the Weser, altogether, about 150 square English miles, with a population of 211,000 inhabitants.

The city of Hamburg is situated on the north bank of a branch of the river Elbe, in N. Lat. 53. 34., E. Long. 9. 47., about 50 miles from the North Sea, and nearly an equal distance from the Gulf of Lübeck, in the East Sea. A few miles above the town the Elbe divides into two main branches, called the North Elbe and the South Elbe, and these, again subdividing, form a number of fertile islands, occupying a breadth of about five miles in front of the town. Between these islands and the city the North Elbe has a breadth of from 1000 to 1200 feet, and the windings of its banks and sub-branches form several havens that constitute the harbour; but there are no docks. The city, however, is intersected by the river Alster, and a number of canals, that carry the merchandize from the ships to the very warehouses of the merchants. The River Alster, from Holstein, forms two lakes, or large basins, on the north-east side of the town, one outside, and the other within the walls. The latter called the Binnen Alster, is an ornamental piece of water, which, in German eyes, gives Hamburg an appearance of beauty few cities in Europe can boast of. The city consists of five distinct portions, two of which, called the Altstadt and the Neustadt, are within the walls, divided from each other by the Alster; a third, called the Hamburger-Berg, or the suburb of St Paul—the most pleasantly situate part of the town—extends northward along the river to the Danish frontier, where it is divided from Altona by a ditch eight feet wide; the fourth portion, called the suburb of St George, lies in the north-east quarter; and the fifth, a new suburb, called the Hammerbrook, has been laid out on a marshy track in the east or south-east quarter. The city proper was formerly surrounded by strong fortifications, consisting of numerous bastions, curtains, and outworks; but, since the peace of 1814, these have been all demolished, and the ground they occupied has been laid out in walks and gardens. Their outline, however, is still marked by a wet ditch, 120 feet wide, with 10 to 12 feet of water. Besides these walks there are, within the the town, two promenades, the one called the *Jungfernstieg* (young ladies' walk), along the south side, and the other, called the New Jungfernstieg, along the west side, of the Binnen Alster basin.

Until the fire in 1842 the Altstadt of Hamburg consisted of narrow, crooked, and dirty streets, lined with large, lofty, and gloomy houses, inhabited even by the better classes, while the lower classes were densely crowded into courts, closes, and cellars. At that time, however, about a third part of the city was destroyed, and advantage has been taken of the calamity to introduce various improvements in the new buildings, to widen the streets, to establish water-works, form sewers, and fill up ditches. The public buildings are not worth notice as objects of architectural or artistic interest. The council-house and the bank, both destroyed at the time of the fire, have been rebuilt in better style, and the church of St Nicholas, also destroyed, is now being restored, from a design in the Gothic style by an English architect. The finest building is the church of St Michael, erected between 1762 and 1786, which has a tower of 460 feet in height, affording an extensive view over the adjoining country, and along the Elbe, almost as far as the sea. The exchange, likewise, is a fine building in the Adolphe Platz. The charitable institutions are numerous, and some of them on a magnificent scale. The orphan-house provides for the maintenance and education of 600 children, and the apprenticing of them to useful trades. The great hospital in the suburb of St George is capable of containing about 5000 sick, and the yearly cost of supporting it is about L.17,000. The schools are well conducted; there is a gymnasium or high school, and a Johanneum, an establishment of the same kind, a sort of college, both scientific and practical. There are French and German theatres, and every means is taken to satisfy the prevailing taste for music and dancing.

The manufacturing industry of Hamburg is very considerable. The principal branches consist of sugar-refining, spinning-mills, hat-making, linen, silk, and velvet weaving, calico-printing, snuff and tobacco manufacture, whalebone-cutting, and gold and silver smithery; but it is as the commercial entrepôt and shipping port of Northern Germany that Hamburg is most distinguished. From its position on the tideway of a river navigable for more than 500 miles from the sea, it enjoys a prodigious internal trade. Communicating by water with a great part of Prussia, and with the whole of Saxony and Bohemia, it supplies these countries with all the colonial and other foreign productions that they require, and exports in return their raw and manufactured produce. With the East Sea it is connected by canals; and now, it is connected also with Kiel, Wiemar, and Rostock, by railways through Holstein and Mecklenburg, and by other railways with Berlin, Magdeburg, Brunswick, and Hanover, and other parts of Germany. The value of the merchandise imported from all parts of the world, in 1853, amounted to L.32,828,590; and in 1854, to L.39,247,322. The value of the exports for the same two years was respectively L.31,186,268, and L.36,463,665. Hamburg is consequently a great centre of money transactions, which are managed by a large number of private bankers. The trade is conducted entirely by silver, deposited by its owners in the Bank of Hamburg, and transferred by means of checks. This bank possesses no capital, and therefore neither discounts bills nor makes advances on any sort of securities. It is purely a place of deposit; and its expenses are paid by a charge on the transfers. The amount of bullion in its vaults is reckoned at about L.4,000,000. The number of seagoing vessels that arrived and cleared out in 1854, with their tonnage and crews, are stated in the following table:—

From and To	Arrived.			Departed.		
	No. of Ships.	Burden in tons.	Crews.	No. of Ships.	Burden in tons.	Crews.
Europe.....	4427	742,155	34,878	4326	702,723	33,660
America...	416	139,083	5,037	473	152,862	5,466
Asia	39	19,290	627	17	6,528	254
Africa	13	3,276	142	13	3,822	152
Australia ..	1	300	10	50	25,079	759
Totals...	4896	904,104	40,694	4879	891,014	40,291

The number of ships belonging to Hamburg at the end of 1854 was 456, with a burden of 159,867 tons.

Hamburg has now regular communication by steam-ships with London, Hull, Grimsby, Newcastle, Leith, West Hartlepool, Rotterdam, Amsterdam, Gothenburg, and Bergen.

The government of Hamburg was formerly very aristocratic; but the great commotion of 1848 produced a change of the constitution. The government is now vested in a senate of fifteen members, of whom seven must be well acquainted with law and finance, and six with commerce. There is also a council of burgesses, consisting of 192 members, who appoint a civic committee of twenty members, to assist the senate on urgent and important business. The senate names from its own body, for its president, a first and a second burgomaster, who serve for a year, and who, if re-elected, cannot remain in office more than two years consecutively. The manner of election to these councils is very complicated, and far removed from popular suffrage and control. The public revenues are derived from various sources, and the budget for 1855 stood thus:

Receipts.		Expenditure.	
From State property ...	L.29,015	Ordinary	L.420,161
... Indirect taxes	262,659	Extraordinary	15,800
... Direct taxes	60,115		
... Sundry receipts ...	50,124		L.435,961
... Special receipts ...	3,867	Excess of expenditure	30,181
Total	L.405,780		L.405,780

The amount of the public debt was L.4,828,477. The military force is very small; and the Hamburg contingent to the Federal army is only 1947 men.

The city and suburbs contained, in 1853, 161,390 inhabitants, of whom the greater part were Lutherans, not more than a tenth part being Catholics, Calvinists, Jews, Mennonites, and of other sects. They are divided into three classes. The first consists of the *Handelstand* or Traffickers, subdivided into *Kaufleute*, or mercantile people, and *Kramer*, or retail dealers. The second class consists of the learned, such as ministers of religion, schoolmasters, lawyers, and medical practitioners. The third class consists of artizans and day labourers, the paid officers of the state, soldiers, servants, strangers, and Jews. Any one may be a merchant who chooses, but the Kramers form a corporation or guild. The officers of the state are not allowed to carry on trade; but those who are invested with honorary offices may continue their business. Of the lawyers it is not required that they should have gone through a regular course of study; but all who become members of the courts or the senate must be doctors of law. Strangers cannot possess any real property, or follow any civil profession; and the Jews, though there are nearly 10,000 of them resident in the city, cannot properly become citizens.

Early in the ninth century a castle was erected by Charlemagne on the spot where Hamburg now stands, and the place soon became of importance. In the reign of Otto IV. (1215) it was constituted a free city of the empire, and, in the year 1241, a commercial treaty between Hamburg and Lubeck formed the foundation of the powerful Hanseatic League. Shipping and trade formed always the principal objects of attention with the citizens, and they soon made their city one of the principal trading towns in the north. In 1536 the Hamburgers joined the league of Schmalkald, and the Reformed religion became fully established. Their independence was often threatened by the kings of Denmark, till, in 1768, all differences were settled, and, for a considerable sum of money, their imperial privileges fully acknowledged. During the period of French intrusion, Hamburg suffered most severely. Its trade was ruined by the English blockade, and the citizens were impoverished by forced loans to their foreign rulers. In 1810 Hamburg was annexed to the French Empire; and in 1813–14 it was in possession of a French army, under Marshal Davoust, who withstood a siege from the Allies till 31st May 1814, when it was freed from its oppressors. In 1815 it was acknowledged as one of the free cities and sovereign states of the German Confederation. Since that time its trade has increased enormously, and its population has more than doubled.

The principal place of note in the territory of Hamburg is Cuxhaven, a town of about 1000 inhabitants on the seacoast, outside of the mouth of the Elbe. It is noted for its lighthouse, and harbour. South-east of the city is a low alluvial tract, called the *Vierländer*, consisting, as the name implies, of four distinct portions, divided by rivers. They are said to rival the Egyptian Delta in fertility, and are inhabited by people of very primitive manners and habits, who marry only among themselves, and regard strangers with jealousy. They are said, however, to be very wealthy, finding in the city a ready market for all their produce.

HAMEL, Jean Baptiste du. See Duhamel.

HAMELN, a town of Hanover, principality of Calenberg, on the river Weser, at its confluence with the Hamel, 25 miles S.W. of Hanover. It is surrounded by old walls scarcely defensible, and was formerly protected by Fort George on the opposite side of the river; but this fort was destroyed by the French in 1806. The Weser is here crossed by an iron suspension bridge 500 feet in length, supported by a pier erected on an island in the middle of the river. Hameln is interesting as containing many wooden houses of the old German style. Being the capital of a cognominal bailiwick, it is the seat of several courts and public offices; and from the river being here navigable, it carries on a considerable trade. The navigation was improved by the construction of a large sluice here in 1734, by George II. A salmon-fishery and various branches of manufacture are carried on. Pop. 6500.

HAMESECKEN, or Hamesucken. Burglary, or nocturnal housebreaking, was, by the ancient English law, called *Hamesecken*, as it is in Scotland to this day.

HAMILCAR, the name of a number of persons who distinguished themselves in the history of Carthage. By far the most eminent of the name was Hamilcar Barca, the father of Hannibal. The details of his exploits are given under Carthage.

HAMILTON, a municipal and parliamentary borough and market-town of Scotland, county of Lanark, about a mile from the junction of the Avon with the Clyde, and 10 miles S.W. of Glasgow. The town originated in the fifteenth century, under the protecting influence of the lords of Hamilton, who constituted a place called the Orchard, between this point and the Clyde, the principal messuage of the barony, and which is still the chief seat of the Hamilton family. In 1451, a collegiate church was founded in the vicinity; but in 1732, the new church was built.

The town of Hamilton occupies a rising ground, commanding fine views of a rich and highly picturesque country, and consists of several streets of well-built houses, somewhat irregularly dispersed. The proprietors, alive to the value of their grounds for feuing purposes, have published various competing plans for villas. This, together with its ready access with Glasgow by railway (half-an-hour's ride), and the amenity of the locality, are rapidly converting Hamilton into a suburb of Glasgow. The staples of trade are silks and cambrics. Many of the females are engaged in tambour or sewed muslin work. Both coal and ironstone are found in the parish, and are largely wrought. It is governed by a provost, two bailies, and twelve councillors; and unites with Airdrie, Linlithgow, Falkirk, and Lanark, in returning a member to parliament. Dr Cullen, Professor Millar of Glasgow, Dr Matthew Baillie, and his sister Joanna Baillie, were natives of Hamilton. Pop. (1851) 9630; registered electors 300. Market-day, Friday.

Immediately east of the town is *Hamilton Palace*, the seat of the Duke of Hamilton, premier peer of Scotland. The pleasure-grounds around the mansion comprise nearly 1500 acres. The present palace was commenced in 1822, and consists of a large elegant building in the style of the Temple of Jupiter Stator at Rome. The interior is highly decorated; and contains one of the most valuable collections of paintings in Scotland. Within the policies, on the summit of a precipitous rock, 200 feet in height, the foot of which is washed by the Avon, stand the ruins of Cadzow Castle, the original seat of the Hamilton family. It was conferred on the chief of that family immediately after the battle of Bannockburn, having been previously a royal residence for at least two centuries. In the park attached to the castle are still preserved some of the old Scotch breed of wild cattle; they are milk-white in colour, excepting their muzzles, horns, and hoofs, which are black.

Hamilton, a town of Upper Canada, beautifully situated on Burlington Bay, at the western extremity of Lake Ontario. It is well laid out, and contains some fine public buildings, among which are two market-houses, a customhouse, post-office, and theatre. Being the capital of the district of Gore, it is the seat of the court and public offices for the district. Hamilton was founded in 1813, and incorporated in 1833. In 1844 it had 5669 inhabitants, and in 1852, 14,112, while in 1854 they were estimated at about 20,000. See Canada, vol. vi., pp. 135–44–52, &c.

HAMILTON, Anthony, *Count*, author of the *Memoirs* *of Count Gramont*, was a cadet of the noble Scottish family of that name, and was born in Ireland about 1646. He was educated in France, but after the Restoration passed over to London, where he met the Chevalier, afterwards Count de Gramont. This nobleman, temporarily banished from the French court, fell in love with Hamilton's sister, and engaged to marry her. As soon as his term of exile had expired he set out for Paris, neglecting to fulfil his engagement. Anthony and a younger brother of the bride took horse, and overtaking the fugitive at Dover, asked him if he had forgotten nothing in London. "Pardon, gentlemen," said the Count, "I forgot to marry your sister." He returned, and the ceremony was performed. Hamilton made frequent voyages to France to see his sister and her husband; and on one of these occasions was chosen by Louis XIV. to figure in Quinault's ballet of the *Triomphe de l'Amour*. Exiled with James II., who had warmly befriended him on account of his attachment to the Catholic religion, he spent the remainder of his days at St Germains, where he wrote his delightful works, and where he died in 1720, at the age of about seventy-four.

Of Hamilton's works, the best and the best remembered is his *Mémoires de Gramont*. It is indeed the cleverest book of its class in existence. Though no one who reads it can fail to see its frivolity, it is impossible to lay it aside without reading on to the end. The pictures of the court of Charles II. which it contains, are like the best pieces of Boucher. Expressing almost nothing, they yet possess charms and attractions denied to the far more ambitious efforts of greater minds. Though the grossest indelicacy is often hid by a mere veil of gauze, and is thus doubly dangerous, especially to the young reader, there is yet a grace, a truth to nature, and a gaiety in the work that make it one of the most pleasant, as it certainly is one of the most valuable records of the dissolute court of the Restoration. Hamilton's other works, once much in vogue, are now forgotten. There have been many editions of the *Memoirs* both in France and England. One of the rarest is that printed by Horace Walpole at the Strawberry Hill press, of which only 100 copies were thrown off; better still is the London edition of 1792; but best of all is that of 1811, with sixty-three portraits, and many notes and illustrations, some of which are said to have been furnished by Sir W. Scott. One of the best editions is that of Paris in 4 vols. 8vo, 1812, or 5 vols. in 18mo, 1813.

Hamilton, *Elizabeth*, the author of some admirable novels and educational works, was born at Belfast in Ireland, of parents of Scottish extraction. Of her personal history little is known. She seems to have been a governess in the family of a Scottish nobleman, and to have written to the eldest of her pupils, her *Letters on the formation of the Religious and Moral Principle*. She died after a painful illness at Harrowgate, July 23, 1816. After her death a very well written notice of her literary life and labours appeared in the *Monthly Magazine* for Sept. 1816, which was attributed on good grounds to Miss Edgeworth.

Of all Miss Hamilton's works the best known, though not the most valuable, is her novelette, entitled the *Cottagers of Glenburnie*. In this work she describes with graphic force and effect the manners of the lower grades of the Scottish rural population of her day. The filth, self-complacency, laziness, and contentedness of the loutish sluggards that figure in that story are so humorously, so truly, and withal so kindly described, that the book soon gained and still enjoys a wide popularity, and has been really useful in stimulating a great social reformation. Her other leading works are the following, which we give in chronological order:—*Letters of a Hindoo Rajah*, 1796; *Modern Philosophers*, 1800, a kind of satire on the admirers of the French Revolution, and the dangerous absurdities of their doctrines when carried out to their legitimate conclusions; *Letters on the Elementary Principles of Education*, 1801–2; *Life of Agrippina, wife of Germanicus*, 1804; *Exercises in Religious Knowledge*, 1809; *Popular Essays*, 1813. The most valuable though not the best known of her works, is her *Letters on Education*, in which she applies to education, and brings within the compass of general comprehension the metaphysics of the question, which before her time had seemed reserved for philosophers only. In the words of Miss Edgeworth, she "shows how the doctrine of the association of ideas may be applied in early education to the formation of the habits, of temper, and to the principles of taste and morals; she has considered how all that metaphysicians know of secretion, abstraction, &c., can be applied to the cultivation of the judgment and the imaginations of children. No matter how little is actually ascertained on these subjects, she has done much in wakening the attention of parents, and of mothers especially, to future inquiry. She has done much by directing their inquiries rightly; much by exciting them to reflect upon their own minds, and to observe what passes in the minds of their children."

Hamilton, *Gavin*, a distinguished Scottish painter, was born at Lanark in the course of the first half of the eighteenth century. At an early age he was sent to Rome, where he studied art under Massuchi. The highest qualities of a great painter—invention, purity, and correctness of style, and the secret of colour, he undoubtedly lacked. No small part of his merit lies in his choice of subject, to which he was helped by his fine taste and his deep knowledge of classical literature. His best pieces are designs from the *Iliad*, such as "Achilles beside the dead body of Patroclus;" "Andromache bewailing the death of Hector;" "Helen and Paris." Hamilton, however, has rendered greater services to art by his discoveries of precious fragments of ancient monuments than by his direct contributions to it. The latter part of his life was devoted to researches of this kind, which he prosecuted in various parts of the Roman States, but especially at Civita Vecchia, Velletri, Ostia, and above all at Hadrian's Villa, at Tivoli. The statues, busts, and bas-reliefs found by him form the most interesting portion of the Museo Clementino after the treasures of the Belvidere. Many collections in England, Germany, and Russia, owe their chief ornaments to his labours. To one of the best of these—the Townley Gallery—Hamilton contributed a large number of valuable marbles, a list of which is given in the *Townley Gallery*, published by the Society for the Diffusion of Useful Knowledge. Fuseli, giving expression to the feelings of all who knew Hamilton, declares that however great his talents may have been, they were far surpassed by the generosity, benevolence, and humanity of his character. The only work known to have proceeded from his pen is his *Schola Italica Picturæ*, Rome, 1773, in which he traces the progress of the different styles of the Italian school from Da Vinci down to the Caracci.

Hamilton, *Robert*, an eminent Scottish writer on political economy and finance, was born at Edinburgh in 1743. After an excellent education he entered a bank, where he passed the first years of his youth as a clerk, and thus acquired a practical knowledge of financial affairs, which he afterwards turned to good account. In 1760, however, he changed his views, and, resolving to devote himself to teaching, was made rector of the Perth Academy, and ten years later was promoted to the chair of natural philosophy in Marischal College, Aberdeen. In 1780 he exchanged this chair for the more congenial professorship of mathematics in the same university. For some years before his death in 1829, Hamilton had retired from the active business of his chair, and quitted his privacy only at rare intervals to take part in important affairs concerning the college.

Hamilton published a number of minor pieces, but it was not till the appearance of his *Essay on the National Debt* in 1813 that he attracted especial attention as a political economist. That work, published under the title of an *Inquiry concerning the Rise and Progress, the Redemption and Present State, and the Management of the National Debt of Great Britain*, was written with a view to expose the inadequacy of the sinking-fund system, which had been received as an axiom in financial science ever since the days of Pitt. In course of time Hamilton's views, regarded at first with disfavour, came to be known and adopted in other countries of Europe than Great Britain. His other works, such as his *Introduction to Merchandise*, his essay on *War and Peace*, exhibit marks of strong common sense, and a vigorous understanding; but as they discuss their subjects solely with reference to the actual state of things and without allusion to the future, their interest has long since died away.

Hamilton, *Sir William*, a diplomatist and patron of the fine arts, was a native of Scotland, where he was born in 1730. On the threshold of youth he was condemned (to use his own words) to make his way in the world with an illustrious name and a thousand pounds. He took the first step with characteristic caution and boldness, and made his career in life smooth and easy by marrying in 1755 a lady of large fortune, with the additional recommendations of youth, birth, and beauty. Nine years after this Sir William was made ambassador at Naples, and retained that office till 1800. After the death of his first wife he married (in 1791) the beautiful but abandoned Emma Harte, whose name as Lady Hamilton is so painfully associated with that of Nelson. (See Nelson.) Sir William returned to England in the first year of the present century, and died there in very reduced circumstances in 1803.

It is not as a diplomatist but as a lover of art that Sir William Hamilton has a claim to posthumous renown. His great work, the *Campi Phlegræi*, is a noble monument of mingled art and science. It consists of a series of coloured engravings executed with admirable taste and spirit, showing the volcanic action of Vesuvius, and some of the most remarkable eruptions that occurred in the course of his sojourn at Naples. His collection of vases was one of the best private collections of that day. Engravings and descriptions of the most valuable pieces are given in the famous *Antiquités Etrusques, Grecques, et Romaines, tirées du Càbinet de M. Hamilton*, edited by d'Hancarville. Many of these are now in the Townley Gallery in the British Museum. The interest that Sir William took in art and antiquity is attested by his contributions to the *Philosophical Transactions*, his *Observations on Vesuvius, Mount Etna*, &c., and his zeal in furthering and superintending the excavations made at Herculaneum and Pompeii. He even contributed liberally out of his private fortune the means of forming the museum at Portici, and of properly caring for and profiting by the MSS. and other valuable articles rescued from the buried cities. The Neapolitan government looked upon his enthusiasm with coldness if not positive suspicion.

Hamilton, *William, of Bangour*, one of the minor poets of Scotland, was born in Ayrshire in 1704. He is not so much remarkable for original or strong powers of mind as for having been one of the first of native-born Scotchmen who wrote English verse with elegance, correctness, and good taste. One of his ballads, however, that entitled

Busk ye, busk ye, my bonny, bonny bride,

is in its own vein little if at all inferior to the best of the old ballads. Hamilton joined the standard of the young Chevalier in the '45, and, after Culloden, was obliged to fly to the continent. On being pardoned he returned to Scotland, but delicate health drove him once more to France, where he died in 1754. There have been numerous editions of his poems.

HAMLET (from Sax. *ham*, domus), a little village or small cluster of houses in the country. This word, says Stow, originally meant the seat of a freeholder, comprehending the mansion-house and adjacent buildings.

HAMLET, a prince celebrated in the annals of Denmark, whose name has been rendered familiar by forming the subject of one of the noblest tragedies of Shakspeare. Adjoining a royal palace, which stands about half a mile from that of Kronberg, in Elsinore, is a garden, called Hamlet's Garden, and, according to tradition, is the very spot where the murder of his father was perpetrated. The house is of modern date, and situated at the foot of a sandy ridge near the sea. The garden occupies the side of the hill, and is laid out in terraces. Elsinore is the scene of Shakspeare's Hamlet; and the original history from which our poet derived the principal incidents of his play is founded upon facts, but so deeply buried in remote antiquity that it is difficult to discriminate truth from fable. Saxo Grammaticus, who flourished in the twelfth century, is the earliest historian of Denmark who relates the adventures of Hamlet. His account is extracted, and much altered, by Belleforest, a French author, an English translation of whose romance was published under the title of the *Historye of Hamblet;* and from this translation Shakspeare formed the groundwork of his play, though with many alterations and additions.

HAMM, the capital of a cognominal circle in the Prussian province of Westphalia and government of Arnsberg, on the Lippe, at its confluence with the Ahse, 22 miles N.N.W. of Arnsberg. It is inclosed by walls, but the ditches that formerly surrounded it have been filled up and converted into promenades. Hamm was formerly a member of the Hanseatic League: it has a famous gymnasium, bleach works, manufactures of linen and woollen fabrics, leather, &c., and an active trade in hams. It is situated at the intersection of the Cologne-Minden Railway by that between Munster and Paderborn. Pop. (1849) 6005.

HAMME, a town of Belgium, province of East Flanders, 18 miles E.N.E. of Ghent, on the right bank of the Durme, near its confluence with the Schelde. It has breweries and oil-mills; and some manufactures of linen, soap, cordage, &c. It also carries on a considerable trade with the surrounding country. Pop. (1851) including commune, 9684.

HAMMER, a tool used by mechanics, which consists of an iron head fixed crosswise upon a handle. The hammers used by blacksmiths are of several kinds; as, the hand-hammer, which may be wielded with one hand at the anvil; the up-hand sledge, used with both hands, and seldom lifted above the head; the about-sledge, which is the largest of all, and held by both hands at the furthest end of the handle, and, being swung at arm's-length over the head, is made to fall upon the work with a heavy blow. There is also the *riveting hammer*, which is the smallest of all. Carpenters and other artizans have likewise hammers suited to their several purposes.

The name of *steam-hammer* has been given to various powerful machines worked by steam, for dealing heavy blows with rapidity and precision. The steam-hammer of Mr Nasmyth, the introducer of this machine, is particularly deserving of mention, as greatly economizing time and labour, and for its successful employment in ironmaking, the forging of anchors, pile-driving, &c. See Iron-Making.

HAMMERFAST, a town of Norway. See Lapland.

HAMMERSMITH, a town and parish in the county of Middlesex, 4 miles W. by S. of London, near the N. bank of the Thames, which is here crossed by an elegant suspension bridge. The parish church is a plain brick building with a low tower, erected in 1631. A new district church was erected in 1820. There are also chapels for Wesleyan Methodists, Baptists, Quakers, and Roman Catholics; two Roman Catholic convents; almshouses; and national and other schools. The parish is studded with numerous elegant residences, and the neighbouring grounds are chiefly occupied by nurseries and market-gardens, which furnish the metropolis with some of the choicest flowers and vegetables. Pop. of parish (1851), 17,760.

HAMMOCK, or Hamac (Span. *hamáca*—a word of Indian origin), a kind of hanging bed which is suspended between trees or posts, or to hooks. The true Indian hammock is a long narrow net made of strong cord, and terminated at each end by small ropes for suspending it. The hammock used on board ship consists of a piece of stout canvas, about six feet long and three broad, gathered at the ends and suspended by cords.

HAMMOND, Henry, a learned divine of the Church of England, was born at Chertsey in 1605. He was educated at Eton, and graduating at Oxford became a fellow of Magdalene College. Upon taking orders he became rector of Penshurst in Kent, and in 1643 archdeacon of Chichester. When the civil war broke out he hastened to join the king at Oxford, was made canon of Christ Church, and public orator in 1645. Three years later he was driven from the university by the parliamentary visitors, and confined for some time. After regaining his liberty he retired to Westwood, in Worcestershire, the seat of Sir John Pakington, where he spent the remainder of his days, dying at the very moment when the restored head of the Stuart family had fixed upon him for preferment to the see of Worcester.

Hammond's works, published in 4 vols. fol., 1674-84, consist, for the most part, of controversial sermons and tracts. The best of them are his *Practical Catechism*, his *Paraphrase and Annotations on the New Testament*, and an incomplete work of a similar nature on the Old Testament. Though these, with others of Hammond's works, have long since lost any value they may at one time have had, their author possessed many qualities entitling him to be remembered long after his works are forgotten. He was an excellent preacher. Charles I., whose taste on æsthetic questions was indisputable, pronounced him the most natural orator he had ever heard. His range of reading was very extensive, and comprised modern as well as ancient literature and philosophy. His charities and kindnesses to the poor were unbounded. Antony-à-Wood says that he became known as the "most zealous promoter of almsgiving that lived in England since the change of religion," and that, consequently, he "had the disposal of great charities reposed in his hand." With all this wealth, however, his habits were self-denying and abstemious, and he often gave away in charity luxuries which might have been of much service to his own feeble health. His industry was astonishing. "No burden was more heavy," he used to say, "or temptation more dangerous, than to have time lie on one's hand." In 1739 a collection of Hammond's Letters was published by Peck.

Hammond, *James*, the son of Anthony Hammond, the "silver-tongued Hammond," as he was named by Bolingbroke, from the persuasive sweetness of his forensic eloquence, was born in 1710. He was educated at Westminster school, and became equerry to the Prince of Wales. He entered parliament as member for Truro in 1741, and died the following year. While still a very young man, he published his *Love Elegies*, correct and tasteful pastorals indeed, but cold and vapid. Dr Johnson was not too severe when he said, "these elegies have neither passion, nature, nor manners." The heroine, whom the author calls Delia, was a Miss Dashwood, whose scorn of the poet's love first drove him mad, and finally sent him to his grave at the early age of thirty-two. The lady, we are told, survived him for seven and thirty years without finding any one else either to marry or fall in love with her. Dr Johnson observes that the character which Hammond bequeathed her was not likely to attract courtship.

HAMPDEN, John, the celebrated leader of the Long Parliament, was descended from an ancient and honourable family of Buckinghamshire. His father was the proprietor of the large family estates, and died while his son was an infant. His mother was the daughter of Sir Henry Cromwell of Hinchinbrook, and the aunt of the great Oliver, who was thus John Hampden's cousin-german. After passing through the courses of the grammar-school of Thame and Magdalene College, Oxford, he began the study of the law at the Inner Temple. In 1619 he married and began to reside permanently on his estates, leading the same sort of life as was led by most English squires of the day. When the king found it necessary to summon a parliament, Hampden was returned first by the borough of Grampound, then thrice consecutively by Wendover, and finally entered the Long Parliament as one of the members for the county of Bucks. His history from this time till he fell mortally wounded in the skirmish with Prince Rupert upon Chalgrove Field, June 18, 1643, is the history of England. (See Great Britain.) As Hampden comes before posterity as a party-man and the leader of a party, it is extremely difficult to form an estimate of his character such as will reconcile the various accounts of him that we possess. His partizans excite our pity when they set him up as the greatest man of his age, and as a man in whom were centred and surpassed the high and valuable qualities of Cromwell, Vane, Manchester, Hale, and Sidney. Equally absurd is the conduct of those who deny that he possessed great sagacity, great powers of debate, great courage in war, and great ability as an administrator and man of practice. He was not a man of genius, as Cromwell was; but he had great talents, and a mental constitution as refined as powerful. His *personnel* seems to have been a highly interesting one. He was the only leading man among the Parliamentarians in whom the Royalist wits could find nothing to assail. There is no act of his life in which he can be charged with anything like meanness or want of soul. His patriotism was at once a principle and a sentiment, and his noble self-devotion and heroic end prove that it was as strongly approved by his judgment as accordant with his sympathies. After hearing that his wounds were fatal, he quietly continued the despatch of some important public business; which done he calmly awaited his end. His last prayer was a prayer, not for himself only, but for his country which even in the agonies of death occupied his thoughts:—"Lord Jesus, receive my soul. O Lord, save my country. O Lord, be merciful to ——." His death was that of a Christian as well as a hero. (See Carlyle's *Cromwell;* Nugent's *Memorials of Hampden;* Hume, *Hist. Engl.;* Clarendon, *Hist. Rebel.;* Macaulay, *Hist. Engl.;* and *Essay on Hampden* reprinted from *Edinburgh Review.*)

HAMPSHIRE, Hants, or county of Southampton (anciently *Hamtechare*), a maritime county of England on the shores of the English Channel, bounded on the N. by Berkshire, E. by the counties of Surrey and Sussex, S. by the English Channel, and W. by Wiltshire and Dorsetshire. It is of an irregular quadrilateral form, and is about 46 miles in extreme length from N. to S., by 41 in extreme breadth. This is exclusive of the Isle of Wight, which is comprised in the county, and is about 23 miles long from E. to W., by 14 broad from N. to S. The entire area is 1,070,216 acres, or 1672 square miles. Hampshire, in its general aspect, presents a beautiful variety of gently rising hills and fruitful valleys, adorned with numerous seats and pleasant villages, and interspersed with extensive woodland. In comparison with many other counties it has but little waste land, but at the western extremity, bordering on Dorsetshire, a small portion of sandy heath is scarcely productive of anything but pasture for sheep. A considerable tract, extending from Winchester to the northern extremity of the county, is down-land, principally used for sheep-pasture, but when brought under the plough is very fertile in barley, turnips, clover, and sainfoin. This county contains a great extent of woodland. The New Forest, so well known from its association with William the Conqueror, contains about 92,000 acres, but within its boundary a large portion of the land is highly cultivated and very fertile. The abundance of trees of large dimensions, the open glades between, and the variety of foliage and underwood, render the scenery of the district highly delightful. The oaks, many of which are of some hundred years' growth, are the characteristic feature of the forest. They do not grow to a great height, but swell to large dimensions in the trunk, and shoot out strong crooked branches, which give them a very picturesque appearance, and add to their value as naval timber, being well adapted for use as knees in ships of the largest size. The beech trees also grow to a very great size, and contribute to the beauty as well as the profits of the forest.

The other principal forests are those of Alice Holt and Woolmer, situated within a short distance of each other, near the eastern border of the county, and extending over about 15,500 acres; of which nearly one-half belong to the crown, and afford excellent oak timber. Bere Forest, also, in the south-east, a few miles to the north-east of the Portsdown Hills, and about five miles from Portsmouth, contains about 16,000 acres, but its timber has been much neglected. In these forests there is abundance of deer belonging to the crown, some of which are annually killed, and distributed (according to ancient prescription) among the various officers of the government and the royal household. The greater part of the county is inclosed, and even the down-lands are so in a great measure.

The principal rivers of Hampshire are the Itchen, the Avon, the Boldre, the Tees, and the Anton. The Itchen rises near Alresford, flows by Kingsworthy, Winchester, and Twyford, and falls into the Southampton Water. This river has been navigable from Winchester to Southampton as early as the Conquest. The Avon has its source in Wiltshire, enters the county near Breamore, passes by Fordingbridge and Ringwood, and after being joined by the Stour, a small Dorsetshire river, which only passes through about six miles of Hampshire, empties itself into Christchurch Bay. The Boldre takes its rise in the New Forest, and, after collecting the waters of several brooks during its course through the forest, it falls into Lymington Creek. The Tees or Test rises in the neighbourhood of Whitchurch, and, after receiving the Anton and numerous small brooks, passes by Stockbridge and Romsey, and forms the head of the Southampton Water. The other rivers are the Exe, Hamble, and a few small tributaries of the Thames, which water the northern portions of the county.

The canals of the county are but two—Basingstoke and Andover. The Basingstoke Canal was begun in 1778, to communicate between that town and London. It is 37 miles in length, and terminates near Guildford in the River Wey. It passes through a tunnel, nearly three-quarters of a mile in length, under Grewell Hill, near Odiham. This canal was not completed till 1794, when it had cost L.100,000; and the tolls are not yet sufficient to pay the interest. The Andover Canal was begun in 1789, at that town. Its termination is at Redbridge, and it is useful to convey coals and other heavy commodities to the centre of the county. It is continued by a branch to Salisbury.

Several railways traverse the county. There is communication with London by means of the South-Western Railway, which enters Hampshire at Farnborough, passing by Winchester, and from thence to Southampton, a branch diverging from Bishopstoke to Gosport, and again to Portsmouth *via* the South Coast Railway, by a branch from Foreham. The South Coast Railway also affords to the south-eastern portion of the county ready access to London, through Brighton. This line enters the county at West Boarne, passes by Havant and a few other unimportant places, into Portsmouth. A branch from Reading and the Great Western Railway joins the South-Western at Basingstoke, and the Guildford and Reigate branch of the South Coast Railway communicates with Alton. A line called the Direct Portsmouth Railway, commenced in August 1853, is in course of construction. The projectors of this line intend to form a junction with the South Coast Railway at Havant, whence it is to pass along the eastern border of the county to Godalming, and thence by the Woking Junction and South-Western Railway to London. This line, when completed, will shorten the distance between London and Portsmouth by 22 miles. Southampton communicates with Dorchester by the Dorchester Railway, which passes by Ringwood, and with Salisbury by a branch line passing through Romsey. At present Plymouth and other parts of the south-west of England can only be reached by the Great Western Railway, a most tedious and circuitous route; but other lines have been projected, which will make a material alteration in this respect. The towns of Southampton and Portsmouth are in communication with London by means of the electric telegraph, which is also in operation between Southampton and Dorchester.

The soil is very various, but in almost every part it rests on a calcareous subsoil. The uplands are generally appropriated to breeding sheep, and hence the culture of turnips has been much extended. After the turnips are eaten off the land, barley is usually sown, and with it clover, or other artificial grass-seeds. To the clover succeeds sometimes wheat or oats, and, when the land is somewhat heavier in texture, occasionally beans; but in few parts of England are the rotations of crops more diversified. The average produce of corn on these high lands is not more than 16 bushels of wheat, 22 of barley, and 24 of oats, to the acre. The ploughing is almost universally performed by horses, which are of a very excellent breed. On much of the stiffer lands four of these strong horses are thought necessary; but on lighter lands, and with a single-wheeled plough, sometimes two or three are used, and very rarely are harnessed abreast of each other. On the higher lands the hay for winter consumption is generally made from sainfoin, a plant which peculiarly flourishes when the subsoil is calcareous. When it is sown great care is taken to extirpate all weeds, and every other description of grasses, and thus the crop will usually continue for ten years to be fit for mowing; and on some soils it has been found to last even twenty years, and yield abundant crops of hay. There is no part of England in which this valuable grass is so well or so extensively cultivated.

The corn lands on the lower levels of the county are much more productive; but on those districts they have no occasion for sainfoin, and scarcely for clover, as their rich water meadows supply them with a sufficiency of hay. Some of these meadows are perhaps the most valuable of any lands in this island, and are managed with great skill and attention. Where a rapid stream of water can be passed over them during the whole winter, it seldom becomes frozen; and the grasses grow during the cold weather, so as to be fit for pasture at an early period in the spring, before any traces of vegetation appear in the surrounding fields. This young grass is a provision for the sheep when no other green food is to be found, and supplies them to the beginning of May, when it is allowed to grow, and in six or eight weeks it is fit to be mowed, and yields an abundant supply of hay. There is much of this valuable description of land in the fertile valley that extends from Overton to Redbridge by Stockbridge.

In the eastern part of the county, bordering on Surrey, there are extensive hop plantations, the produce of which is equal in flavour to those in the adjoining villages of that county near Farnham.

A parliamentary report on the agricultural statistics of this county gives the number of acres of arable land, in October 1853, at 603,219½. Of these 96,228¼ were in wheat, 62,380¾ barley, 57,075¼ oats, 1907½ rye, 14,096¾ peas and beans, 13,868½ tares and vetches, 2801¼ potatoes, 83,847 turnips or rape, 388½ carrots, 1515¾ mangel-wurzel and beet-root, 355 cabbages, 100,114½ clover, lucerne, &c., 123,519½ meadow and pasture, 73¼ flax, 1711¼ hops, 4260 other crops, 39,076½ fallow. The woods or plantations covered an area of 105,839½ acres, and commons or wastes occupied 89,630¼. There were 24,076 horses, 19,350 milch cows, 13,148 other cattle, 489,227 sheep and lambs, and 61,860 swine.

The original breed of Hampshire sheep was white-faced, with horns; but these have been so often crossed with other kinds, that few of an unmixed breed are left. Most of the flocks now are of the Southdown kind; they are found to be more profitable, both on account of the superior quality of their wool, and the tendency to fatten with a less quantity of food than any others. The cows are not much attended to, and are not generally of the best kind. The introduction of the Welsh breed has made some improvement, but there is room for much more.

The breeding and fattening of pigs has long been a most important part of Hampshire husbandry. The bacon from them is the principal animal food of the rural inhabitants. In the vicinity of the forests the pigs are fed on acorns and beech-mast; and those so fattened are considered the best, either for pickled pork, or for bacon. The average weight of these animals when deemed fit for slaughter is about 440 or 450 lbs., but many of them weigh 800 lbs.

The manufactures of this county are neither numerous nor extensive, except those carried on at Portsmouth in connection with the Royal Navy. Besides the ship-building in the royal yard, many vessels, both for war and trade, are built on the River Itchen at Buckler's Hard, on the River Boldre, and on the banks of Southampton Water. The manufacture of woollen goods upon a small scale is carried on at Andover, Romsey, Alton, and Basingstoke. Paper is made at Romsey and at Overton. The mills at the latter place have supplied the whole of the thin paper used by the Bank of England for their notes ever since the reign of George I. Ringwood has been long celebrated for the excellence of the strong beer brewed there, but the quantity has declined of late years. On the sea-shore at Lymington, and on the island of Hayling, near Havant, some salt is made by the evaporation of sea-water. The quantity depends on the degree of heat which prevails during the summer season, as the first part of the process of evaporation is performed by the heat of the sun alone; the brine is afterwards conveyed to iron pans, and the process completed by artificial heat. But as coal is the only fuel, the process is expensive, and prevents the proprietors from competing with the northern manufacturers of salt.

The foreign commerce of the county was inconsiderable until the formation of the Southampton Docks, and the consequent rise of that place as a commercial port. Its commerce even now can by no means be compared with that of several other counties—Southampton being principally used as a steam-packet station. That port, however, imports much wine from Portugal, which, before the introduction of the bonding system, used to be deposited in the islands of Guernsey and Jersey, to save the interest upon the amount of the duties. It also carries on a considerable commerce with the Baltic. At Christchurch there are a few vessels fitted for the Newfoundland fishery.

The most considerable towns, with their population, according to the census of 1851, are:—

Towns.	Pop.	Towns.	Pop.
Portsmouth and Portsea	72,126	Basingstoke	4,275
Southampton	34,092	Lymington	4,166
Winchester	12,079	Ringwood	3,933
Fareham	5,843	Alton	3,300
Romsey	5,649	Fordingbridge	3,178
Andover	5,195		

These will be found described in their alphabetical order in other parts of this work.

Aldershott, a little village on the borders of Surrey, has become of late a place of some note, by the formation of a military camp on Aldershott Heath. The camp is constructed at the base of a range of hills on the left of the road leading from the town of Farnham. It is at present formed entirely of wooden huts, but permanent barracks are in course of construction. When completed, the huts will afford accommodation for 20,000 militia, and the barracks for 10,000 regulars, consisting of cavalry, infantry, and artillery. The cost of the whole erections will be upwards of L.300,000.

The antiquities of this county are very numerous, and may be contemplated in the ruins of numerous castles, abbeys, and shattered towers, which add not a little to the beauty of the scenery. The most remarkable are Calshot Castle, Netley Abbey, Hurst Castle, Porchester Castle, and Beaulieu Abbey. Antiquities of more early date, of ancient British or of Roman origin, are scattered over the county. The numerous barrows are ascribed to the former, and many vestiges of intrenched camps and castles to the latter.

The beauty of the county has attracted to it a greater number of families of rank and fortune than almost any other county can enumerate. The principal seats alone number nearly 300.

By the Reform Act of 1832, this county has, for election purposes, been divided into the northern and southern parts, each of which returns two members to the House of Commons. The place of election for the northern division is Winchester; and the other polling places are Fareham, Lymington, Ringwood, and Romsey. By the same law the boroughs of Whitchurch and Stockbridge were disfranchised; and the boroughs of Petersfield and Christchurch, which used to elect two members, now choose only one each. The towns which now return two members each are Winchester, Southampton, Andover, Lymington, and Portsmouth, with which is incorporated the adjacent large town of Portsea.

The whole population of Hampshire amounted in 1801 to 219,656; in 1811, to 245,080; in 1821, to 283,208; in 1831, to 314,700; in 1841, to 355,004; and in 1851, to 402,033 (199,834 males, and 202,199 females); so that in half a century the county has nearly doubled the number of its inhabitants. It appears by the register of burials that the deaths between 1801 and 1811 were 1 in 46 of the inhabitants; that from 1811 to 1821 they were 1 in 54; and from 1821 to 1831 (notwithstanding an increase of mortality by the cholera) 1 in 56. In these years, therefore, there was a continued and marked decrease in the rate of mortality; but within the last few years there has been a perceptible increase, caused, without doubt, by the great and rapid augmentation of the population of the large towns. According to the latest averages, the mortality of the county is still below that of the whole country, and this we think may be accepted as a proof of the general salubrity of its climate.

According to the census returns of 1851, there were then 818 places of worship in the county, containing 214,674 sittings. Of these places of worship, 389 belonged to the Church of England, 116 to Independents, 69 to Baptists, 190 to Methodists, 13 to Roman Catholics, 7 to Latter-Day Saints, 6 to Quakers, 6 to Unitarians, and the rest to minor bodies. There were 1508 day schools, with 57,960 scholars; of these 487, with 39,906 scholars, were public schools; and 1021, with 18,054 scholars, were private schools. Of the public schools, 25 were supported by general or local taxation, 59 by endowments, and 386 by religious bodies.

There were also 576 Sunday-schools; of which 322 belonged to the Church of England, 98 to Independents, 58 to Wesleyan Methodists, 45 to Baptists, and the rest to other bodies. Of evening schools for adults, there were 33, with 677 scholars.

HAMPSTEAD, a village in the county of Middlesex, 4 miles N.W. of London. Its pleasant situation, on a considerable eminence commanding extensive views, and the salubrity of its atmosphere, render it a favourite place of residence and of resort. The hill, on the southern slope of which the village stands, is the loftiest site near the metropolis, being 443 feet above the level of the Thames, or 36 feet higher than the cross of St Paul's. The extensive heath on the summit of the hill covers an area of about 280 acres. The streets are mostly narrow and tortuous, lined with houses of all kinds, from the mere cottage to the spacious mansion. The parish church, erected in 1747, and enlarged in 1844, is a building in the Italian style, having accommodation for 1600 persons. East of the town is a mineral spring which was in high repute during the seventeenth century, at which time Hampstead was a fashionable watering-place. In the vicinity are numerous villas. Pop. of parish (1851) 11,986.

HAMPTON, a village in the county of Middlesex, on the N. bank of the Thames, 12 miles W.S.W. of London. The parish church is a handsome edifice having a square tower at its western end. There are numerous elegant villas in the vicinity. Hampton Court Palace, a deserted abode of royalty, stands close to the river about a mile from the village. It was originally erected by Cardinal Wolsey, and presented by him to his royal master Henry VIII., who made some additions to it. The original edifice consisted of five quadrangles, of which only two now remain, but a third was erected by Sir C. Wren for William III. The western quadrangle has undergone little alteration since Wolsey's time, and is a good specimen of Tudor architecture. The middle quadrangle, called the Clock Court, from a curious astronomical clock placed over the gateway, is of mixed style, the massive character of the old building being marred by the improvements of Kent in 1732. The northern side is wholly occupied by the length of the hall, and on the opposite side is the incongruous colonnade of Sir C. Wren. The third quadrangle was erected, as already said, for William III., under whom also the gardens and park were laid out in their present form. The king's entrance in the Clock Court leads to the grand staircase and state apartments. Hampton Court contains an extensive and valuable collection of pictures, including a large collection of portraits of persons connected with English history, by Holbein, Lely, Kneller, West, &c.; and the celebrated cartoons of Raffaele, seven in number, representing some of the most striking incidents recorded in the New Testament. Hampton Court became the favourite residence of Henry VIII. Edward VI. was born here, and here his mother Jane Seymour died. James I. and his son Charles I., Cromwell, Charles II., James II., William III., Queen Anne, and George II. made this their occasional or more permanent residence. It is now open to the public free of charge, and part of it is occupied by persons of rank in reduced circumstances.

HAMSTER. See index to MAMMALIA.

HANAPER, formerly an office in Chancery, but abolished by 5th and 6th Vict. c. 103. It was under the direction of a master, his deputy and clerks, and answered in some measure to the Roman *fiscus.* (See FISC.) It received the name of Hanaper from the wicker baskets or hampers (*hanaperia*) in which the writs were anciently kept. Writs relating to the subject were deposited in these hanapers; while those concerning the Crown were kept in a little sack or bag; whence another office of the same court took the name of the Petty or Little Bag.

HANAU, a town of Germany, capital of a cognominal province, in the electorate of Hesse-Cassel, on the Kinzig, near its junction with the Main, 12 miles E. of Frankfort-on-the-Maine, with which it is connected by railway. It consists of an old and a new town; the former is ill-built, with narrow and irregular streets, but in the latter the buildings are of a better class, and the streets are generally broad and regular. Its ancient castle in the old town is now the seat of the Wetteravian Society of Natural History. The market-place in the new town is a large oblong parallelogram with handsome fountains in the four corners, and the large town-hall at one end. Hanau possesses four Calvinistic churches, a Roman Catholic church, synagogue, hospital, theatre, gymnasium, and several scientific and literary associations. This is the principal commercial and manufacturing town in the electorate. Its industrious products comprise silks, ribands, cottons, carpets, leather, gloves, stockings, hats, tobacco, gold and silver wares, musical instruments, carriages, &c. It has also a large trade in wine, timber, casks, carriages, &c. Here, on 30th October 1813, Napoleon, in his retreat from Leipzig, totally defeated a very superior force composed of Bavarians and other allied troops, under Marshal Wrede. Near Hanau are the electoral palace of Philippsruhe and the watering-place of Wilhelmsbad. The province of Hanau has an area of 535 square miles, and contained 124,328 inhabitants in 1854.

HANCES, HANCHES, HAUNCHES, or HANSES, in *Architecture*, certain small intermediate parts of arches between the crown and the spring at the bottom, being probably about one-third of the arch, and placed nearer to the bottom than the top, which are likewise denominated the *spandrels.*

HAND. See ANATOMY, vol. iii., p. 33, &c.; also, Sir Charles Bell's treatise *On the Hand.*

HAND, a measure of four inches, or a handsbreadth; used in measuring the height of horses. The term is also used to denote the fore-foot of a horse.

Imposition, or laying on of HANDS, signifies the conferring of holy orders; a ceremony in which the hands are laid on the head of a person as a sign of a mission, or of a power given him to exercise the functions of the ministry belonging to the order. The apostles began to appoint missionaries by the imposition of hands.

HANDEL, GEORGE FREDERIC, the most illustrious of musical composers, was born at Halle, in Upper Saxony, Feb. 24, 1684. His father was an eminent physician of the same place, and upwards of sixty years old when this son, the issue of a second marriage, was born. From his very childhood Handel discovered a passion for music which could not be subdued by the commands of his father, who intended him for the profession of the law. Notwithstanding that he was forbidden to touch a musical instrument, the boy found means to get a little clavichord conveyed secretly into one of the attics of the house. To this room he constantly repaired when the family had retired to rest, and, by his assiduous labours at the midnight hour, made considerable progress in his favourite pursuit.

It happened, when Handel was about seven years old, that his father had occasion to pay a visit to a son by a former wife, who was then serving as attendant to the Duke of Saxe-Weissenfells. Handel implored that he might be permitted to accompany him; and, on being refused, he followed the carriage some way on the road, till he overtook it. His father at first chid him for his disobedience; but, yielding to his solicitations, at last took him into the carriage. During his stay at the ducal residence, he continued to show the same irresistible inclination for music. He could not be kept away from harpsichords, and he contrived to gain admission into the organ gallery at church, and to play when the service was over. Upon one of these occasions the duke, who happened to leave the chapel later than usual, was attracted by the uncommon style in which the instrument was touched. Inquiring who played, he heard to his astonishment that it was a boy of seven years of age. The duke immediately desired to see young Handel, and was so much pleased with his precocious genius, that he prevailed upon his father to allow him to follow the bent of his inclinations. He made the boy a present, and told him that if he was attentive to his studies he should not want encouragement.

On his return to Halle, Handel was placed by his father under Zachau, organist of the cathedral church of that city; a man of considerable abilities, and proud of his pupil. By the time he was nine years old, our young musician was not only able to supply his master's place at the organ, but began to study composition. At this early period of his life, he wrote a service, or *spiritual cantata*, every week, for voices and instruments, and continued this labour for three years successively. He also composed sonatas for the oboe, which was his favourite instrument.

Handel appears to have studied in his native city till he was about the age of fourteen. He then, as Zachau himself acknowledged, far excelled his master; and it was recommended to his father to send him to Berlin. Thither he accordingly went in 1698. The opera at Berlin was then in a very flourishing state, under the direction of Buononcini and Attilio. Handel distinguished himself in this city as an astonishing musician for his years, and gave earnest of such great talents that the elector of Brandenburg offered to take him into his service, and send him to Italy to complete his studies. But his father declining this honour, from a spirit of independence, Handel returned to Halle. Not long after this, his father died, and Handel not being able to go to Italy on account of the expense, removed to Hamburg, in order, by his musical talents, to procure a subsistence.

Mattheson, an able musician and voluminous writer on music, who resided at Hamburg, tells us that Handel arrived there in the summer of 1703. "Here," says Mattheson, "almost his first acquaintance was myself, as I met him at the organ of St Mary Magdalen's Church, July the 30th, whence I conducted him to my father's house, where he was treated with all possible kindness as well as hospitality; and I afterwards not only attended him to organs, choirs, operas, and concerts, but recommended him to several scholars. At first he only played a *ripieno* violin in the opera orchestra; and being naturally inclined to indulge in a kind of dry humour, pretended unusual ignorance, in a manner that made the most serious people laugh, though he preserved his own gravity. But his superior abilities were soon discovered; for the harpsichord player of the opera having been absent for a time, Handel was persuaded to take his place, and on this occasion showed himself to be a great master, to the astonishment of every one, except myself, who had frequent opportunities of knowing his abilities on keyed instruments."

Mattheson and Handel became intimate acquaintances, and did not allow any professional rivalship to interfere with their friendship, until the occurrence of the following adventure. Mattheson had composed an opera called *Cleopatra*, which was performed in Hamburg, and in which he acted the part of Antony himself, and Handel played the harpsichord. Mattheson was accustomed, upon the death of Antony, which happened early in the piece, to preside at the harpsichord in the character of composer; but one evening Handel refused to indulge his vanity by relinquishing this post to him. This occasioned so violent a quarrel between them, that, on going out of the house, Mattheson gave him a blow on the face; upon which both immediately drew their swords, and a duel ensued in the market-place, before the opera-house. Luckily the sword of Mattheson broke against a metal button on Handel's coat, or, as some allege, a score of music which he carried under it, which put an end to the fight.

This rencontre happened upon the 5th of December 1704; but, as a proof of a speedy reconciliation, Mattheson mentions, that on the 30th of the same month, he accompanied the young composer to the rehearsal of his first opera of *Almira*, at the theatre, and performed the principal part in it; and that afterwards they became greater friends than ever. Whilst he remained at Hamburg, Handel composed his opera of *Nero, oder Die durch Blut und Mord erlangte Liebe*, which was very successful. He also produced two operas entitled *Florinda*, and *Dafne*, and wrote innumerable songs, cantatas, and pieces, for the harpsichord. His style, Mattheson allows, was greatly improved by his constant attendance at the opera; and he was esteemed a more powerful player on the organ than the famous Kuhnau of Leipzig, who was at this time regarded as a prodigy.

Handel having now acquired, by his operas at Hamburg, a sum sufficient to enable him to visit Italy, he set out for that seat of the muses. He stayed some time at Florence, where he composed his opera of *Rodrigo*. From this city he went to Venice, where, in 1709, he produced his *Agrippina*, which was received with acclamation, and had a run of thirty nights. Here he met with Domenico Scarletti, Gasparini, and Lotti. He next visited Rome, where he had an opportunity of hearing compositions and performers of the first class. At Cardinal Ottoboni's, by whom Handel was greatly caressed, he had frequently the advantage of hearing the celebrated Corelli perform his own works. During his stay at Rome, our young composer produced a serenata entitled *Il Trionfo del Tempo;* after which he went to Naples, where he set *Acis and Galatea* in Italian.

Handel returned to Germany about the beginning of the year 1710, and was made *Kapellmeister* to the elector of Hanover, afterwards George I. He does not appear, however, to have remained long in the service of the elector, but bent his course to London, where a passion for dramatic music had already manifested itself in several awkward attempts at operas, and to which place he had received invitations from several of the nobility he had seen in Italy and Hanover. His reception in England was flattering to himself and honourable to the nation, at this time no less successful in war than in the cultivation of the arts of peace. To the wit, poetry, literature, and science, which marked this period of our history, Handel added all the blandishments of a nervous and learned music, which he first brought hither, planted, and lived to see grow to a very flourishing state. The first opera he wrote in England was *Rinaldo*, taken from Tasso's *Gierusalemme*, which at once established his reputation. He afterwards produced his *Pastor Fido*, *Theseus*, and, in 1715, *Amadis da Gaula*. In all of these, Nicolini and Valentini, the first Italian singers that appeared in England, performed. When the peace of Utrecht was brought to a conclusion, Handel was employed to compose the Hymn of Gratitude and Triumph on the occasion. The grand *Te Deum* and *Jubilate* he produced was composed with such force, regularity, and instrumental effect, as to excite universal delight.

On the arrival of George I. Handel was honoured with the most flattering marks of royal favour from the king and queen, who added largely to the pensions previously conferred on him by Queen Anne.

We now come to the busiest and most glorious period of Handel's life. His great natural powers had been highly improved by cultivation; his genius for composition was unbounded; he stood at the head of his profession, esteemed alike by the sovereign, the nobility, and the public, of a great and powerful nation, at a period of its greatest happiness and prosperity. Such were Handel's circumstances, when the Royal Academy, or an association for the establishment of an Italian opera in England, was formed.

Handel was appointed director and composer, engaged singers, and, although he had to contend with several rivals, at length, by the superior grandeur and invention of his operatic music, distanced them all. About this period of his career Handel unfortunately became involved in a quarrel with the vocalist Senesino, the particulars of which we pass over. The result was to break up the academy; and it not only proved injurious to the fortune of our composer, but was the cause of infinite trouble and vexation to him during the rest of his life. From the institution of the academy till its dissolution in 1729, Handel produced about thirty operas. The greater part of these had immense success; yet such was the influence of opposition and neglect, that none of his operas composed subsequently to 1740, although actually his highest achievements in operatic composition, were received with the admiration due to their merit.

Following the narrative of Burney in his sketch of Handel's life, we leave his dramatic transactions, and come now to notice the sacred dramas or *oratorios* of this great musician. The oratorio of *Esther* was the first he composed; and in 1733 *Deborah* was given to the public. It was during these early performances of oratorios that Handel first played his organ concertos, a species of music wholly of his own invention, in which he usually introduced an extempore fugue, a diapason-piece, or an adagio, displaying not only great fertility and readiness of invention, but the most perfect accuracy and nicety of execution. In 1735 he produced *Acis and Galatea*, and *Alexander's Feast;* in 1738, *Israel in Egypt;* and in 1739, *L'Allegro ed il Penseroso*. In 1740 the oratorio of *Saul* was performed at the theatre in Lincoln-Inn Fields; and from this period Handel almost entirely devoted his labours to the service of the church. The profits arising from the performance of his oratorios were not sufficient to indemnify his losses; and it remains a stigma upon the taste of the nation, that the *Messiah* at first proved neither successful, nor remunerative to the composer. Chagrined with repeated disappointments, Handel went to Ireland, in order, as Burney remarks, "to try whether his oratorios would be out of the reach of prejudice and enmity in that kingdom." In allusion to this, Pope wrote his well-known lines, supposed to be addressed by the poet personifying the Italian opera, to the goddess of Dulness.

> "Strong in new arms, lo, giant Handel stands,
> Like bold Briareus, with his hundred hands;
> To stir, to rouse, to shake the soul he comes,
> And Jove's own thunders follow Mars' drums,
> Arrest him, empress, or you sleep no more:—
> She heard, and drove him to the Hibernian shore."

After remaining about nine months in Ireland, where his exertions were successful, Handel returned to London, and produced *Samson* and the *Messiah*, which latter work was now received with universal applause. This truly sublime oratorio was performed annually at the laudable and benevolent instigation of the author, and under his direction, for the benefit of the Foundling Hospital; and the produce of these performances, from the year 1749 to the year 1777, amounted to nearly L.10,300. Although the *Messiah* was performed almost always to crowded houses, the other oratorios were but thinly attended. This was owing no less to the capriciousness of public taste than to the extraordinary hostility of some of his powerful adversaries. The king, however, continued his steady patron, and attended his oratorios when they were neglected by the rest of the court.

Towards the close of his life Handel was afflicted with blindness, which, however, did not affect his faculties, as he continued to play to the last with his wonted vigour. "To see him, however," says Burney, "led to the organ after this calamity, at upwards of seventy years of age, and then conducted towards the audience to make his accustomed obeisance, was a sight so truly afflicting and deplorable to persons of sensibility, as greatly diminished their pleasure in hearing him perform." It was remarked, that with many parts of his music he was unusually agitated, particularly with that affecting air in *Samson*, "Total eclipse—no sun, no moon," which so peculiarly applied to his own situation. The last oratorio he attended and superintended was upon the 6th of April, and he expired on Friday the 13th, or Good Friday 1759, the very day he had seriously wished that event should happen, "in hopes," as he said, "of meeting his good God, his sweet Lord and Saviour, on the day of his resurrection," meaning the Easter Sunday following.

The musical powers of Handel can perhaps be best expressed by Arbuthnot's reply to Pope, who seriously asked his opinion of him as a composer. "Conceive," said he, "the highest you can of his abilities, and they are much beyond anything you can conceive." He excelled in almost every style of composition. The church, the theatre, and the chamber, were equally adorned by his talents. The best of his Italian operas are superior in variety and ingenuity to those of all preceding and contemporary composers throughout Europe. In his full, masterly, and admirable organ fugues, upon remarkably natural and pleasing subjects, he has surpassed the most renowned writers in this difficult and elaborate species of composition; and every judicious and unprejudiced musician, when he hears or peruses the noble, majestic, and sublime oratorios and anthems of Handel, must allow, with readiness and rapture, that they are unacquainted with any thing equal to them among the works of the greatest masters that have existed since the invention of counterpoint. (*Memoirs of the Life of G. F. Handel*, 1760. Consult Townsend's *Account of the Visit of Handel to Dublin.*) (A.H.)

HANDSPIKE, a wooden bar or lever used on board ship in working the windlass.

HANG-CHAU-FOU, an important city of China, capital of the province of Che-kiang, on a plain near the River Tsientang, about 40 miles from its mouth, and 140 miles S.E. of Nanking. It is surrounded by high and strong walls, said to be 9 miles in circumference; and adjoining it are very extensive suburbs. The Governor-General of Che-kiang and Fu-kien resides in this city, and also the governor of the province, which, with their courts and troops, in addition to its great trade, render this one of the most important and richest cities in the empire. A portion of the space within the walls is divided off for the accommodation of a garrison of 7000 troops. The Grand Canal has its southern termination here in a large irregular basin. The streets are well paved; and the shops and warehouses are large and well stored with goods. There are numerous rich temples and elegant public buildings; and altogether this city presents the appearance of great wealth and splendour. It is noted for its silk manufactures, which employ a large portion of its inhabitants. The population is said to be about one million.

HANGO HEAD, a promontory on the north coast of the Gulf of Finland, at its mouth, in N. Lat. 59. 46. 20.; E. Long. 22. 58. In 1714 the Swedes were defeated in a naval engagement by the Russians off this point; and on 5th June 1855, an English boat's crew, while landing Russian prisoners under a flag of truce at the village of Hango, were attacked by troops under cover, when ten or twelve men were killed, and the others captured.

HANLEY, a town of England, county of Stafford, near the centre of the pottery district, 16 miles N. of Stafford. It is indebted for its rise and present importance to the potteries, which afford employment to nearly its entire population. The parish church is a handsome building, with a fine tower 100 feet in height. The township of Hanley is, for local purposes, united with that of Shelton into one market-town, which, in 1851, contained 25,369 inhabitants. Hanley is included in the parliamentary boundaries of Stoke-upon-Trent.

HANNIBAL, a Carthaginian general, son of Hamilcar Barcas, was born 247 B.C., in the eighteenth year of the first Punic War, the same year in which his father first took a prominent part in public affairs. His family was one of the most distinguished in Carthage, and, claiming to be descended from the ancient kings of Tyre, it ruled its native city with almost regal power. The history of Hannibal forms an epoch in the destinies of Rome. We can have little difficulty in forming a true estimate of his character when we know that, almost unaided by his countrymen, he sustained for upwards of sixteen years a struggle for the empire of the world with a nation which had hitherto been victorious in every contest it had undertaken, and had at its disposal the resources of the greater part of Italy. It was the last struggle which the republic of Rome maintained for existence; and there was none which called forth more conspicuously the energies of her mighty warriors, or displayed more fully their unconquerable perseverance and undaunted bearing in the most untoward circumstances. If Hannibal had been properly supported by his countrymen at home, the star of Rome would probably have set for ever, and Carthage would then have stood forth as the conqueror of the world, and the source of civilization. The key to all Hannibal's proceedings is to be found in his hatred of the Romans, a feeling indelibly impressed upon his mind by his father when he made him swear at the altar of his country that he would pursue the Romans with unrelenting hatred.

The military education of Hannibal must have commenced from boyhood, but of his early years we have no detailed account. He was eighteen years of age on his father's death (229 B.C.), and probably spent the greater part of the next eight years in the camp of his brother-in-law Hasdrubal, who had succeeded to the command of the troops in Spain on the death of Hamilcar, and who pursued the same line of policy as his predecessor, in trying to obtain entire possession of the resources of Spain as a means of attacking Rome. Private revenge cut off Hasdrubal in the midst of his career (221 B.C.), and the soldiers by acclamation raised Hannibal to the vacant command. The appointment was ratified by the senate at home, and from this moment Hannibal regarded Italy as his province, and war with Rome as the only object worthy of his attention. The conciliatory measures of Hasdrubal had succeeded in uniting the greater part of the nations of Spain to the dominions of Carthage; and those who still maintained independence Hannibal determined to reduce at once by the energy and activity of his proceedings. He led his troops into the country of the Olcades, a people who seem to have been situated in the mountainous district of Cuença, near the sources of the River Xucar; and having taken their chief city, he entirely defeated them. He was equally successful in his attack on the Vaccæi, a people inhabiting the country round Salamanca; and having subdued all the nations south of the River Ebro, except the Saguntines, he was prepared to complete his conquests by the reduction of their city.

The attention of the Romans, which had latterly been much occupied with the affairs of the north of Italy, was now drawn towards Spain, and they became alarmed at the proceedings of Hannibal. An embassy from Saguntum roused them to active measures, and deputies were hurried off to remonstrate with Hannibal for his interference, contrary to treaty, with an ally of the Roman people. Polybius enters into a discussion whether we ought to consider this attack on Saguntum as the real cause of the second Punic War, and wisely, we think, decides that it was merely the pretext. We must go farther back, and search more deeply, to discover the real motives which induced the Carthaginians to support Hannibal in his attack on Rome. It was the unfair advantage that had been taken to wrest from them Sardinia, that had made an indelible impression on the minds of the Carthaginians; and the Barcine faction, which was now headed by Hannibal, used all its influence to keep alive the national feeling of hatred to Rome. There was indeed a party for peace, headed by Hanno, but their feeble voice was drowned amidst the din of warlike preparations. Hannibal was already busily engaged in the siege of Saguntum, a city situated on the east of Spain, about one mile from the sea, and the ruins of which are still to be seen near Murviedro (*Muri Veteres*), when the Roman deputies made their appearance, and demanded an audience. This was refused by Hannibal, under pretence that he could not guarantee their personal safety in the midst of so many barbarous nations; and the deputies found themselves obliged to continue their journey to Carthage. Here they were not more successful, and immediately returned to Rome to hasten the preparations for war. Meanwhile Hannibal continued the siege of Saguntum, which was defended with all the obstinacy for which the Spaniards have ever been distinguished; but it was at last taken, after a brave resistance of eight months, and delivered over to all the horrors of pillage. Thus the way was cleared for an attack on Italy; and though the Romans had evidently never imagined it possible that such a daring measure would for a moment be entertained, it is quite clear that Hannibal, from the first day of his command, had resolved to put it into execution without delay. The Romans intended that Spain should be the scene of action; but Hannibal boldly determined to attack them in the very centre of their power, on the plains of Italy.

Hannibal spent the winter of 219 B.C. in preparations for his gigantic undertaking, and omitted nothing which he thought likely to forward his object. He allowed many of his soldiers to visit their homes, as it might be their last opportunity; he drew up instructions for the use of his brother Hasdrubal, who he intended should govern Spain in his absence; and prudently secured the maintenance of peace in both Africa and Spain, by an exchange of the troops of the two countries. Neither did he neglect to make himself acquainted with the feelings of the people through whose territory he must pass in his way to Italy, and sent secretly to Cisalpine Gaul to secure the co-operation of the disaffected tribes as soon as he should make his appearance amongst them. He discovered also that the passage across the Alps was practicable, though it might be attended with great difficulty.

Having thus made his preparations, Hannibal began his march from Carthago Nova, now Carthagena, in the beginning of spring 218 B.C., with an army of 90,000 foot and 12,000 horse. As the River Ebro had been made by treaty the boundary between the Roman and Carthaginian portion of Spain, he found all the tribes at the foot of the Pyrenees ready to dispute his passage, and he did not reduce them without a considerable diminution of his forces. He found, besides, many of his Spanish soldiers frightened at the dangers which lay before them, and, making a virtue of necessity, he sent a considerable portion of them back. The troops that passed the Pyrenees were thus reduced to 50,000 foot and 9000 horse; but they were mostly men whose bodies were inured to hardships by a long course of war. Hannibal had reached the banks of the Rhone before the Romans were aware that he had moved from Carthagena; and Publius Scipio, who had been dispatched with sixty ships towards Spain, was much surprised to find, on reaching the mouths of the Rhone, that Hannibal was in that neighbourhood. He landed his troops, and prepared to attack Hannibal; but the energy of that general had anticipated his intention, and the first slopes of the Alps were already ascended before Scipio moved from his position. The road which Hannibal pursued across the Alps is a much disputed point, but this is not the place to enter at any length into such a subject. We feel more confidence in the statements of Polybius—who tells us (iii. 48) that he had examined the passages of the Alps with great care—than in those of Livy, who, though admirable for the beauty of his style, has no pretensions to geographical accuracy. Yet, even from Polybius, all that we can gather with certainty is, that Hannibal passed the Alps to the north of the River Isara (Isère), and descended into the Insubrian territory in Italy. It was therefore across the Alpes Graiæ (Little St Bernard) that he passed, and not the Alpes Cottiæ (Mount Genevre), as Livy, and Strabo (iv. 209) evidently think. But be this as it may, Hannibal succeeded in crossing the Alps in fifteen days, though not without great difficulty, and the loss of many of his troops. He found, on examination, that he had not more than 20,000 infantry and 6000 cavalry. The whole journey from Carthago Nova had occupied five months.

Scipio had no sooner convinced himself that Hannibal was serious in his intention of crossing into Italy than he hurried back with part of his troops, and, to the astonishment of Hannibal, was ready on the banks of the Po to oppose his progress. It was necessary for Hannibal that a conflict should immediately take place, to confirm the wavering minds of the Gauls; and the battle fought on the banks of the River Ticinus, in which he defeated Scipio, and compelled him to retire beyond the Po, was the signal for a general rising. Hannibal pursued Scipio across the river, and found that he had taken up his position on the banks of the River Trebia, near to Placentia (Piacenza). Scipio now saw that his true policy was to weary out Hannibal, and to give him no opportunity of attacking; but the Roman general was wounded, and could take no active part in the proceedings. His colleague, Tiberius Sempronius, elated by some partial success, ventured beyond the intrenchments, and the result was the speedy and complete defeat of the Romans. Placentia soon afterwards fell into his hands; and thus, within a couple of months, the whole of the north of Italy was at his disposal. The Romans heard this intelligence with great dismay, but took active measures to maintain the contest. The two consuls now took a position where they could watch the proceedings of Hannibal, who would naturally advance to the south as soon as the rigour of the winter months had abated. Accordingly, in the beginning of spring, 217 B.C., Hannibal crossed the Apennines into Etruria, by a road, the position of which has been as much disputed as that by which he passed the Alps. We are satisfied with Vaudoncourt, who has minutely examined this point, that he crossed the Apennines by the road which leads from Parma to Pontremoli and Sarzana; and that the marshes, where Hannibal had nearly lost his life, are those now called Paludi di Fuccechio, a little above the place where the Arno falls into the sea.

Hannibal found the consul Flaminius posted at Arretium, a city situated on the slopes of the Apennines, and ready to dispute his advance. He laid waste the country on every side, and drew Flaminius into an ambuscade which he had laid for him on the banks of the Thrasymene Lake, where the consul fell, and his whole army was defeated. The road to Rome was now open to him; and it has often been matter of surprise that he did not march directly upon the city, and by one bold stroke put an end to the war. We have no means of knowing the reasons which deterred him from this obvious proceeding; but he turned to the east, at the city of Spoletium (Spoleto), and proceeding through Umbria and Picenum, where he seems to have met with no resistance, he entered the rich province of Apulia, where he wintered. The following year, 216 B.C., he found himself opposed by the cautious policy of Fabius; and though Hannibal used every means to provoke the Roman general to action, his temper and prudence were proof against every attack. Towards the end of the year, however, Hannibal again asserted his superiority; and the battle of Cannæ, fought at a small village of Apulia, on the banks of the Aufidus, on the 2d of August, was as celebrated a defeat as the Romans had ever sustained. Fortune now again seemed to point the way to Rome; and it seems impossible not to feel convinced that Hannibal committed an unpardonable blunder in not attacking the city itself. He wintered at Capua, and the enervating luxury of that district is said to have entirely changed the character of his soldiers. The progress of Hannibal was by no means so rapid as might have been anticipated from his victories. Many of the cities of Campania made a successful resistance; and the obstinacy with which they maintained their alliance with the Romans proves that the sway of that people must have been by no means burdensome. It appears to us that the failure of Hannibal was chiefly owing to the small number of his troops, which did not enable him to garrison the cities which he took, or to station bodies of men in various parts of the country to repress insurrectionary movements. Nor do the Carthaginians seem to have entered into the contest with that spirit which the greatness of the prize might have fully justified. Had the number of his men enabled him to follow up his victories by active measures, there can be no doubt that Rome must have fallen into his hands.

The next year produced no action of any importance on either side, though Hannibal gradually lost ground. He pressed earnestly for reinforcements; and his brother Hasdrubal crossed the Alps with a considerable body of troops, 207 B.C., which might again have changed the aspect of affairs. Fortune, however, had deserted him; for Hasdrubal fell in an engagement on the banks of the River Metaurus, and his army was entirely defeated. Hannibal was now left to his own resources, and he was obliged to confine himself to defensive measures. Meanwhile Scipio had commenced his career of conquest in Spain, and had subdued the whole country as far as Gades. He crossed into Africa, and, assisted by Masinissa, attacked the Carthaginians in their own territory. Hannibal was thus obliged to return to the defence of his country, 203 B.C., after he had maintained his footing in Italy for sixteen years. The battle of Zama, fought in Africa, 202 B.C., in which Hannibal was completely defeated, left nothing for the Carthaginians but humble submission to the conqueror. Peace was granted, though on hard conditions; and Hannibal now took an active part in the domestic arrangements of his country. He attempted to reform the numberless abuses which had crept into the constitution; but he at the same time excited the enmity of the great body of the aristocracy, who were ready to seize the first opportunity of banishing him. They accused him to the Romans of keeping up an active communication with Antiochus, king of Syria, then supposed to be preparing war against them; and when the Romans sent three commissioners to take cognizance of the affair, Hannibal did not choose to await the result, but fled towards the east, and reached Tyre in safety. Here he stayed a few days, and was received with much honour; whilst at Carthage his property was confiscated, and his house razed to the ground. He then proceeded to Ephesus, where he was kindly welcomed by the king, and consulted as to the best mode of attacking the Romans. With Antiochus he remained several years, though his advice was by no means always listened to. At last, when Antiochus was defeated, 190 B.C., the king was unable any longer to protect him from the vengeance of his enemies. He therefore fled first to Crete, and afterwards to Prusias, king of Bithynia, where he resided several years, and assisted him in his war against Eumenes, king of Pergamus, the ally of the Romans. Here, too, the vengeance of his enemies reached him. Ambassadors from Rome demanded that he should be given up;

and as Prusias was ungenerous enough to accede to the demand, Hannibal resolved to free himself from all further persecution, and swallowed poison, which he always carried with him. In what year he died is a point in which the ancients do not agree. According to Atticus (apud Nep. Hannib., c. 13), and Valerias Antias (apud Liv. xxxix. 56), and Cassiodorus, it was 183 B.C., the same year in which Philopœmen and the elder Scipio died. Polybius, however, makes it 182, and Sulpicius 181 B.C. Thus died the most celebrated of the Carthaginians, the only man who could have saved his country from ruin, and restored it to its ancient glory.

HANNO, a Carthaginian, celebrated for a voyage of discovery along the western coast of Africa; but at what period it was made is not known with any degree of certainty. The different writers who have examined the point have fixed him at various periods between 1000 and 300 B.C.; but we are inclined to agree with Rennel, who thinks he must have lived about 570 B.C. The principal object of this expedition is set forth in the journal, which begins with these words:—"It was decreed by the Carthaginians that Hanno should undertake a voyage beyond the Pillars of Hercules, and found Libyphœnician cities. He accordingly sailed with sixty ships, of fifty oars each, and a body of men and women to the number of 30,000, and provisions and other necessaries." It is much to be regretted that this curious remnant of antiquity should have been exceedingly brief, and that it should not have come down to us in its original form, for it is evidently a mere abstract of a larger work. Some, indeed, have endeavoured to strip it of all pretensions to credit, and to rank it with the Arabian tales; but though some of the stories may have the appearance of fable, such as *fiery torrents* and *women covered with hair*, the facts, which are susceptible of verification, either by the test of geography or a comparison with the descriptions of travellers, are of too consistent a nature to allow us to doubt that the voyage was really undertaken. It would appear that the first city was founded at no great distance from the Strait of Gibraltar, the rest to the north of Cape Bojador. This voyage extended a little to the south of Sierra Leone; but we must refer the reader to the writers who have examined the subject for a detailed account of his geographical statements. The title of the Periplus is, *An Account of the Voyage of Hanno, Commander of the Carthaginians, round the parts of Libya beyond the Pillars of Hercules, which he deposited in the Temple of Saturn.* It has been published by Hudson (*Geogr. Min.*, vol. i.), and Falconer (Oxford, 1797), with an English translation and explanations; also by Kluge, *Hannonis Navigatio, textum critice recogn. et adnotat. illustravit*, Leip. 1829. The following authors have also published commentaries on the voyage, viz., Bochart, Campomanes, Dodwell, Bougainville, Gosselin, Heeren, and Rennell.

HANNO, a senator of Carthage, who headed the party opposed to the warlike policy of the Barcine faction. He was first appointed to the command of the troops in the interior of Africa, and was successful in reducing Hecatompylos, with the adjoining country. When the mercenary troops which had been employed in the first Punic War became clamorous for their arrears of pay, and at last ventured to make open war on Carthage, Hanno was appointed to the command of the forces to be employed against them. His talents, however, seem to have been by no means fitted for the field, and affairs assumed such a threatening aspect under his mismanagement, that the Carthaginians began to be alarmed for the very existence of their state. They therefore appointed as his colleague Hamilcar Barcas; but the enmity which existed between the generals completely neutralized the good that might have been derived from their abilities. At last, however, the dangerous position of affairs compelled them to forget their differences, and to unite cordially in resisting their common enemy. (Polyb. i. 73–88.)

He continued during his whole life to be the advocate of peace, in opposition to the ambitious policy of Hannibal; and when that general sent his brother Mago, after the battle of Cannæ, to obtain reinforcements, Hanno exerted all his influence to prevent this request being granted, and even proposed that Hannibal should be given up to the Romans. (Liv. xxi., 3, 9; xxiii., 13.)

HANOVER, a kingdom in Germany, formed out of the duchies which formerly belonged to several families of the junior branch of the house of Brunswick. In the course of the revolutionary war, under the influence of France, the dukedoms of Bavaria, of Saxony, and of Wirtemburg had been raised to the rank of kingdoms; and when the overthrow of Bonaparte was accomplished, the dukedoms which had composed the electorate of Hanover were thought by the allied powers of sufficient consequence to be elevated to the same dignity, as, with the additions then made to them, they were nearly equal in extent and population to the other portions of Germany whose rulers had received that rank. It accordingly assumed that grade in 1814, under George III., and was acknowledged as such by all the powers of Europe.

The obscurity in which antiquity has involved the early history of nations can only be in a slight degree cleared up by tracing the origin of the families that maintained the continued rule over them. The ruling family of Hanover has been traced, by the combined efforts and researches of Muratori and Leibnitz, to an Italian origin, in the dark ages, that is, to the princely house of Este; and by Gibbon, from that house up to the descendants of Charlemagne. A Marquis of Este, in the eleventh century, married Cuniza or Cunegonda, an heiress of a princely family in Bavaria, whose son received the name of Guelph, derived from his maternal ancestors, and inherited their dominions, including the dukedom of Bavaria. The grandson of this Guelph, named Henry the Black, and his son named Henry the Proud, acquired by marriage new and extensive dominions on the banks of the Elbe and the Weser; and Henry the Lion, the most powerful prince of his age, was the first of the race who assumed the title of Duke of Brunswick. Under this Henry, who distinguished himself as a great warrior, an uncle wrested from him the southern portion of his territory in Bavaria and Suabia, and left him, at the conclusion of most bitter hostility, in the possession of the northern portion of it. He made the city of Brunswick the capital of his dominions, and, being in possession of the rich silver mines of the Hartz, was enabled to extend his power over the tribes of Northern Germany, inhabiting Holstein, Mecklenburg, and nearly the whole coast of the Baltic Sea.

Henry the Lion was twice married. By his first wife he left no family; and, although by his second wife, who was Maud, the daughter of Henry II. of England, he had several sons, none of them left any issue except William, and under Otho, the only son of William, took place the partition of the house—Brunswick and Luneburg being divided into two dukedoms. The latter branch received the Hanoverian portion as a fief from William Sigefred, bishop of Hildesheim. After the death of Otho, and of his two sons Otho and William, who successively followed, the male line became extinct in 1369. Otho, elector of Saxony, who had married a daughter of William, was, by the influence of the emperor of Germany, Charles IV., invested with the government. He died without issue, having by his testament bequeathed the dukedom to his uncle Wenceslaus, elector of Saxony—a bequest which was contested by Torquatus Magnus, duke of Saxony, but at length was terminated in a compromise, by which Bernard, the eldest son of Torquatus, obtained the dominion, and reigned until 1434. After several successions, the power became vested in

Ernest of Zell, who first introduced the Lutheran religion into his states, and died in the year 1546. The succession since has been,—William, who died in 1592; Ernest, in 1611; Christian, in 1633; August, in 1636; Friedrich, in 1648; Ernest Augustus, bishop of Osnaburg, who was made an elector of the German empire in 1692, and died in 1698; George Louis, who, after the death of his uncle George William, inherited the dukedom of Zell in 1705, and succeeded to the crown of Great Britain by the title of George I. in 1714. He died in 1727, since which period the succession continued the same as in that kingdom, until the death of William IV. in the year 1837, when, by the salique law, the crown descended to the Duke of Cumberland.

The accession of the electors of Hanover to the throne of Great Britain, though it led ultimately to a great extension of territory, did, on the other hand, subject the electorate to sufferings and oppression during the wars between Great Britain and France. At the commencement of the Seven Years' War, a French army invaded it; and the forces under the Duke of Cumberland, being unequal to its defence, were compelled, by the convention of Kloster-Severn, to abandon the country to the invaders. By the peace of 1763 it was again restored to its ancient sovereign. At the renewal of hostilities after the treaty of Amiens, Hanover was once more seized upon by the French, and by them delivered over to the king of Prussia, who ruled it till after his defeat at Jena. It was then incorporated as part of the kingdom of Westphalia, erected in favour of Jerome Bonaparte. This rule was terminated by the battle of Leipsic, by which Hanover, with the rest of Germany, was delivered from French domination, and returned to its ancient sovereigns, with the addition of the provinces of Hildesheim, Osnaburg, East Friesland, Goslar, and some other territories. On the other hand, Hanover gave up the ancient duchy of Lauenburg, which was transferred to Denmark, and some portions or bailiwicks,—a part to Prussia, and a part to the Duke of Oldenburg.

The kingdom of Hanover lies between N. Lat. 51. 18. and 53. 52., and E. Long. 6. 43. and 11. 45.; and is bounded on the N. by the German Ocean, N.E. by the Elbe, which separates it from Denmark, Hamburg, and Mecklenburg, E. and S.E. by Prussia and Brunswick, S.W. by Hesse-Cassel and Prussia, and W. by Holland. The boundaries include the duchy of Oldenburg, which almost completely separates Hanover into two large portions, the connection being maintained by a narrow stripe of land, not more than 6 miles in width, S. of the duchy. A small portion in the S. is separated from Hanover proper by the interjection of part of Brunswick. The entire area amounts to about 9,464,446 acres, or 14,788 square miles, as follows:—

Provinces.	Extent in English Acres.	Population in Dec. 1852.	Number of Dwelling-houses.
Hanover	1,483,698	349,958	48,445
Hildesheim	1,102,089	367,883	52,042
Lüneburg............	2,769,562	338,764	43,835
Stade	1,674,368	279,834	44,031
Osnabruck	1,540,649	261,965	41,027
Aurich	737,968	185,129	30,024
Clausthal	156,112	35,720	3,392
	9,464,446	1,819,253	262,796

The chief cities are Hanover, Hildesheim, Lüneburg, Emden, Osnabruck, Göttingen, Zell, Clausthal, and Goslar.

The province of Hildesheim is somewhat mountainous, and that of Clausthal, containing the Harz, is wholly so, as well as some parts near Göttingen. The other provinces form a part of that extensive plain which commences on the shores of the German Ocean, and terminates on the frontiers of Russia. The whole plain is a sandy soil, resting on a bed of granite, and is generally sterile, except on the banks of the various rivers that water it, or near the cities, where cultivation has been improved by artificial means. The most fruitful part of the kingdom is on the banks of the Elbe and near the German Ocean, where, as in Holland, rich meadows are preserved from being immersed in water, by broad dykes and deep ditches, constructed and kept in repair at great expense.

The most remarkable mountains are those of the Harz Forest, three-fifths of which are in this kingdom, and two-fifths in the duchy of Brunswick. These mountains are not a part of any chain, but rise from a plain in an isolated group, the highest points of which are nearly in the centre. (See Harz Mountains.) They are covered with extensive forests. On their lower sides the trees are of the deciduous kinds, but the summits are exclusively covered with pines. These mountains abound with minerals of almost every kind, and the principal employment of the inhabitants consists either in mining, or in manufacturing the iron and copper into domestic utensils. Some of the mining and manufacturing towns, as Clausthal, Andreasberg, Cellerfeld, and several others, are from 1700 to 1900 feet above the level of the sea; and their population would suffer most severely from the cold of the severe winters, but for the abundance both of wood and fossil coal with which they are supplied.

The whole of the kingdom of Hanover dips towards the north, and the courses of all the rivers are in that direction. These are, *first*, the Elbe, which borders a large part of the dominion, and receives into it the Ohre, which rises in the province of Lüneburg; the Aland and the Jeetze, which come out of Prussia, and are navigable before they terminate in the Elbe; the Ilmenau, which becomes navigable at Lüneburg; the Este, which is navigable to Buxtehude; the Lühe, navigable to Hornburg; the Schwinge, by which vessels reach Stade; the Oste, which passes Harburg, and is navigable to Kirchosters; and the Medem, which runs through the Hadeln-land, and admits large vessels as high as Otterndorf. *Second*, the Weser, which enters the dominions of Hanover at Münden, being there formed by the junction of the Fulda and the Werra. It is navigable for barges from the spot at which its name commences; and it receives, in its course, the Hamel, the Aller, the Oertze, the Leine, the Böhme, the Eyther, the Wümme, which in the lower part of its course takes the name of Lesum, the Geeste, and the Hunte; all of which are Hanoverian rivers, and continue their united courses till they are lost in the German Ocean near Bremen. *Third*, the Ems, a river rising in the Prussian province of Westphalia. After entering Hanover, it receives the waters of the Aa, the Hase, the Else, and the Leda. Before reaching the sea, it falls into the Dollart near Emden, which is the principal seaport in the kingdom. It is navigable for flat-bottomed vessels from Rheina downwards, and for sea-going ships from Halte and Weener. About 1,200,000 thalers (L.180,000 sterling) have been expended in improving the navigation, and it has become in consequence a very important channel for the inland trade of the country. *Fourth*, the Vecht, a river of short course, rising in the Prussian province of Westphalia, and terminating in the Zuyder Zee. Its principal importance is derived from a navigable canal, which commences at the city of Münster, and is the channel of some trade through the Vecht to Amsterdam.

Though Hanover is generally a sandy soil, it has some small fresh-water lakes. The Dummersee, in Diepholtz, is about 12 miles in circuit. The Steinhudermeer, in the province of Kalenburg, is about 4 miles long and 2 broad; and the Dollart, at the mouth of the Ems, which is rather an estuary than a lake, is 12 miles across. The canals are all of short course. The Aurich Canal, between Aurich and Emden, is 15 miles long; the Bremen

Canal, between the Oste and the Schwinge, serves both for draining and for transport; the Papenburg Canal, between Papenburg and the Ems, is unimportant.

The climate varies considerably with the nature of the country. In the low-lying districts near the coast it is moist and foggy, but the winters are not so severe as in the interior. Hurricanes are not unfrequent on the sea-coast during winter. In spring the prevailing winds are the N.E. and E., in summer the S.W. The mean annual temperature of the kingdom is about 46° Fahr.; at Lüneburg it is 48°; at Göttingen, 46°; but in the Harz district, only 43°. The average annual fall of rain is about 23·5 inches, but it varies greatly in different parts of the kingdom.

Though agriculture constitutes the most important branch of industry in the kingdom, it is still in a very backward state. The greater part of the soil is indeed of very inferior quality; but much that is susceptible of cultivation is still lying waste. The farms are generally very small, nearly one-half of them being under seven acres; while about three-fifths of the land is in the hands of small proprietors, comparatively few of whom possess the capital necessary for adequate cultivation. The best cultivated lands are those belonging to the crown, or nobility; and here considerable advances have recently been made. The best agriculture is to be found in the districts of Hildesheim, Kalenberg, Göttingen, Grabenhagen, on the banks of the Weser and Elbe, and in East Friesland and Bremen. In the hill country the three-field system prevails; but the low marsh lands have a system peculiar to themselves. The usual rotation is, first a fallow, on which the land is cultivated for potatoes, peas, or flax; then follows winter corn, either rye or wheat, but generally the former; and to these succeeds summer corn, either barley or oats. Of the entire area of the country about 28·98 per cent. is arable, 1·76 in gardens and orchards, 16·92 in meadow or pasture land, 13·88 in forests, 34·75 in heath, moor, &c., and 3·71 in roads, rivers, buildings, &c. Barley and oats are largely cultivated and exported in considerable quantities to England. Wheat is grown on the richer soils, but the quantity raised is not equal to the demand. Potatoes are universally cultivated, and constitute the chief food of the poorer classes. Rye is generally grown for bread. Flax, for which much of the soil is admirably adapted, is extensively cultivated, and forms an important article of export, chiefly, however, in the form of yarn. Hemp, tobacco, turnips, and hops are also among its products.

The rearing of cattle is extensively carried on. The number of horned cattle in Hanover is estimated at about 950,000, of horses at 300,000, and of sheep at 1,650,000. East Friesland is especially noted for its breeds of cattle and horses. Bees are reared very extensively in the heaths of Lüneburg. Large flocks of geese are kept in the moist situations; their flesh is salted for winter domestic consumption, and their feathers are preserved for sale.

Manufacturing industry prevails less in Hanover than in the other states of Germany. Linen yarn and cloth are the principal branches. Woollen cloths are made to a considerable extent in the southern part of the kingdom, and this branch of trade has lately been increasing. In the west, stockings and gloves are made. Cotton-spinning has also increased, but is still insignificant; and the same may be said of silk. Potteries, tile works, and tobacco-pipe works are numerous. There are nine glass-houses, and fifty-two paper-mills which produce yearly about 20,000 balls of paper. Wax is bleached to a considerable amount, and there are numerous tobacco factories, tanneries, breweries, vinegar works, and brandy distilleries, the produce of which last has of late very much increased. East Friesland produces gin. The most thriving branch of industry, however, is that of metal wares. The whole population of the Harz lives by the mining and forging of metals, excavating coal, and manufacturing wooden articles. Foundries and forges, and works of iron, copper, brass, wire, silver and lead, vitriol and sulphur, are in the utmost activity. These mines and associated works support about 35,000 persons. About 20,000 workmen were very recently employed in the Harz, and the yearly value of the produce was 5,000,000 thalers (L.750,000 sterling).

The latest returns give the following quantities for one year, for Hanover and Brunswick together:—Gold, 82 oz.; silver, 375,833 oz.; iron, 377,812 cwt.; copper, 540; vitriol, 5400; quicksilver, 540; coal, 2,160,000; salt, 842,000.

As may be supposed from the small quantity of surplus production, the trade of Hanover is not extensive. The principal port, Emden, has some export and import trade; but from the state of the roads between that place and the more populous parts of the kingdom, more of its trade passes through Hamburg and Bremen than through that city. Besides the more considerable articles made from flax, its honey, wax, feathers, and large quantities of timber, are sent to Hamburg and Bremen. Wool, horses, and cattle, wheat and other grain, butter and cheese, tobacco, and mineral productions, are among the chief exports. Hops, rape-seed, oil-cake, fruit, hams, and sausages, form also articles of export of small amount. The imports consist pincipally of English manufactures, colonial produce, fruits, wines, jewellery, and silks. As the roads to the great fairs of Leipsic and Frankfort pass through Hanover, the transit of goods for these used to create a pretty large commission trade, and give employment to many waggons, horses, and men, as well as to the barge owners. These, however, are now in some degree superseded by railways, the city of Hanover having become a central station, from which these diverge in different directions to Hamburg, Brunswick, Hildesheim, Bremen, and Minden. Hanover has joined the *Zollverein* or General Customs Union from 1st January 1854.

Hanover is a hereditary monarchy in the house of Guelph, with a salique law, which prevents the throne being filled by a female. In case the present branch becomes extinct, the heir of the duchy of Brunswick will succeed. In the several provinces that formerly composed the electorate, the provincial states were vested with functions much the same as those of the old States-General of France, and the central government communicated with these states separately. In 1814, when the territory was augmented, the same arrangement was extended to the newly acquired province. Various efforts were subsequently made to form a general constitutional government for the whole territory of the kingdom, resulting in what has been called the Constitution of 1819. Under this constitution the provincial states continued to subsist in their original forms, superintending the affairs of their several provinces; but there was superadded a States-General, divided into chambers—the first consisting of three princes, three counts, two Catholic bishops, three Protestant abbots, thirty-five deputies of the *Ritterschaft*, or higher landed gentry, the presidents of the board of taxes, and others; the second, of the deputies of the towns, universities, smaller landed proprietors, &c. This continued, with some alterations, till 1833, when it was superseded by a reformed constitution granted by King William I. At his decease, however, in 1837, this constitution was repudiated by his successor, King Ernest, who called an assembly of the States, as under the constitution of 1819. Under the pressure of the great movement of 1848, the Ritterschaft resigned their most important privileges, and were replaced in the upper chamber by the great funded proprietors; but under the subsequent re-action, the concessions then made by the crown have been partly recalled, and the constitutional question remains still undetermined. In 1851, the Federal Diet invited all the German governments to modify such of their fundamental laws as might seem calculated to foster revolutionary notions; and the government of Hanover has shown itself quite ready to follow out the spirit of the invitation. The Ritterschaft have been constantly endeavouring to recover their privileges, and have made applications for this purpose to the Federal Diet, which, in March 1855, resolved that, as the constitutional arrangements in the kingdom of Hanover were in many respects contrary to the fundamental federal laws, the Hanoverian government should be invited to bring its institutions into harmony with the federal system; and in case of obstacles arising to the required modifications, the Diet reserved to itself the power of interfering according to law. On 16th May 1855, the king issued an ordonnance in conformity with this resolution, making several modifications of the constitution, but reserving the power of carrying the order of the Diet more fully into effect. In December 1855 he abolished the right of trial by jury for political offences.

The sovereigns of Hanover were, like most others in Germany, the largest landed proprietors in their dominions. Their lands, however, royalties, and other branches of crown revenue, have been given up by the crown, and now form a branch of the general revenue of the kingdom. The budget for the year 1855–6 stood thus:—

RECEIPTS—From the Royal domains	L.247,592
... ... Imposts	767,280
... ... Forest and mines of the Upper Harz	7,239
... ... Lower Harz	6,598
... ... Coal-mines	6,515
... ... Salt-works	2,900
... ... Limestone of Lüneburg	2,895
... ... Tolls	48,299
... ... Posts	25,557
... ... Railways	133,208
... ... Tolls and pontage of the Board of Roads	30,116
... ... Lotteries	7,963
... ... Interest of active capital	17,401
... ... Other miscellaneous receipts	5,374
Total receipts	L.1,308,937
Total estimated expenditure	1,247,046
Surplus	L.61,891
Public debt at 16th January 1855	L.2,324,331
Railway debt	3,616,813
Total debt	L.5,941,144

Interest on debt...L.148,817, 13s. 2d.

The military establishment, consisting of the usual proportions of infantry, cavalry, artillery, and engineers, amounted altogether to 24,107 men.

The prevailing faith is Lutheran; the Lutherans in 1852 numbering 1,494,033 adherents. The Calvinists amounted to 95,220, chiefly in the provinces of Aurich and Osnabrück. The Roman Catholics are chiefly confined to the provinces of Osnabrück and Hildesheim, and amounted to 217,367. The Jews numbered 11,562, and other sects 1071. Education receives a considerable amount of attention, and is placed under a special board of direction. First among its educational institutions is the university of Göttingen, which is usually attended by about 700 students. (See GÖTTINGEN.) The other institutions are similar to those in the continental countries where education is best conducted, including primary and secondary schools, gymnasia, industrial, normal, and grammar schools. The scholars attending the various schools amount to about 220,000. There are also several medical, midwifery, and veterinary schools, and a school of mines and forestry at Clausthal. The charitable institutions are numerous.

HANOVER, the capital of the kingdom of the same name, is built on an extensive sandy plain on the Leine, which here receives the Ihme, and is from this point navigable to the Weser. The river flows through the town, dividing it into two parts, between which communication is maintained by several bridges. The old town, on the right bank of the river, is very irregularly built, and the streets are narrow, crooked, and dirty. The new town, on the opposite side of the river, is much superior in appearance, and contains several handsome streets. The walls surrounding the town, having become useless as a means of defence, were, in 1780, partly levelled and laid out in streets, and the remainder converted into a handsome esplanade. Outside the town are two suburbs, the Linden and the Gartengemeinde. The most interesting of the public buildings are the royal palace, with opera-house attached; the viceroy's palace; the house of assembly of the states; mint; arsenal; royal stables, with the famous breed of Hanoverian horses; the new theatre, built in 1851 of Italian architecture; and the town-hall and record office, containing a library of about 40,000 volumes, besides a valuable collection of MSS., chiefly given by Leibnitz. The Waterloo column, 162 feet high, surmounted by a figure of Victory, was erected in memory of the Hanoverians who fell at the battle of Waterloo. An open rotunda inclosing a marble bust has been erected in memory of Leibnitz. There are four Lutheran, one Roman Catholic, and three Calvinistic churches, and a Jewish synagogue. The educational institutions comprise the Georgianum (a college for educating sons of the nobility), a lyceum, a normal, a trade, and numerous elementary schools. Among the charitable institutions are an orphan asylum, blind asylum, almshouse, and several hospitals. The inhabitants derive their chief support from the presence of the court and nobility. Some manufactures are carried on, but chiefly on a small scale. The transit trade, however, is considerable—the town being connected by railway with Hamburg, Bremen, and Brunswick. In the vicinity are the royal palaces of Mont Brilliant, the summer residence of the present king, and Herrenhausen, with their famous gardens. Pop. (1852), including suburbs, 49,909.

HANOVER, a village of Grafton county, state of New Hampshire, North America. It stands on an elevated plain about half a mile E. of Connecticut River, and 55 miles N.W. of Concord. In connection with Dartmouth College, founded here in 1769, there is a flourishing medical school instituted in 1797. Among the eminent men who have been educated at Dartmouth College may be mentioned the late Daniel Webster. Pop. 2352.

HANSEATIC LEAGUE, the name given to an association, formed in the twelfth and thirteenth centuries, of the principal cities in the N. of Germany, Prussia, Poland, &c., for the better carrying on of commerce, and for their mutual safety and defence; and which contributed, in no ordinary degree, to introduce civilization and good government into the north.

Hamburg, founded by Charlemagne in the ninth century, and Lübeck, founded about the middle of the twelfth (1140), were the earliest members of the League. They early formed an intimate political union, partly with the view of maintaining a safe intercourse by land with each other, and partly for the protection of navigation from the pirates, with which every sea was at that time infested. There is no very distinct evidence as to the period when this alliance was consummated; some ascribe its origin to the year 1169, others to 1200, and others say 1241. But the most probable opinion seems to be, that it grew up by slow degrees, and was perfected according as the advantages derivable from it became more obvious. Such was the origin of the

Hanseatic League.

Hanseatic League, so called from the old Teutonic word *hansa*, signifying an association or confederacy.

From the beginning of the twelfth century, the progress of commerce and navigation in the north was exceedingly rapid. The countries which stretch along the Baltic from Holstein to Russia, and which had been occupied by barbarous tribes of Slavonic origin, were then subjugated by the kings of Denmark, the dukes of Saxony, and other princes. The greater part of the inhabitants being exterminated, their place was filled by German colonists, who founded the towns of Stralsund, Rostock, Wismar, &c. Prussia and Poland were afterwards subjugated by the Christian princes and the knights of the Teutonic order. So that, in a comparatively short period, the foundations of civilization and the arts were laid in countries whose barbarism had ever remained impervious to the Roman power.

The cities that were established along the coast of the Baltic, and even in the interior of the countries bordering upon it, eagerly joined the Hanseatic confederation; and previously to the end of the thirteenth century it embraced every considerable city in all those vast countries extending from Livonia to Holland, and was a match for the most powerful monarchs.

The Hanseatic confederacy was at its highest degree of power and splendour during the fourteenth and fifteenth centuries. It then comprised from 60 to 80 cities, which were distributed into four classes or circles. Lübeck was at the head of the first circle, Cologne of the second, Brunswick of the third, and Dantzic at the head of the fourth. The supreme authority of the League was vested in the deputies of the different towns assembled in congress. In it they discussed all their measures; decided upon the sum that each city should contribute to the common fund; and determined all questions relative to their common interests. The meeting of congress was most frequently held at Lübeck, which was considered as the capital of the League; but sometimes congresses were held at Hamburg, Cologne, and other towns. They met once every three years, or oftener if occasion required. Any one might be chosen for a deputy; and besides merchants, the congress comprised clergymen, lawyers, artists, &c. When the deliberations were concluded, the decrees were formally communicated to the magistrates of the cities at the head of each circle, by whom they were communicated to those below them; and the most vigorous measures were adopted for carrying them into effect. One of the burgomasters of Lübeck presided at the meetings of congress; and during the recess the magistrates of that city had the sole, or at all events the principal, direction of the affairs of the League.

Besides the towns already mentioned, there were others that were denominated confederated cities or allies. The latter neither contributed to the common fund of the League, nor sent deputies to congress. Even its members were not all on the same footing in respect to privileges—an arrangement that was a fruitful source of internal commotions.

As the power of the confederated cities increased, they began to aspire to the monopoly of the trade of the north, and to exercise the same dominion over the Baltic that the Venetians exercised over the Adriatic. For this purpose they succeeded in obtaining, partly in return for loans of money, and partly by force, various privileges and immunities from the northern sovereigns, which secured to them almost the whole foreign commerce of Scandinavia, Denmark, Prussia, Poland, Russia, &c. They repressed piracy by sea and robbery by land; introduced among the inhabitants conveniences and enjoyments unknown to their ancestors, and inspired them with a taste for literature and science; they did for the people round the Baltic what the Phœnicians had done in remoter ages for those around the Mediterranean, and deserve, equally with them, to be placed in the first rank among the benefactors of mankind.

Hanseatic League.

The kings of Denmark, Sweden, and Norway, were frequently engaged in hostilities with the Hanse towns; but their efforts to abolish the privileges the League had acquired in these countries served, for more than two centuries, only to augment and extend its influence.

"The astonishing prosperity of the confederated cities was not wholly the effect of commerce. To the undisciplined armies of the princes of the north, the cities opposed, besides the inferior nobles, whose services they liberally rewarded, citizens accustomed to danger, and resolved to defend their liberties and property. It was chiefly, however, on their marine forces that the cities depended. They employed their ships indifferently in war or commerce, so that their naval armaments were fitted out at comparatively small expense."[1]

The extirpation of piracy was one of the objects which had originally led to the formation of the League. Owing, however, to the barbarism then so universally prevalent, and the countenance openly given by many princes and nobles to those engaged in this infamous profession, it was not possible wholly to root it out. But the vigorous efforts of the League to abate the nuisance served to render the navigation of the North Sea and the Baltic comparatively secure, and were of signal advantage to commerce. Their exertions also to protect shipwrecked mariners from the atrocities to which they had been subject, and to procure the restitution of shipwrecked property to its legitimate owners, were in no ordinary degree meritorious; and contributed not less to the advancement of civilization than to the security of navigation.

To facilitate and extend their commercial transactions, the League established various factories in foreign countries; the principal of which were at Novogorod, London, Bruges, and Bergen.

Novogorod, situated at the confluence of the Volkof with the Imler Lake, was for a long period the most renowned emporium in the north-eastern parts of Europe. During the twelfth, thirteenth, and fourteenth centuries, it formed the *entrepôt* between the countries to the east of Poland and the Hanseatic cities. Its fairs were frequented by people from all the surrounding countries, as well as by numbers of merchants from the Hanse towns, who engrossed the greater part of its foreign trade, and furnished its markets with the products of distant countries.

But in the latter part of the fifteenth century, Ivan Vassilievitch, czar of Russia, asserted his right to the principality of Novogorod, and supported his pretensions by a formidable army. Having entered the city at the head of his troops, Ivan received from the citizens the charter of their liberties, which they either wanted courage or inclination to defend. But notwithstanding the despotism to which Novogorod was subject during the reigns of Ivan and his successors, it continued for a considerable period to be the largest, as well as most commercial, city in the Russian empire.

But the scourge of the destroyer soon after fell on this celebrated city. Ivan IV., having discovered, in 1570, a correspondence between some of the principal citizens and the king of Poland relative to a surrender of the city into his hands, took the most inhuman revenge. The crime of a few citizens was made a pretext for the massacre of 25,000 or 30,000. Though it never recovered from this blow, Novogorod continued to be a place of considerable trade until the foundation of Petersburg, which immediately became the seat of the commerce of which it had previously been the centre.

The merchants of the Hanse towns, or Hansards, as they were then commonly termed, were established in London at a very early period, and their factory was of considerable magnitude and importance. They enjoyed various privileges and immunities; they were permitted to govern themselves by their own laws and regulations; the custody of one of the gates of the city (Bishopsgate) was committed to their care; and the duties on various sorts of imported commodities were considerably reduced in their favour. These privileges naturally excited the ill-will and animosity of the English merchants; and the Hansards were every now and then accused of acting with bad faith, and obstructing the commerce of the English in the Baltic. The Hansards were in consequence exposed to many indignities; and their factory, which was situated in Thames Street, was not unfrequently attacked. The League exerted themselves vigorously in defence of their privileges; and having declared war against England, they succeeded in excluding our vessels from the Baltic, and acted with such energy, that Edward IV. was glad to come to an accommodation with them. In the treaty for this purpose, negotiated in 1474, the privileges of the merchants of the Hanse towns were renewed, and the king assigned to them, in absolute property, a large space of ground, with the buildings upon it, in Thames Street, denominated the Steel Yard, whence the Hanse merchants have been commonly denominated the Association of the Steel Yard. The property of their establishments at Boston and Lynn was also secured to them; and the king engaged to allow no stranger to participate in their privileges. One of the articles bore that the Hanse merchants should be no longer subject to the judges of the English Admiralty Court, but that a particular tribunal should be formed for the easy and speedy settlement of all disputes that might arise between them and the English. And it was further agreed that the particular privileges awarded to the Hanse merchants should be published as often as the latter judged proper, in all the seaport towns of England, and that such Englishmen as infringed upon them should be punished. In return for these concessions, the English acquired the liberty of freely trading in the Baltic, and especially in the port of Dantzic and in Prussia. In 1498, all direct commerce with the Netherlands being suspended, the trade fell into the hands of the Hanse merchants, whose commerce was in consequence very greatly extended. But, according as the spirit of commercial enterprise awakened in the nation, and as the benefits resulting from the prosecution of foreign trade came to be better known, the privileges of the Hanse merchants became more and more obnoxious. They were, in consequence, considerably modified in the reigns of Henry VII. and Henry VIII., and were at length wholly abolished in 1597.

---

[1] *L'Art de vérifier les Dates*, 3^{me} partie, tom. viii., p. 204.

The different individuals belonging to the factory in London, as well as those belonging to the other factories of the League, lived together at a common table, and were enjoined to observe the strictest celibacy. The direction of the factory in London was intrusted to an alderman, two assessors, and nine councillors. The latter were sent by the cities forming the different classes into which the League was divided. The League endeavoured at all times to promote as much as possible the employment of their own ships. In pursuance of this object, they went so far, in 1447, as to forbid the importation of English merchandise into the confederated cities, except by their own vessels. But a regulation of this sort could not be carried into full effect; and the irritation produced by the occasional attempts to act upon it, contributed materially to the subversion of the privileges which the Hanseatic merchants had acquired amongst us.

The principal factory of the League was at Bruges, which became, at a very early period, one of the first commercial cities of Europe, and the centre of the most extensive trade carried on to the north of Italy. The art of navigation in the thirteenth and fourteenth centuries was so imperfect, that a voyage from Italy to the Baltic and back again could not be performed in a single season; and hence, for the sake of their mutual convenience, the Italian and Hanseatic merchants determined on establishing a depôt or storehouse of their respective products in some intermediate situation. Bruges was fixed upon for this purpose, and, in consequence, speedily rose to the very highest rank among commercial cities. It was at once a staple for English wool; for the woollen and linen manufactures of the Netherlands; for the timber, hemp and flax, pitch and tar, tallow, corn, fish, ashes, &c., of the North; and for the spices and Indian commodities, as well as their domestic manufactures imported by the Italian merchants. The vivifying effects of this commerce were everywhere felt; the regular intercourse opened between the nations in the north and south of Europe made them sensible of their mutual wants, and gave a wonderful stimulus to the spirit of industry. This was particularly the case with regard to the Netherlands.

From the middle of the fifteenth century, the power of the confederacy, though still very formidable, began to decline. This was not owing to any misconduct on the part of its leaders, but to the progress of civilization, the general diffusion of the arts, and the establishment of the authority of government. In addition to these circumstances, the interests of the different cities of the League became daily more and more opposed to each other. Lübeck, Hamburg, Bremen, and the towns in their vicinity, were latterly the only ones that had any interest in its maintenance. When the Zealanders and Hollanders became sufficiently powerful at sea to be able to vindicate their right to the free navigation of the Baltic by force of arms, they immediately seceded from the League; and no sooner had the ships of the Dutch, the English, &c., begun to trade directly with the Polish and Prussian Hanse towns, than these also embraced the first opportunity of withdrawing from it. The fall of this great confederacy was really, therefore, a consequence of the improved state of society, and of the development of the commercial spirit in the different nations of Europe. It was most serviceable so long as those for whom its merchants acted as factors and carriers were too barbarous, too much occupied with other matters, or too destitute of the necessary capital and skill, to act in these capacities for themselves. When they were in a situation to do this, the functions of the Hanseatic merchants ceased as a matter of course; and at the middle of the seventeenth century the cities of Lübeck, Hamburg, and Bremen, were all that continued to acknowledge the authority of the League. They still, indeed, preserve the shadow of its power; being acknowledged in the act for the establishment of the Germanic confederation, done at Vienna in 1815, as free Hanseatic cities. (M'Culloch's *Treatises on Economical Policy*, 8vo. Edin. 1853.)

HANSY, a town of Hindustan, in the British district of Hurreeana, under the jurisdiction of the lieutenant-governor of the north-west provinces, situated on the edge of the canal cut from the River Jumna about the year 1353 by Sultan Feroz Shah, and restored by the British government in 1825. It is a very ancient town, and contains the tomb of a Mohammedan saint called Sheikh Jemmal. It was taken by the Mohammedans early in 1035, and has experienced many revolutions. Towards the end of the eighteenth century it was the capital of the short-lived principality erected by the adventurer George Thomas, which is now incorporated with the British dominions. Pop. of town, 9112; Lat. 29. 6., Long. 76. 3.

HANWAY, Jonas, a social reformer and philanthropist of the last century, was born in 1712 at Portsmouth. He served his apprenticeship to a merchant in Lisbon, and in 1743 became partner in an English firm in St Petersburg. His business led him to travel into Persia, and on his return he published *An Historical Account of the British*

Trade over the Caspian Sea, &c., in 4 vols. 4to—a work of no high literary aims, but of great practical use to the mercantile men of the day. The work had great success; and Hanway, encouraged by the result, continued for the remainder of his life to use his pen, though chiefly for the sake of the many charitable and philanthropic schemes which he either set on foot himself or took a strong interest in. He founded the Marine Society and the Magdalen Charity, both still in existence, and in their respective spheres doing much good; and strenuously promoted the Sunday-schools, then in their infancy. His great services were at length to meet their reward. In 1762 a deputation from leading merchants of London was successful in obtaining for him from government a commissionership of the navy. The name of Hanway often occurs in the social history of these times. He was a handsome man, and knew that he was so; indeed at St Petersburg he used to be called "Le bel Anglais." He took great care of his person, and on one occasion became the talk of the town for carrying about an umbrella with him; and as that curious engine did not come into vogue till about thirty years later, its first supporter had much ridicule and banter to encounter. His whims on the subject of tea are well known. Hanway died September 5, 1785.

HARBOURS

ARE either natural or artificial. Some parts of the British coasts are amply provided with natural bays and creeks, while in other parts the accommodation and shelter for shipping have been entirely supplied by artificial means. Thus, Ireland and the west coast of Scotland are plentifully intersected by excellent deep water bays and anchorages; but on the east and south-west shores of Britain there are but few natural harbours. Cromarty Bay is 200 miles distant from the Firth of Forth, which is the nearest southern natural harbour; while there are no less than 400 miles between the Firth of Forth and the Thames, which may be considered as the next really unexceptionable harbour of refuge. On the west coast there are about 200 miles of coast between the nearest natural harbours of Holyhead and Loch Ryan. The construction of artificial places of refuge becomes therefore a very important matter in a country where every winter's lists of shipwrecks and loss of life, remind us how much nature has left for art to accomplish. For the most complete body of evidence regarding the ports of Britain, we cannot do better than refer to the volumes of Reports by the Tidal Harbour's Commission, for the completeness of which the public is mainly indebted to the zeal of Captain Washington, the present indefatigable Hydrographer to the Admiralty.

The designing of harbours constitutes confessedly one of the most difficult branches of civil engineering. In making such designs, the engineer, in order to avail himself of the advantage which is to be derived from past experience, must endeavour to the best of his power to institute a comparison between the given locality and some other, which he supposes to be in *pari casu*. Perfect identity, however, in the physical peculiarities of different stations, seldom if ever exists, and all that can be done is to select an existing harbour, which appears to be as nearly as possible similarly circumstanced to the proposed work.

Force of waves.

In considering the subject of the construction of harbours in exposed situations, the first and most important subject deserving our attention is the destructive action of the element with which we have to deal,—what are its energies when excited by storms, and what the direction of its forces on the barriers which have been raised to control it?

Smeaton, in his history of the Eddystone, when speaking of the objection that might be raised against the necessity for using joggles in the masonry of that building, says, "When we have to do with, and to endeavour to control *those powers of nature that are subject to no calculation*, I trust it will be deemed prudent not to omit in such a case anything that can without difficulty be applied, and that would be likely to add to the security." This statement of our greatest marine engineer, indicates the propriety of carefully collecting any facts that may help us to a more accurate estimation of those forces which he regarded as being "subject to no calculation." We shall therefore state a few facts which have been recorded of the destructive power of the waves in inland lakes, and in the open ocean.

The writer has seen at Port Sonachan, in Loch Awe, where the fetch is under 14 miles, a stone weighing a quarter of a ton, torn out of the masonry of the landing slip and overturned. Mr D. Stevenson, in his *Engineering of North America*, describes the harbours in Lake Erie as reminding him of those on our own sea-girt shores, and mentions having seen one stone weighing upwards of half a ton which had been taken out of its bed in the pier at Buffalo, moved several feet and overturned. The Comte de Marsilli, in his *Histoire Physique de la Mer*, published at Amsterdam in 1725, states that the highest wave observed by him on the shores of Languedoc in the Mediterranean Sea, where the breadth is about 600 miles, was 14 feet 10 inches. At the mouth of a harbour on the German Ocean, with a fetch of about 600 miles, the writer had observed for him the height of the waves during south-easterly gales, and on one occasion the result was $13\frac{1}{2}$ feet from the crest of the wave to the trough of the sea. In deeper water, and with a north-easterly gale there is no doubt that the waves of the German Ocean will attain a height considerably greater than this. In November 1817 the waves of the German Ocean overturned, just after it had been finished, a column of freestone 36 feet high and 17 feet base. The diameter at the place of fracture was about 11 feet. In the Atlantic Ocean, Dr Scoresby stated, in a communication to the British Association in 1850, that during several hard gales he had measured many waves of about 30 feet, but the highest was 43 feet from the hollow to the crest. Waves of such magnitude could scarcely, however, reach our artificial harbours from the shallowness of the water near the shore. To these facts it may be added, that we know (from the testimony of an eye-witness) of a block of 50 tons weight being moved by the sea at Barrahead, one of the Hebrides; and what is far more extraordinary, we know, and can vouch for the fact, that blocks of 9 tons weight have been quarried, or broken out of their beds *in situ*, on the top of the Bound Skerry of Whalsey in Zetland, which is elevated 85 feet above the level of the sea. The Bound Skerry and neighbouring rocks, which are in the German Ocean, certainly furnish by far the most wonderful proof that has yet been discovered, of the great force which is developed by the billows of the ocean when suddenly checked by opposing rocks.

The writer has stated (in the *Trans. Roy. Soc. Edinburgh*) that, from the observations which he had made with the marine dynamometer (a self-registering instrument designed by him for the purpose), he had found the force of the waves of the *German* Ocean during hard gales, to be $1\frac{1}{2}$ *ton per superficial foot* at the Bell Rock, and of the Atlantic Ocean to be 3 *tons per superficial foot* at the Skerryvore Lighthouse. But these results may still be far short of the maxima. As the marine dynamometer has been often found useful in indicating the force of the waves in situations where harbours were to be built, it may be proper to give such a description of it as will enable any one to have it made.

DEFD is a cast-iron cylinder, which is firmly bolted at the projecting flanges G, to the rock where the experiments are to be made. This cylinder has a circular flange at D. L is a door which is opened when the observation is to be read off. A is a circular disc on which the waves impinge. Fastened to the disc are four guide rods B, which pass through a circular plate C, which is screwed down to the flange D, and also through holes in the bottom EF. Within the cylinder there is attached to the plate C a powerful steel spring, to the other or free end of which is fastened the small circular plate K, which again is secured to the guide rods B. There are also rings of leather, T, which slide on the guide rods and serve as indices for registering how far the rods have been pushed through the holes in the bottom, or, in other words, how far the spring has been drawn out by the action of the waves against the disc A.

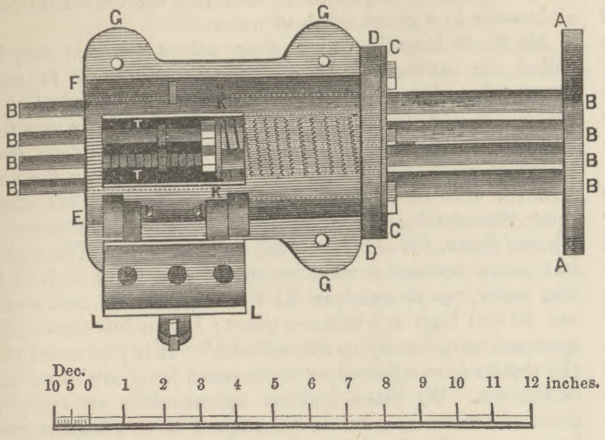

Fig. 1.

Line of maximum exposure.

In comparing an existing harbour with a proposed one, in order to ascertain the dimensions which are necessary to insure stability, perhaps the most obvious element is what may be termed the *line of maximum exposure*, or, in other words, the line of greatest *fetch* or *reach* of open sea, which can be easily measured from a chart. But though possessed of this information, the engineer still does not know in what ratio the height of the wave increases in relation to any given increase in the line of exposure.

As this inquiry is one of great moment in the practice of marine engineering, and has not been in any way investigated, the writer has for some time back been making occasional observations on the subject, when favourable circumstances occurred. These observations have been but limited in extent, and cannot be regarded as deserving of confidence unless in cases where the two harbours are not far different in their lines of exposure. So far as these experiments have gone, the waves seem to increase in height most nearly *in the ratio of the square root of their distances from the windward shore*.

It does not follow, however, that the line of maximum exposure is in every case the line of maximum effective force of the waves; for this must depend not only on the length of *reach*, but also on the angle of incidence of the waves on the walls of the harbour. What may be termed the line of *maximum effective exposure* is that which, after being corrected for obliquity of impact of the waves, produces the maximum result, and this can only be taken from the chart after successive trials. Let $x =$ the greatest force that can assail a pier, $h =$ height of waves which produce (after being corrected for obliquity) the maximum effect, and which are due to the line of maximum effective exposure. Sin $\alpha =$ sine of azimuthal angle formed between directions of pier and line of maximum effective exposure, radius being unity. Then $x \propto h \sin^2 \alpha$ when the force is resolved normal to the line of the pier; but if the force is resolved again in the direction of the waves themselves, the expression becomes $x \propto h \sin^3 \alpha$.*

It should not be forgotten, in connection with this subject, that there are various qualifying elements to which special attention requires in some cases to be given. The waves, for example, may often be noticed, when approaching the land obliquely, to alter their direction when they get close to the shore (in consequence of the depth changing), so as to strike it more nearly at right angles to the general line of the beach. In this way a swell from the ocean may enter a bay which is not directly exposed to it. It should also be observed, that the lines of exposure cannot be directly compared if the depths of the water through which they pass are materially different.

Effect of the tides.

The tides, too, exert in many places a very decided effect on the nature of the billows, in some places causing waves of an unusually dangerous character, while at others they are found to *run down* the sea. If a marine work is situated in a *race* or rapid tide-way, such, for example, as those called "roosts" in Orkney and Shetland, the masonry will be exposed to the action of a very trying and dangerous high-cresting sea. As an example of this, we may refer to Port-Patrick in Wigtonshire, where the violence of the waves is, we have no doubt, much due to the rapidity of the tides. If, on the other hand, the race or roost runs in such a direction as to be entirely outside of the harbour, and at some distance off, it will have a decided tendency to shelter the works, and to act as a breakwater. Thus it appears, from observations specially made for the writer at Sumburgh Head Lighthouse in Shetland during a south-westerly storm, that so long as the Sumburgh roost (one of the most formidable in those seas) was cresting and breaking heavily, one could have easily landed in a small boat at a creek or bay called the West Voe; but no sooner did the roost disappear towards high water than there came in towering billows that totally submerged cliffs of very considerable height. The study of the modifying and intensifying effects of tide-currents on the waves of our British seas seems to have been entirely neglected in the late discussions regarding the merits of vertical and sloping walls, which will be referred to in another section of this article.

We think it right to mention that we consider as erroneous the opinion expressed by a writer in the *Edinburgh Philosophical Journal*—that the cause of races or roosts is the meeting of two rapid currents; neither do we believe that they are occasioned by the projection of rocks from the bottom of the sea as many sailors suppose.

From careful inquiries, as well as from actual personal experience, of such formidable breaking waters as the Boar of Duncansbay, and the Merry Men of Mey in the Pentland Firth, and several others, we are of opinion that the true cause is the *swell of the sea encountering a tidal current running in a direction more or less opposed to that of the waves.* While it is obvious that two rapid tides may meet each other without any dangerous effects, it is also quite true that when two tides meet each other in a rough sea, as in coming round such islands as Stroma or Swona in the Pentland Firth, the effect of their union being to increase the current at that place, there will be produced a highly dangerous sea; but the fact of their meeting, though calculated to aggravate, is not, we think, the primary cause. The races which occur in open seas, as, for instance, off headlands and turning-points of the coast, are certain portions of those seas in which the waves *break* to a greater or less extent, although the water may be very deep, and there may be no wind at the time. At all such places it will be found that there are rapid tides. The roosts on the west coast of Orkney or of the Pentland Firth, for example, are worst with *ebb* tides and *westerly* swells, because the Atlantic swell and current of ebb are opposed. Those again on the east coast are worst with *flood* tides and *easterly* swells from a similar cause. Thus at the east end of the Pentland Firth the Boar of Duncansbay is well known to rage with easterly swells and a flood tide; whereas, at the west end of the same firth, the Merry Men of Mey are equally well known to be worst with ebb tide and a westerly swell, at which time no boat could enter them without the risk of being overturned. The dangerous surf which exists at the mouths of some rivers is, we believe, not solely due to the want of depth at the bar, but also to the meeting of the outward current with the waves of the sea.

---

* For experimental results *vide* article HYDRODYNAMICS.

When a swell encounters a rapid opposing current, the onward motion of the waves seems to be arrested, and their width becomes visibly decreased. They get higher and steeper, crest, and at last break, sometimes very partially, and at other times almost as they would on a shelving beach. It appears to us possible that several waves may ultimately combine in such disturbed waters into one mountainous billow; for the wave that has partially broken may have its onward motion so much checked as to allow the wave behind to overtake it, and having thus coalesced, they may, as one large wave, acquire a superior velocity, so as to overtake those in front, and be farther augmented by the union of other waves which have been reflected from the shore.

It is to this cause we are inclined to refer such wonderful effects as that to which we have already alluded, where blocks of 9 tons weight were quarried out of the solid rock at an elevation of 85 feet above the sea. Were such violent action common to all the shores of the German Ocean, instead of being restricted to one or two similar places, half of our eastern seaport towns would, without any doubt, be washed into the sea during the first stormy winter. As a further proof of the great effect of the tides in exasperating the waves, we may mention that the time when most damage is done to seaworks which are in tolerably deep water, is from one to two hours before and after high water, which nearly corresponds to the time when the tide runs strongest outside. We have found this to hold true at many different parts of the coast, but will only refer to one well-marked instance. At Peterhead harbour, which projects prominently into the sea on an isthmus, the tides, at but a short distance seaward of the harbour, run very rapidly. On the 10th January 1849 there was a very heavy sea, and a crowd of people were down, about *two hours before high water*, helping to secure the whalers and other vessels in the harbour, when three successive waves carried away 315 feet of a bulwark, founded 9½ feet above high-water springs, which had stood for many years. One piece of this wall, weighing 13 tons, was moved 50 feet. After this outbreak of the sea the waves became more moderate, until about *two hours after high water*, by which time the large whalers had taken the ground, when other three enormous waves again swept over the harbour, submerging the quays to the depth of from 6 to 7 feet of solid water, by which sixteen people were drowned. These waves filled the harbour to such a depth as to set all the whalers afloat again, and they continued so for several minutes, until the excess of water had run out through the harbour mouth.

These gigantic waves were, in our opinion, clearly the result of some such action as has been attempted to be described. We should not have dwelt at such length on this subject were it not that we might again refer to the facts when we come to treat of the subject of vertical and sloping walls for harbours of refuge, where it is of importance to show that even in the deepest water, the waves are not purely oscillatory, but that wherever there is a tide-way the waves will more or less partake of the qualities of waves of translation.

Relation between height of waves and depth of water.

Another circumstance affecting the exposure of any marine work is the depth of water in front of it. The great mountainous billows so commonly met with in the Atlantic Ocean cannot be generated in the shallower waters of the German Ocean, unless perhaps in such peculiar circumstances as have just been adverted to. It becomes, therefore, of great consequence to ascertain the maximum possible wave in a given depth of water.

Mr Scott Russell, whose observations on what may be called the marine branch of hydrodynamics are of such great value, has stated that if waves be propagated in a channel whose depth diminishes uniformly, the waves will break when their height above the surface of the level fluid becomes equal to the depth at the bottom below the surface (p. 425 *Brit. Assoc. Rep. on Waves*). This statement, the meaning of which seems doubtful, Mr Russell elsewhere (*Instit. Civ. Eng.*, p. 136) defines thus: "The author has never noticed a wave so much as 10 feet high in 10 feet water, nor so much as 20 feet high in 20 feet water, nor 30 feet high in 5 fathoms water; but he has seen waves approach very nearly to those limits." It is presumed that the datum here referred to is the mean level of the surface of the sea. We have had no opportunities of verifying these observations; but as the subject is very important—because the depth of water in front of a work may be said to be the ruling element which determines the amount of force which it has to resist, whatever be the line of maximum exposure, we shall simply state what has come within our own knowledge and observation. We have repeatedly seen at different parts of the coast breaking waves of from 4 to 5 feet, measuring from hollow to crest, in from 7 feet 8 inches to 10 or 11 feet of water, measuring from the bottom up to the mean level; and on one occasion we were told of waves which were estimated at 9½ feet in 13 feet water. It must, however, be borne in mind that these observations, and we conceive also those of Mr Russell, apply only to common waves of the sea, or those short, steep, and superficial waves which are due to an existing wind, and not to the ground swells which are almost constantly to be found in the open ocean, and which may be the result of former gales, or are the telegraph, as Mr Russell terms them, of those which are yet to come.

From what has been stated, it would appear that in most cases the heaviest waves should assail any tide-work at high water. This, however, as mentioned in the last section, is not always the case, the greatest damage being often found to occur at the time when the tide runs strongest.

Mr Leslie found that the Arbroath Harbour-works were in general less severely tried by the very heaviest waves than by a class of waves somewhat smaller than these, owing to the outlying rocks, which, from the small depth over them, had the effect of *tripping* up the heavier seas, and thus destroying them before they reached the harbour, while the depth was sufficient to allow the smaller waves to pass over the shoals unbroken. In some cases of severe exposure the waves might to some extent be reduced by dropping very large stones outside of the harbour, so as, by forming an artificial shoal, to cause them to crest and break.

One great difficulty connected with the subject of the generation of waves still remains unsolved, viz.,—What are the minimum line of exposure and area of sea which are compatible with the existence of a ground swell? This question, we fear, cannot be answered in the present state of our knowledge.

Deep Water Harbours.

Profile of breakwater for harbours of refuge.

Harbours of refuge are distinguished from tidal harbours mainly by the superior depth of water which they possess, and the larger area which they inclose. The requisites are shelter during storms, and easy access for shipping at any time of tide. There has been much discussion as to whether piers for harbours of refuge should be *vertical* or *sloping*. Col. Jones, R.E., has especially advocated the superior merits of the vertical wall; and the discussions on his plan at the Institution of Civil Engineers, and the able protest by Sir Howard Douglas, will be found, from their interest and importance, to merit a careful perusal.

The principle which is asserted is, that oceanic waves in deep water are purely oscillatory, and would occasion no impact against vertical barriers, which would be the most eligible, as they would only have to encounter the simple hydrostatic pressure due to the height of the advancing billow, and would reflect the waves without causing them to break.

Were it even admitted that the waves were purely oscillatory, and were reflected by a vertical barrier, would no force, it may be asked, be expended when the motion of the particles was reversed? The reflection of a wave is equivalent to the nearly instantaneous creation of a wave in the opposite direction, for which a very considerable force must surely be required.

We believe, however, that from the effect of tide currents, to which we have already referred, and perhaps from other causes whose action seems to have been overlooked by the advocates of the upright wall, any form of barrier, in whatever depth it may have been erected, must be occasionally subjected to heavy impact. We conceive that the possibility of waves of translation being generated in the deepest water has been already established, if we succeeded in satisfying the reader of the truth of the following assertions:—*First*, That waves break in deep water during calm weather; a fact which is apparent to the eye and familiar to all sailors: and, *secondly*, and negatively, That to leeward of those races or portions of broken water, which certainly do not reflect the incoming waves, there is comparatively smooth water both at sea and on the adjoining shores, until such time as the strength of the tide is exhausted, and the roost has disappeared, when violent action is again fully manifested.

It may be argued that these are extreme cases, and that such high velocities in the current of the tide are seldom met with. This objection has, no doubt, truth in it; but still the tendency is shown, and though the velocities may be less in other quarters, there may yet be quite enough to destroy the condition of *stagnation* which the oscillatory theory assumes. The breaking of waves at sea, and the existence of races, seem to prove beyond question that waves of translation are possible in the deepest water. Is it not also a probable case that waves which have been reflected by a vertical wall, and have (irrespective of the question of tide currents) combined with the advancing waves, may then become waves of translation, possessing all the elements which endanger the stability of a sea work? Or, again, how much more damage would result to a vertical wall than to a slope of loose stones, from the sinking of the foundations, or from their getting underwashed by the reaction of the waves? It therefore appears that the method generally resorted to of forming deep water harbours of masses of rubble stone with long slopes, so as to form an artificial beach for the waves to spend on, is, in most circumstances, the best and cheapest kind of construction. We incline, however, to the adoption of an upright wall, founded on the rubble as a basis (similar to that at Cherbourg, about to be described), in preference to long paved slopes, as there is always experienced a great difficulty in founding the toe of such talus walls among the loose rubble. When pitched slopes are adopted, great benefit will be found to accrue from leaving at the bottom or toe of the slope a wide foreshore. Much, however, depends on local peculiarities in selecting the best design for any work; and the nature of the bottom is all-important. Where the bottom is soft, a vertical wall can hardly, if ever, be attempted.

In making these remarks, we must not be understood as condemning the adoption of vertical walls in cases where the foundation is good. All that we assert is the opinion, that waves of translation do exist in deep water, and therefore that harbours of refuge will prove failures unless they are built in such a manner as to resist the impact of those waves of translation. The Cherbourg breakwater has been often referred to as a successful instance of the application of a vertical wall, and has been contrasted with the Plymouth breakwater, which has a long slope. But this appeal is quite fallacious, as the profile of that work is, as already hinted, of a composite character, consisting of a talus wall sloping at the rate of 10 horizontal to 1 perpendicular, surmounted by a plumb wall; so that whatever merit may be supposed to belong to the vertical profile is entirely nullified at Cherbourg by the long talus wall in front, on which the violence of the waves is much broken. Moreover, the heaviest waves at Cherbourg come from the N.W., and do not assail the breakwater at right angles to its direction, but come more nearly *end on* to the work, so as to a great extent to run along the outer wall. The N.W. waves are propagated from the Atlantic, while the waves which are most trying to the work come from the N., in which direction the line of exposure is only about 21 leagues. These facts we obtained during a recent visit to Cherbourg, undertaken for the special purpose of ascertaining the physical characteristics of the place. The attempt to make out a parallelism between Plymouth, which faces the Atlantic directly, and Cherbourg, which is comparatively land-locked, cannot, in our opinion, stand the test of a candid inquiry.

Other comparisons may be referred to which have been advanced on equally untenable grounds. Thus, the old pier of Dunleary, which is vertical, and has stood well, has been compared with the talus walls of Kingstown Harbour, which now protect Dunleary, and which have often received much damage. The all-important element of depth of water has been in this instance entirely overlooked; for at Kingstown there is a depth of 27 feet, while Dunleary is all but dry. An able writer on the same *questio vexata*, in comparing different sea walls in the Firth of Forth, has, in like manner, not sufficiently adverted to the great differences in the depths opposite the works to which he refers.

An important advantage of the sloping wall is the small resistance which it offers to the impinging wave, but it should also be borne in mind that the weight resting on the face stones in a talus wall is decreased in proportion to the sine of the angle of the slope. If we suppose the waves which assail a sloping wall to act in the horizontal plane, their direct impulse, when resolved into the force acting at right angles to the sloping surface of the talus wall, will be proportional to the sine of the angle of incidence. The effective force when estimated in the horizontal plane, will be proportional to the square of the sine of the angle of incidence. But if we assume the motion of the impinging particles to be horizontal, the number of them which will be intercepted by the sloping surface will be also reduced in the ratio of the sine of the angle of incidence, or of elevation of the talus wall. Hence the tendency of the waves to produce horizontal displacement of the wall, on the assumption that the direction of the impinging particles is horizontal, will be proportional to the cube of the sine of angle of elevation of the wall.

If it farther happens that there is obliquity of action in the azimuthal as well as in the vertical plane arising from the relative direction of the pier and of the waves, there will be another similar reduction in the ratio of the squares or cubes of the angle of incidence according as the force is resolved into that at right angles to the line of the pier, or to that of the direction of the waves.

Let ϕ = vertical angle of incidence or angle of elevation of wall;

ϕ' = azimuthal angle of incidence;

f = horizontal force exerted on unit of surface at right angles to the line of harbour wall;

h = height of greatest assailing waves;

$$f \propto h\,(\sin\phi \sin\phi')^3.$$

Harbours.

The above expression assigns, we think, too great a reduction, as the motion of the particles may not be horizontal, and no account is taken of the effects of friction against the rough surface of the masonry. Experiments are therefore wanting to determine the constant for correcting the theoretical results due to this expression. For further information on this subject, we refer the reader to the article on HYDRODYNAMICS.

Parabolic profile.

Mr Scott Russell recommends the parabolic curve as that best suited for the profile where the object is to *break* the waves, and not to reflect them, as is the case in sloping breakwaters. This curve possesses, according to Mr Russell, the advantages of superior strength, of economy in the materials, of breaking the wave early, and of continuing an uniform action over the longest period of time. When the tide is low, the toe of the slope, which springs out of the *foreshore* and forms the vertex of the parabola, would, we fear, be found rather weak, and perhaps difficult to form. On the whole, we rather incline in such cases simply to throw in the materials, and to allow the sea to form its own slope.

According to Sir John Rennie (*Account of Plymouth Breakwater*), rubble breakwaters with slopes formed at the angle of repose, were adopted by the Greeks in the moles of Tyre and Carthage, and by the Romans at Athens and Halicarnassus. The same design was also followed at Venice, Genoa, Rochelle, Barcelona, and other places. In this kingdom the first example on a large scale which we find is at Howth. Kingstown, Holyhead, and the noble breakwater at Plymouth, were afterwards carried out on the same principle, and chiefly under the directions of the late Mr Rennie. The great national harbours of refuge at present in progress in this country, according to Mr Rendel's designs, at Holyhead and Portland, are on a similar principle; while those under Messrs Walker, Burgess, & Cooper, at Dover, Alderney, and Jersey, are more nearly vertical.

On the best Forms of Walls for Tidal Harbours.

Having now considered the few facts of which we are in possession regarding the disputed nature of the impulse of the waves in deep waters, we shall direct the reader's attention to their effects in shallow water. Those in deep water were chiefly *whole waves*, and regarded by many as being purely oscillatory, while those in shoal waters are breaking waves, and therefore regarded by all as waves of translation. We have hitherto been considering breakwaters erected in deep water, and which were constantly exposed to the waves; we now turn to piers and sea-walls which are placed within the range of the surf, and which are exposed to its force for a limited period only, being sometimes left nearly, or altogether dry by the receding tide.

The impulse of the waves against a sea-wall or pier may be resolved practically into four directions:—1st, The direct horizontal force which tends to shake loose, or carry before it, the blocks of which the opposing masonry consists. This force may also blow up the pitching, or overturn the inner or quay-wall by condensing the air, or pressing upon the water which occupies the interstices of the rubble. We know two cases in the German Ocean where, in consequence of want of width in the pier, coupled, in one instance, with insufficient workmanship, the inner or quay-walls were observed first to bulge and fall, before the sea-wall was injured. One of these piers measured 26 ft. 4 in., and the other 24 ft., on the roadway. 2d, The vertical upward force which may act on any projecting stone or protuberance. 3d, The vertical downward force of the water which results either from the wave breaking upon the toe of a talus wall, or from the wave passing over the parapet, and falling upon the pitching behind, so as to plough it up. 4th, The *back-draught* which tends by reaction from the wall to plough up the soft bottom, and thus to undermine the lower courses of the work, or perhaps by *suction* to pull out the facework. We may conclude from the above that the points which require to be carefully attended to are—1st, The contour and quality of masonry of the wall itself; 2d, The parapet, which, if not of sufficient height, or built in a proper direction, leads to damage in the pitching behind it; and 3d, The foundation-courses, in the design and construction of which, if similar precautions be not attended to, underwashing of the bottom may in some situations take place, so as to leave the lowest courses without protection.

Harbours.

Buildings on a rock foundation.

We shall in the first place consider how far those remarks are applicable where the bottom is solid rock. Such a supposition will render unnecessary any precautions arising from the wasting of the bottom, and, *cæteris paribus*, there does not seem to be any reason for preferring a talus to a vertical wall. The question of preference in such a case will in the main depend upon the kind of material which can be obtained. Should the stone be scarce or costly, and the quality such as to warrant the introduction of masonry of the best description, the vertical wall may be found to be the most economical. Where freestone is to be used, it is not only desirable that it should be got in large blocks, but that the face stones should possess considerable hardness. This precaution is particularly necessary in selecting the stones for the lower courses, and especially where the beach consists of hard gravel. For the same reason, it is highly important that all stones which are subject to decay from atmospheric influence should be either entirely rejected or assembled in the upper courses of the parapet.

Where the materials are abundant, but of an unworkable nature, a long talus wall will generally be found most economical. For such walls the rate of slope must depend very much upon the exposure of the place, and upon the plentifulness of rubble-stone hearting. The easily-dressed and naturally flat-bedded materials, which the stratified rocks of the secondary formation very often furnish, are especially applicable for the construction of vertical walls; while the uncouth blocks of the primary and igneous formations are better suited for talus walls. Such rocks as gniess, the schists, basalts, greenstones, amygdaloids, and the tougher kinds of granite, are best fitted for this purpose. With some of those rocks the angularity of the pieces, and the excessive difficulty of dressing, render it necessary to assemble them without almost any alteration of their shape, by an adaptation of their salient and re-entrant angles, so as to make a kind of random rubble face-work. In this kind of work, mortar is very seldom employed. The parapet generally consists of squared masonry, surmounted by a heavy cope, and it should in every case be set in good lime mortar.

Where the materials are light and of small sizes it is desirable to equalize the action of the sea over the whole work, and not to concentrate it against any particular place. Mr Russell states that the cycloidal form was recommended for this purpose by Franz Gerstner of Bohemia. The only instance with which we are acquainted of the adoption of this curve was in a sea-wall erected at Trinity, near Edinburgh, by the late Mr Robert Stevenson, in 1822.

Buildings on soft or sandy foundations.

It has been already stated that, irrespective of the quality of the masonry, the two points in the structure which are weak or dangerous are the top and bottom of the wall. With a rocky bottom the risk of failure at the foundations is removed; on the other hand, where the shore consists of rotten rock, moving shingle or sand, it is obvious that provision must be made for both those sources of evil. In fact, if we consult the history of harbours, we shall find that by far the most frequent cause of damage is the reaction of the sea against the shore.

The general slope of a fragmentary beach must depend upon the size and nature of the particles and the force of the sea. The dissimilarity between the slopes of a beach near the levels of high and low water, arises from a decrease in the force of the waves, owing to their being broken before they reach the high-water mark. The great object, therefore, is to design the profile of our wall so as to alter as little as possible the symmetry of the beach. Where isolated rocks or large boulders are seen projecting above the surface of a sandy beach, there will generally be formed around them hollows, corresponding in depth to the kind of obstruction which the rocks present. The principal point in the design, therefore, must be to avoid great and sudden obstructions to the movement of the water. The best form which could be adopted in any situation would of course be the same as the cross section of the beach itself, but this would answer no possible purpose; and, as the wall is to consist of heavy blocks of stone instead of minute particles of sand, it is clear that a much steeper slope may be adopted than *the profile of conservancy* of the coast, provided the lower part of the slope be flattened out so as to meet the sand at a low angle. The action of a bulwark is to arrest the waves before they reach the general high water mark, and to change the horizontal motion of the fluid particles to the vertical plane, or to compel the waves to destroy themselves on an artificial beach consisting of heavy stones. To prevent underwashing, the two following requisites should therefore be as far as possible secured:—1st, The foundation courses or bottom of the wall should rise at a very small angle with the beach, so that their top surfaces may be coincident with the profile of conservation of that portion of the beach out of which the wall springs; 2d, The outline of the wall should be such as to allow the wave to pass onwards without any sudden check till it shall have reached the strongest part of the wall, which should be as far from the foundation as possible.

Those two requisites show clearly how inapplicable a vertical wall must in most cases be for a sandy beach. Instead of altering the direction of the wave at a distance from its foundation, the whole change is produced at that very point, and unless the wall be founded at a great depth, its destruction is all but certain. Where the materials are costly, but admit of being easily dressed, we are disposed to think that horizontal, or nearly horizontal wall connected with a vertical one by a quadrant of a circle may be found suitable. Such a form will prevent to a considerable extent the danger of reaction by causing an alteration in the form of the wave at that part where the wall is strongest and at the greatest distance from the toe or curb course. Where the materials are abundant and of a rougher nature, a cycloidal wall, with vertical and horizontal tangents somewhat similar to that erected at Trinity, to which we have already referred, may be adopted with advantage.

Foundations in clay.

A special caution may not be out of place regarding clayey bottoms. Many are apt to suppose that there can be no better foundation than clay; and it is indeed true that some kinds of hard clay form a satisfactory subsoil. But there are others of a softer kind, and permeated by sandy beds, which are extremely treacherous. If there be the slightest dip seawards, there is always a risk of any pier that may be built on such a base slipping bodily into the sea. This holds especially true of inland lochs, where the sides very often slope suddenly. In one instance, the particulars of which we got on the spot shortly after the accident, a pier built on a clayey beach, sloping below low water at the rate of 1 in 12½, suddenly began to move, and after two hours it had slipped seawards 150 feet, and had by that time descended bodily a height of 34 feet, the top of the pier being then no less than 23 feet below low-water spring tides.

Construction of Harbours.

Our space will not admit of our going much farther into the subject of the construction of harbours than the few remarks we have already made. A knowledge of such matters may to some extent be acquired by a careful perusal of the published histories of marine works; but, after all, it must be confessed that the only valuable teacher in this wide practical field is *experience*. It is, in truth, impossible to lay down any general rules of guidance as to matters of this kind. All that can be done within our space is to notice very briefly some of the more important methods of working. And first, with regard to that invaluable piece of apparatus, the diving-bell, we would refer to the article on the subject in this work, and to Smeaton's *Account of Ramsgate Harbour*, published in 1721, where it was first applied by him to harbour works. The diving-helmet is a most useful and convenient modification of the diving-bell, and is now very generally employed.

Diving-bell.

Beton.

Of late years Mr Walker has introduced from France the use of *beton* as a substitute for backing. This artificial concrete is sometimes used in enormous masses. We have seen at Cherbourg blocks of 50 tons prepared in boxes, whose sides and tops are removed after the concrete has set, in order to be again similarly employed. The proportions used at Cherbourg by M. Rebeille were two of sand or fine gravel, to one of Portland cement.

Edge work.

We may also mention that the method of assembling stones on their edges, instead of on their beds, which formerly was in use in some old Scottish harbours and sea-walls, as at St Andrews, Prestonpans, &c., deserves to be more generally known and adopted, from its superior strength.

Mr Bremner's pontoons.

The proposal of Mr Bremner, of Wick, for putting in the foundations of low-water piers also merits notice. Mr Bremner proposes to construct, in some adjoining place of shelter, enormous pontoons of timber, on which the under parts of the work are built, and afterwards floated to the desired spot in favourable weather, and carefully grounded. Such a plan might, we have no doubt, be found economical and useful in some situations.

Mr Rendel's method of assembling the *pierres perdues.*

Mr Rendel has introduced an improved method of assembling the *pierres perdues* or rubble used in the construction of large breakwaters; this method he employed at Millbay Pier, near Plymouth, in 1838, in a depth of 38 feet; and he is at present carrying out the same principle on a still larger scale, in the construction of the breakwaters at Holyhead and Portland. The improvement consists in depositing the rough materials from stagings of timber elevated a considerable height above high water. The stones are brought on the staging in waggons, through the bottoms of which they are discharged into the sea. The principle on which the stagings are designed is that of offering the smallest possible resistance to the sea, the under structure consisting of nothing more than single upright piles, there being only one line of piles for each roadway.

Harbours of refuge at Portland and Holyhead.

Mr Rendel, in a letter kindly communicated to us, states, "I use no timber braces of any kind, as these offer more resistance to the sea than strength to the staging. At Portland, however, where any accident would be a serious evil, owing to our employing convicts in the quarries, we stay the piles with iron guys, fixed to Mitchell's screw moorings, and also truss the outer piles in each row with iron rods. We also fix the piles in the ground with a screw.

"At Holyhead, however, we only attach to each pile boxes filled with small stones, for the purpose of getting them into a vertical position, and use no stays or guys of any kind.

"The superstructure consists simply of balks of timber, with rails laid on them to carry the waggons. The piles are placed in rows 30 feet apart, and the ease and certainty with which the staging is constructed is such that a length of 30 feet, including the screwing in of the piles, the laying down of the roadways, and all minor works necessary to make them fit to carry the waggons, never occupies more than one working day and a half, and often less. The length of the piles that we are now using varies from 84 to 90 feet, the depth of water at both Holyhead and Portland being about 11 fathoms.

"Of the strength of the stage you may judge from its carrying on each roadway as much as three waggons, weighing in the gross 12 tons each.

"The advantages of the staging are obvious. It contributes greatly to the consolidation of the stone, it makes a greater length of breakwater to be under construction at the same time, and it enables the deposits to be carried on without interruption, almost in the heaviest weather. As an instance of this, I may remark that my resident at Portland informs me that the waggons and locomotives were engaged yesterday at a time when such a sea was running that large bodies of spray were thrown 55 feet above the water level. As a proof of the facilities which the stage affords for rapidity of construction, I should state that we have deposited this year at Holyhead, where free labour is employed, nearly one million tons of stones. The loss from accidents to the stage is comparatively small on its first cost, and when spread over the cost of the whole works it is a mere trifle. I find the sea-slopes are, in the deep water and exposed parts, from $5\frac{1}{2}$ or 6 to 1 between 6 feet above high-water and from 12 to 15 below low-water, from which point they rapidly become about 1 to 1. The inside slopes are never more than $1\frac{1}{4}$ to 1, and seldom more than 1 to 1. The materials are excellent for our purpose."

Harbours of refuge at Alderney, Jersey, Dover, and Plymouth.

Mr Walker has also kindly contributed some facts connected with the construction of the great works now going on under the direction of Messrs Walker, Burgess, and Cooper at Jersey, Alderney, and Dover. At Alderney, which is a very exposed place, the *base*, up to 12 feet below low-water, is formed by stones thrown, or rather dropt in from barges. Up to low-water the work is all done by diving-helmets. The wall is faced with granite, backed with blocks of *beton* made of sand, shingle, and Portland cement. Above low-water it is faced with stone of the island, a kind of millstone-grit, and is backed with blocks of rubble set in Roman cement. The millstone-grit is raised in very large blocks. The profile is to consist of a quay, an esplanade, and a parapet.

Jersey is much the same as Alderney, but the *pell-mell* work is carried to low-water, having nearly vertical walls of conglomerate built above. Dover has nearly vertical walls, faced with granite from the very bottom, which is now 45 feet below low-water. This work was done with diving-bells.

Sir J. Rennie, in his *Account of the Plymouth Breakwater*, says, "From the bottom to within 8 feet of low-water springs, we find that the slope is $2\frac{1}{2}$ or 3 to 1. Here the effect of the waves is comparatively small, being neutralized by the mass of water. From thence to low-water of spring-tides the slope increases from 3 or 4 to 1, but between low-water of spring-tides and high-water, when the effect of the waves is greatest, there we found that the rubble would not lie at less than 5 to 1, whilst, on the inside, the slope stands generally at from $1\frac{1}{2}$ or 2 to 1."

The above interesting details regarding these national works show, from the variety which they exhibit, how difficult it is to lay down any general rules for the construction of harbours, and confirm the principle that each work must be judged of *per se*.

Miscellaneous Observations.

The reduction in the height of waves after passing into harbours, and the proper width of entrance.

The ultimate object of constructing harbours is, by lowering the height of the waves, to preserve the tranquillity of the area of water which is inclosed by the piers; and this property is variously possessed by harbours of different forms, and depends much upon the relative widths of the entrance, and of the interior, the depth of water, the shape of the entrance, and the relation between the direction of its opening, and that of the line of *maximum exposure*.

The only formula of which we are aware is that by the writer of this article (*Edin. New Phil. Journal*, 1853), which gives an approximation to the *reductive power*, or is, in other words, a numerical form of expressing how much a wave of given height becomes reduced, after it has entered a harbour. Though the results obtained by the formula may not be absolutely correct, this will be no objection where the object is merely to obtain a comparative value, as, for example, in comparing one design for a harbour with another.

When the piers are high enough to screen the inner area from the wind, where the depth is uniform, the width of entrance not very great in comparison with the width of the wave, and when the quay walls are vertical, and the distance not less than 50 feet,—let

H = height in feet of waves in the open sea.
x = reduced height of waves in feet at place of observation in the interior of the harbour.
b = breadth of entrance to harbour in feet.
B = breadth of harbour at place of observation in feet.
D = distance from mouth of harbour to place of observation in feet.

$$x = H\left\{\sqrt{\frac{b}{B}} - \frac{1}{50}\left(1 + \sqrt{\frac{b}{B}}\right)\sqrt[4]{D}\right\}$$

This formula has been found to give good approximations at several harbours where the heights of the waves were registered. When H is assumed as unity, x will represent the *reductive power* of the harbour.

Decrease in height of waves from lateral deflection.

In situations where the highest waves cross the harbour mouth at an oblique angle, a farther reduction is due to this cause. We have been unable to find any observations that have been made on this subject by others, and for want of better, we shall give three observations made under our directions at Latheronwheel harbour:—

Angle of obliquity.	Distances run through by waves.	Height of wave after passing through angle.
0°	16 feet.	1·00
50°	32 ...	0·68
140°	68 ...	0·21

These must, however, be regarded as but approximations. It is obvious that as the wave may be deflected through more than 360°, the curve representing the reduction must be a spiral; but more observations are wanted to determine of what kind.

Booms for entrance.

Booms are logs of timber placed across the mouth of a harbour or the entrance to an inner basin or dock, having their ends secured by projecting into grooves cut in the masonry on each side of the entrance. The booms are dropped into those grooves to the number of from 10 to 20, or as many more as will insure close contact of the lowest one with a sill-piece placed in the bottom of the harbour, without which precaution the swell is found to enter the harbour from below the booms. By this contrivance, which forms a temporary wall, the waves are completely checked and prevented from spreading into the interior basin. The longest booms we have seen are about 45 feet, and in some places, as at Hartlepool and Seaham in Durhamshire, they are taken out and in by steam power.

Though perfectly successful in their tranquillizing effect (provided they are kept in contact with the sill piece at the bottom), booms are not suited for the mouths of harbours where there is much traffic, as the shipping and unshipping of so many logs of timber can hardly take less than a quarter of an hour—a delay which might in many cases be attended with serious consequences.

Stilling basin for the waves.

It is very desirable, and in some cases essential, that there be either a considerable internal area, or else a separate basin opposite the entrance for the waves to destroy or *spend* themselves. Such a basin should, if possible, be made so as to preserve a portion of the original shore for the waves to break upon, and when circumstances render this impossible, there should at least be a flat talus of 2 or 3 to 1. Talus walls of 1 to 1, or steeper, will not allow the waves to break fully, but will reflect them in such a manner as might in some cases make the entrance difficult or even dangerous of access, and the berthage within unsafe. There are many instances of harbours being materially injured by the erection of a quay wall across a beach where the waves were formerly allowed to expend their force.

It may be observed that when there is an inner harbour or stilling basin, the elliptical form seems to be the most promising. Let one focus be supposed to be on the middle line of the entrance and to coincide with the point from which the waves in expanding into the interior radiate as from a centre (which they do approximately), and if the other focus is situated inland of high-water mark, the waves will tend to reassemble at the landward focus, and on their way will be destroyed by breaking on the beach. This appears from the well-known property of the ellipse, that if two *radii vectores* be drawn from the two foci to any point in the curve they will make equal angles with the tangent at that point; and as the angles of incidence and reflection of a wave from any obstacle are practically equal, each wave will be nearly concentrated at the focus opposite to that from which it emanated.

Evil of indiscriminate deepening at the entrance of harbours of small reductive power.

Another cause of disturbance in harbours, which is often not sufficiently considered, is the indiscriminate deepening of the entrance without a proportionate enlargement of the internal area, or the execution of other works for counteracting the effect. As the depth of the water is more and more increased, waves of greater height become possible at the entrance, so that larger waves gain admission to the interior. The writer has had repeated proofs of this in the course of his practice. At the port of Sunderland Mr D. Stevenson recommended the removal of nearly the whole of the south stone pier, and the substitution of works of open framework in order to tranquillize the interior. These works, which have been quite successful, were rendered necessary by the frequent dredging of the channel at and near the entrance.

Artificial scouring.

The preservation of the depth of harbours where there is a tendency to deposit is often attended with great difficulty and expense. Where the deposit of silt is confined to the space between high and low water marks, the scouring by means of salt or fresh water is in general comparatively easy, but where there is a bar outside of the entrance the case becomes most materially changed. The efficacy of the scour, so long as it is not impeded by encountering stagnant water, is kept up for great distances but soon comes to an end on its meeting the sea. Probably the only way in which this difficulty might to some extent be obviated would be by conducting the water in iron pipes to the bar, a plan which the author proposed in 1843 for Hynish harbour, but the expense was considerable and the success doubtful. The same plan was proposed by Mr Alexander Swan for Kirkcaldy some years later. When the volume of water liberated is great compared with the *alveus* or channel through which it has to pass, the objection based on the stagnancy of the water originally occupying the channel does not hold to the same extent as when the scouring is to be produced by a sudden *finite momentum*. In the one case the scouring power depends simply on the quantity liberated in a given space of time, while in the other it depends on the propelling head and the direction in which the water leaves the sluice. Mr Rendel's scheme for Birkenhead was on the former principle. The first example of artificial scouring in this country seems to be due to Smeaton who used it effectually at Ramsgate in 1779.

At Bute Docks, Cardiff, designed by Sir W. Cubitt, the access to the outer basin is kept open most successfully by means of artificial scouring on a gigantic scale. The entrance was cut through mud banks for a distance of about three-fourths of a mile seaward of high-water mark. The initial discharge when the reservoir is full, is stated to be 2500 tons per minute. The writer has known even so limited a discharge for an hour to two as one ton a minute, produce very useful effects in keeping a small tidal harbour clear of sand.

Floating breakwaters.

Many proposals have from time to time been made for mooring in the open sea floating frameworks of timber with the view of sheltering the space inclosed by them. The objections to floating breakwaters are so great and obvious that there seems little chance of their ever being much used. From what was stated on the subject of booms, it will be recollected that it is a requisite that they should fit closely to a sill piece at the bottom, otherwise the *run* is found to extend into the harbour. From what will be afterwards stated regarding the liability of timber to speedy destruction from the marine worm, and to iron by chemical action, it is obvious that floating structures of wood, connected by iron and moored by iron chains, cannot possibly be of long duration. If to all these sources of evil we add the risk of their being broken by the sea we think the case may be almost regarded as hopeless. No doubt green-heart might be employed so as to resist the ravages of the worm, but its high specific gravity and its great expense would prove bars to its employment.

Suspension piers.

In some situations where there is a long shallow beach, a harbour or pier of timber or masonry may be made at or near the low-water mark, which may be connected with the shore by means of a suspension bridge. The inducements to adopt the suspension principle are its economy, and the free passage it affords to the currents which in this way are prevented from forming accumulations of sand, silt, or gravel. These advantages are, however, much reduced by the great wear and tear consequent upon the perishable nature of the structure. The late Sir Samuel Brown erected two chain piers, the one at Brighton, and the other at Newhaven, near Edinburgh, both of which are still in existence.

Advantages of two entrances to a harbour.

In every situation where it is easily practicable to make two entrances to a harbour, it will be found well worth the extra expense, provided they can be so placed that the one shall be available when the other has become difficult of access. In harbours which have but one mouth, vessels are often detained for a great length of time by the continuance of the wind in the direction which throws a heavy sea into the entrance. Whereas if there are two entrances situated as we have supposed, vessels are at once able to take their departure by the sheltered side. At the port of Peterhead, the north and south harbours were some years ago united by a canal, according to the writer's plans, and there the advantage has been of the most marked description. Vessels can now clear out as soon as loaded, either by the north or south mouth, according to the state of the sea. Some caution is necessary, however, as the *run* is apt to extend from the one harbour to the other unless there be a considerable area.

Harbour repairs.

There is generally much prudence required in the alteration or repairs of existing marine works. The risk of having the whole structure destroyed by a gale coming suddenly on while there is an open breach in the works, must be obvious; and in one instance, where the exposure of the place was great, and the evil was a hidden one, the writer could not recommend the facework being disturbed. The cause of failure in this instance was supposed to be the decay of the backing, which having deprived the face-stones of support allowed them to be driven inwards by the force of the waves. Instead of removing the facework, the only recommendation that could be given was to inject the whole pier with fluid cement, so as, if possible, to render the mass *monolithic*. An alternative of this kind is obviously of very doubtful success, and can be regarded as nothing short of a last resort, for there is but a small chance of getting the injected fluid to permeate the whole mass of the pier. The system of permeating the masonry with fluid matter could, however, be employed with more chance of success in the *formation* of a pier, while each course lies open to view. In 1844, at a harbour that had stood for very many years, two or three faulty stones had been incautiously taken out of the facework by a mason who intended to replace them by others, when a sudden gale came on, and nearly the whole of the work was levelled with the beach.

Register of Height of Waves for 1852 *observed at Lybster, Caithness-shire.*

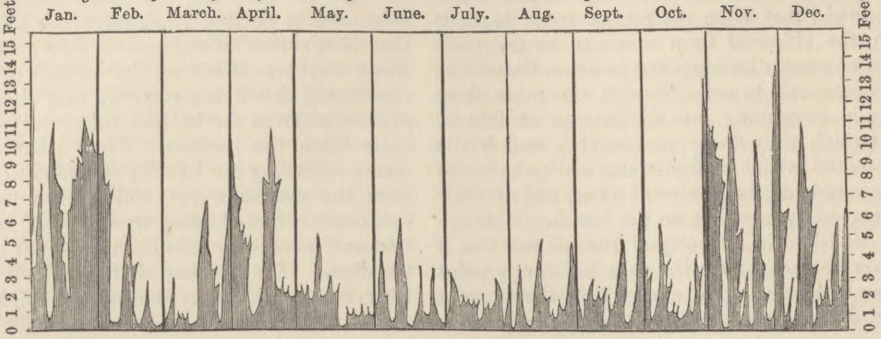

Fig. 2.

As an example of the suddenness with which our eastern coast is visited by gales, and as indicating graphically the relative eligibility of the summer and winter months for carrying on harbour works, we give the accompanying diagram of the heights of waves, as observed for the writer, by Mr William Middlemiss, resident engineer at Lybster harbour.

Timber piers.

In landlocked bays, where a deep-water landing-place is all that is required, and where the bottom is sandy or soft, timber may be employed with great advantage. Even in exposed situations, timber can also be used, but the fatal disadvantage attending its employment in most places where there is no admixture of fresh water, is the rapid destruction occasioned by marine worms.

The damage occasioned to harbours in this way is noticed by Semple in his treatise *On Building in Water* in 1776, and very probably by much earlier writers. Indeed, the ravages of the *Teredo navalis* are very ludicrously described by Hector Boece in his *Croniklis of Scotland*, printed at Edinburgh *circa* 1536. In the Atlantic Ocean the *Teredo navalis*, and at many places in the German Ocean the *Limnoria terebrans*, are the animals which are found to destroy any structure of timber which is exposed to the water. They are found to eat most rapidly between the bottom and low-water mark, but above low-water the damage is not so great; and what is singular, they do not appear to exist at all below the bottom where the pile is covered with sand. These observations do not, however, quadrate with Mr Hartley's at Liverpool, for he found the parts which were alternately wet and dry to decay faster than the parts which were constantly immersed. Even solid limestone is often destroyed by the persevering efforts of another marine animal called the *Pholas*.

The late Mr R. Stevenson made several experiments on the ravages of the *Limnoria terebrans* at the Bell Rock in 1814, 1821, 1837, and 1843, by fixing pieces of different kinds of timber to the rock, and getting regular reports on their decay. From those experiments it appeared that green-heart, beef-wood, and bullet-tree, were not attacked by the worms, while teak stood remarkably well, although suffering at last. The kyanizing fluid and other preparations have been tried, but were not found to be of permanent service. In addition to these experiments on timber, no fewer than 25 different kinds and combinations of iron were tried, including specimens of galvanized irons. Although separate specimens of each were tried in places where they were always under water, and also in places where they were alternately wet and dry, yet all the ungalvanized specimens were found to oxidize with much the same readiness. The galvanized specimens resisted oxidation for three or four years, after which the chemical action went on as quickly as in the others.

The following Table shows the different kinds of Wood which were made the subject of experiment at the Bell Rock in 1814, 1821, 1837, 1843, *with their relative durabilities.*

Kind of Timber.	Decay first observed.		Unsound and quite decayed.		Quite sound for		Remarks.
	yrs.	mo.	yrs.	mo.	yrs.	mo.	
Green-heart	...		...		13	0	
Teak-wood	...		...		13	0	Affected in one corner.

Polish Larch	1	1	1	6	...		Going fast when first observed.
Birch, Payne's patent pro.	0	10	1	10	...		

Green-heart timber is now generally had recourse to in places where the worms are destructive. It appears to have been first used by Mr J. Hartley of Liverpool, who published in the *Minutes of Institution of Civil Engineers* an account of its virtues in 1840, as ascertained at the Liverpool Docks. Its cost is considerably greater than memel or than most of the other timbers generally used. Memel logs for the inner piles of piers might perhaps, from their not being exposed to abrasion from ships, be clad with green-heart planking at those parts which are exposed to the worm. Copper sheathing and scupper nailing are often and successfully employed as protections for piles in exposed situations. *Breaming* or scorching the wood, and afterwards saturating it with train oil, also forms a partial protection.

It is much to be regretted that timber is so expensive in this country, and that some simple and economical specific against the worm has not been discovered for protecting memel and the cheaper kinds of pine. The grand desideratum in harbour works, which is the *want of continuity in the structure*, would then be supplied. It follows, from the known laws of fluids, that each individual stone in a pier which is equally exposed throughout its whole length, is subjected to a force which it can only resist by its own inertia, and the friction due to its contact with the adjoining stones. The stability of a whole hydraulic work may therefore be perilled by the use of small stones in one part of the fabric, while it is in no way increased by the introduction of heavier stones into other parts. By the use of long logs of timber carefully bolted together a new element of strength is obviously obtained. A pier could be erected almost free of sea risk if constructed of rectangular or other shaped prisms, consisting of logs of timber treenailed and bolted together, so as to form boxes, say 10 feet square and 30 or 40 feet long. The interior of the boxes would be filled with rubble or *beton*. The first layer would be arranged across the pier, so as to fit the irregularities of the bottom, and above that, they might be arranged lengthways of the pier, so as to form its outer and inner walls, the space between being filled with common rubble or *beton*.

Deposit of silt, sand, &c., and sea-bars.

In many ports the original depth has been decreased by the deposit of silt, sand, and gravel. This is, indeed, a great evil, and one which unfortunately is most difficult of cure. So obscure and apparently capricious are the causes which lead to the formation of shoals, that in the present state of our knowledge it would be little short of *quackery* to lay down any general rules for the guidance of the engineer. In fixing on the site for a harbour, all existing obstructions should be examined to ascertain whether there be a tendency to deposit, and the works should be kept as far as possible from places where the tendency is most strongly developed. The agents which occasion bars at the mouths of harbours are the waves, the tide currents, and land streams where they exist. Rivers are often more pernicious than beneficial in their effects, especially where they intersect a gravelly soil; but in some cases the descending gravel may be successfully intersected by the erection of weirs from which the accumulations must be from time to time removed. We agree with Sir H. De la Beche in believing that the bars at the mouths of rivers are most generally formed by the constant tendency of the waves to preserve the *continuity* of the beach profile. It is therefore not to be wondered at, that heavy gales should distort and fill up the narrow trench which the back waters cut in gravelly or sandy beaches. The erection of breakwaters on each side has undoubtedly a good effect in protecting the channel, but still a bar is very apt to form outside of the breakwaters. In some cases the depth of the track might probably be maintained by driving, on each side of the mid-channel, dwarf piles to which continuous walings should be attached so as to confine the current at low-water. The timber framework should not project more than a foot or two above the bottom, which in some cases might be planked. This, however, is but a hint, and has, so far as the author is aware, never been tried. The principle on which the proposal is based is that of contracting the low-water channel to a smaller width than that of the high-water channel, and thus by fixing the low-water track, to prevent a tortuous channel. The same principle was adopted by the writer with success in controlling and fixing the meanderings of a gravelly river, which is subject to very sudden and heavy freshes.

Advantages of government supplementing local funds.

The want of sufficient funds occasions a great national loss in the construction of our harbours. The history of a large majority of those ports which have been erected by private or local enterprise, presents but a record of the building of piers at one period when the funds were small, and of taking them down at another when the trade had increased and more room and accommodation were required. Want of funds often prevents the original works from being carried within deep water, and in consequence the most expensive part of the protecting breakwater is often put down just in the very place which has afterwards to be converted, at great expense, into a deep water access or berthage. Sometimes, indeed, a whole line of pier is, from motives of economy, placed in such a manner as to interfere most materially with what might have been by far the best and safest berths for shipping, so that in the further extension of the works a great part of the old harbour has to be demolished. Want of a proper marine survey has also often led to very serious errors in the position of the piers.

To such an extent has this system prevailed, that were an engineer called on to value many of our works as they exist at present, his estimate, however fairly and fully made out, would fall lamentably short of the actual cost. This estimate would proceed on a measurement of what he sees, while the actual cost would include the building of piers and jetties which had long since ceased to exist. For these reasons we conceive there could hardly be a more advisable expenditure of the public money than by a system of grants for supplementing the local funds on a liberal scale. With such aid the authorities on the spot would be enabled to protect and improve the existing physical advantages which the shores possess, by preventing the construction of proposed improvements on too narrow a scale. But a comparatively slight increase of the means would, in instances of which the writer is aware, have inclosed a great extra area, and secured a deeper access with superior internal tranquillity, the want of which now cripples the trade, and is the subject of lasting regret to all frequenting the harbours.

For other subjects connected with harbours *vide* articles on DOCKS, and PORTS.

(T. S.)

HARBURG, a seaport town of Hanover, province of Lüneburg, on the left bank of the southern branch of the Elbe, opposite Hamburg which stands on the right bank of the northern branch of that river. The distance between Harburg and Hamburg is about 4½ miles, and regular steam communication is maintained between them at least six or eight times a day. Harburg communicates also with Hanover by railway, and carries on a considerable trade, chiefly transit, between Hamburg and the countries south of the Elbe. It has manufactures of linen, hosiery, soap, starch, refined wax, leather, &c. It is a place of some strength, being surrounded by walls, and defended by a citadel. Pop. 5500.

HARDERWYK, a town of Holland, province of Guelderland, on the Zuyder Zee, 30 miles E. of Amsterdam. It is fortified on the land side, and has a barrack, a Calvinistic and a Roman Catholic church, two orphan asylums, and a gymnasium. The inhabitants are chiefly engaged in fishing and in the corn trade. Pop. 4400.

HARDICANUTE, Hardecanute, or Hardiknute, the eldest son of Canute the Great, by Emma the "Flower of Normandy," whom he had married after the death of her first husband, Ethelred II. At the time of Canute's death, Hardicanute, his eldest legitimate son, happened to be absent in Denmark, which country had been entrusted to him as his father's viceroy, and his half-brother Harold usurped the throne. Hardicanute being of an easy and self-indulgent nature, remained quietly in Denmark, giving himself no concern about his political interests. At the instance of his mother Emma, however, he had just begun to fit out a fleet for the purpose of recovering his rights, when a deputation of English barons brought him the news that the usurper was dead, and that the crown was in his gift. His reign extended over little more than two years; and was not distinguished by any event of importance. He spent his time chiefly in eating and drinking, in both of which he indulged to excess. His inglorious career was terminated by a stroke of apoplexy, June 8, 1042.

HARDNESS, that property in bodies by which they resist abrasion from the impression of any other substance. The method pursued in constructing tables of the hardness of different substances is by observing the order in which the articles tried are capable of cutting or scratching one another. The following table, extracted from Magellan's edition of Cronstedt's *Mineralogy*, was taken from Quist, Bergman, and Kirwan:—

	Hardness.	Spe. grav.		Hardness.	Spe. grav.
Diamond from Ormus	20	3·7	Sardonyx	12	2·6
Pink diamond	19	3·4	Occidental amethyst	11	2·7
Bluish diamond	19	3·3	Crystal	11	2·6
Yellowish diamond	19	3·3	Carnelian	11	2·7
Cubic diamond	18	3·2	Green jasper	11	2·7
Ruby	17	4·2	Reddish yellow ditto	9	2·6
Pale ruby, from Brazil	16	3·5	Schoerl	10	3·6
Ruby spinell	13	3·4	Tourmaline	10	3·0
Deep blue sapphire	16	3·8	Quartz	10	2·7
Ditto paler	17	3·8	Opal	10	2·6
Topaz	15	4·2	Chrysolite	10	3·7
Whitish ditto	14	3·5	Zeolite	8	2·1
Bohemian ditto	11	2·8	Fluor	7	3·5
Emerald	12	2·8	Calcareous spar	6	2·7
Garnet	12	4·4	Gypsum	5	2·3
Agate	12	2·6	Chalk	3	2·7
Onyx	12	2·6			

A similar but shorter table is now generally used, in which diamond is rated at 10.

HARDOUIN, Jean, better known as Pere Hardouin, one of the most learned, and at the same time most singular men whose names are to be found in the history of letters, was born at Quimper, in Brittany, in 1646. His youth gave little promise of his future distinction, and it was with difficulty that he was admitted into the order of the Jesuits. After the usual preliminaries he went to Paris to complete his theological studies. He there undertook to edit the *Natural History* of Pliny for the series of the Delphin Classics. In trying to determine the positions of the towns mentioned by Pliny, he became sensible that a knowledge of medals would assist him in clearing up different points of ancient geography; and with this view he immediately applied to the study of numismatics, in which he soon rendered himself profound. His edition of Pliny was completed in five years, and, when it appeared, made his name known to all Europe. This work, which, according to Huet, would have occupied any five ordinary scholars fifty years, met with so flattering a reception, that Father Hardouin could not enjoy his success with moderation. The commendations which poured in upon him from all quarters intoxicated him with pride; and he no longer spoke of other antiquaries, except with the utmost contempt. The latter in their turn depreciated his merits, and exaggerated his faults. Hardouin replied with bitterness, and at length had recourse to the wildest paradoxes in his attempt at self-defence. In one of his works, *La Chronologie expliquée par les Médailles*, he ventured to maintain that ancient history had been entirely recomposed by the monks of the thirteenth century, and that the only genuine remains of Latin antiquity were the works of Cicero and Pliny, the Georgics of Virgil, and the satires and epistles of Horace. In 1708 his ecclesiastical superiors compelled him to retract this opinion, but his retractation made no real change in his views. He died at Paris, September 3, 1729, in the eighty-third year of his age. His principal works are:

Nummi antiqui Populorum et Urbium illustrati, de re monetaria veterum Romanorum ex Plinii Secundi sententia, Paris, 1684, in 4to; *Antirrheticus de Nummis antiquis Coloniarum et Municipiorum ad Jo. Foy-Vaillant*, ibid. 1689, in 4to; *C. Plinii Secundi Historiæ Naturalis, libri xxxvii.*, Paris, 1689, in five vols. 4to; *S. Joannis Chrysostomi Epistola ad Cæsarium monachum, notis illustrata*, Paris, 1686, in 4to; *Chronologiæ ex Nummis antiquis restitutæ specimen primum*, Paris, 1696, in 4to; *Opera Selecta*, Amsterdam, 1709, 1719, in folio; *Conciliorum Collectio Regia Maxima*, Paris, 1715 and the following years; *Apologie d'Homère, où l'on explique le véritable dessein de l'Iliade, et la Théo-mythologie*, Paris, 1716, in 12mo; *Opera Varia Posthuma*, Amsterdam, 1733, in folio; *Commentarius in Novum Testamentum*, Amsterdam, 1742, in folio; *Prolegomena ad censuram Scriptorum veterum*, London, 1766, in 8vo; and a very great number of Dissertations, chiefly on Medals, in the *Mémoires de Trevoux.*

HARDWICKE, Earl of. See Yorke, *Sir Philip.*

HARE. See index to Mammalia.

HARE, Julius Charles, M.A., an eminent clergyman and dignitary of the Church of England, was born at Herstmonceux, in the county of Sussex, on the 13th of September 1795. His father, the Rev. Robert Hare, who was a younger son of Bishop Hare, held, along with the family living of Herstmonceux, the rectory of Barton Stacey, and in his later years was a prebendary of Winchester. His mother was a daughter of Dr Shipley, Bishop of St Asaph. Their family consisted of four sons, of whom the subject of this notice was the third. The oldest, Francis, and the youngest, Marcus, died early, and without having acquired distinction; the second, Augustus William, who became a fellow of New College, Oxford, and rector of Alton Barnes, Wiltshire, though prematurely cut off in 1834, has secured for himself a permanent reputation, partly as the associate of his younger and more famous brother in one of his most widely circulated publications, partly by two volumes of sermons published after his death, and of which a very impartial and competent critic has said, that "for an illiterate audience—an audience of rustics—they appear in point of diction perfect models of what discourses ought to be."[1]

The Rev. Robert Hare died while his sons were yet young. Their early education was superintended by their mother, a woman of cultivated mind, and who added to an energy derived from her father, a grace and beauty of character peculiarly her own. To her and to her sister, Lady Jones, widow of the celebrated orientalist, the subject of this notice owed much of his early training. Of his juvenile life a considerable portion was spent on the Continent, and there, it is presumed, were laid the foundations of several peculiarities both of style and sentiment by which he was afterwards characterized. After passing through the usual course at the Charter-house, he was removed to Cambridge, in 1812, where he remained, with a brief interval, for twenty years. He became a Fellow of Trinity College in 1818, and in 1822 he assumed the duties of assistant-tutor of the college. During his residence at Cambridge he was engaged in amassing that treasure of classical and philological learning which formed the basis of his intellectual furniture, and in forming that habit of mind and tendency of thought by which he was afterwards peculiarly distinguished. To this the study of German literature, and of the writings of Coleridge and Wordsworth, contributed, along with that of the literary treasures of ancient Greece and Rome. Nor were there wanting the plastic influences of congenial society and the collision of kindred minds, for Trinity College numbered then among its members, who were Mr Hare's contemporaries, not a few whose names have since added splendour to the ancient glories of that foundation. We have Mr Hare's own testimony to the effect that he owed "the building up of his mind, and much happiness for more than twenty years, to the friends he found amongst the members of Trinity College;"[1] and one of the most distinguished of these friends has recorded that when Mr Hare left Cambridge it was to his "great sorrow and that of many more."[2]

---

[1] *Edinburgh Review*, vol. lxxii., p. 86.

Whilst at Cambridge, Mr Hare published a work in two volumes, under the title of *Guesses at Truth, by Two Brothers*. Part of this work, which consists of apophthegms and reflections in various departments of knowledge, was contributed by his elder brother, but the greater part was furnished by himself. There, too, he, in conjunction with his friend the Rev. Connop Thirlwall, now Bishop of St David's, executed the translation of the first two volumes of Niebuhr's *History of Rome*, of which vol. i. was published in 1828, and vol. ii. in 1832. He also united with the same friend and some others in publishing the *Philological Museum*, a periodical of which only two volumes were completed, but which contributed much to introduce a profounder habit of studying ancient literature than had previously for several generations characterized English scholars. To this journal Mr Hare contributed largely, both by translations from the German and by original articles. Among the latter are some intended to vindicate those departures from the ordinary mode of spelling some words in which he indulged, and the uncouth appearance of which, together with some roughnesses of style, led a facetious critic to designate him punningly Julius Hirsutus.

The family living of Herstmonceux having become vacant in 1832 by the death of his uncle, Mr Hare quitted Cambridge to assume the duties of rector of that parish. Before entering upon these, however, he availed himself of the opportunity to pay a visit to the Continent, in the course of which he spent some time at Rome. Here commenced his intimacy with the Chevalier Bunsen, an intimacy which was afterwards ripened into the most cordial friendship when the latter came to reside in England as the representative of the Prussian court. When he published his great work on *Hippolytus and his Age*, the learned diplomatist dedicated part of it to Mr Hare, "as a monument of a life-long friendship;" and in the body of the work he addresses him thus,—"My dearest friend, together with whom for nearly twenty years I have had the happiness of thinking and inquiring, and in whose love of truth I have found no less comfort than in your erudition and critical judgment."[3]

At Herstmonceux, Mr Hare devoted himself with laudable fidelity to the duties of his office. He laboured to accommodate his style of thinking and speaking to his rustic auditors, with a perseverance deserving of all praise, though without, we fear, any large measure of success; at any rate, if the two published volumes of his Parish Sermons may be taken as a specimen of his ordinary teaching, the peasantry of Herstmonceux must possess a taste for "painful preaching" exceeding even that of the Puritans, if they did not many a time weary for the close of his discourse. Nor did he much excel in the more private duties of a parish minister. The truth is, he was not quite in his place in such a sphere. His habits and the peculiar cast of his mind fitted him rather for the study than the pulpit, and for intercourse with the learned and the thoughtful than for acting the part of a teacher or a comforter of the illiterate. He had collected a magnificent library, to which he went on continually adding, until it had covered nearly all the inside walls of his rectory; and it was his delight to pursue, amidst these treasures of literature, with painstaking minuteness, researches into those departments to which he had addicted himself, and which, besides philology, embraced history, philosophy, and theology. The stores thus accumulated he delighted also to communicate to all who were privileged to enjoy his friendship, though it must be confessed that the stream sometimes came forth with a volume and a rapidity that made it impossible for less capacious minds to sustain themselves under it. As a preacher he was more in his place at Cambridge, where he delivered the two courses of sermons afterwards published under the title of *The Victory of Faith*, 8vo, 1840, and *The Mission of the Comforter*, 2 vols. 8vo, 1846; but even with such an audience there was something in his style of thought and expression that stood in the way of his success; and it is even recorded that on one occasion the spirit of undergraduate impatience found utterance, and his sermon "was closed amidst the audible scrapings and shufflings of a multitude of invisible feet on all sides of the eloquent preacher."[4] When in 1840 he was appointed Archdeacon of Lewes, a still more congenial and suitable sphere was secured to him for the exercise of his peculiar powers, in the periodical charges which it formed part of his official duty to deliver to the clergy of that archdeaconry; though it must be confessed that even here also the acceptibility and usefulness of his addresses were not a little marred by that excessive prolixity which was the besetting sin of his written discourses. "If I had been one of his clergy," said an eminent prelate, after looking over one of his published charges, "and been *charged* in that style, I should have been like a gun—I should have *gone off*."

Sometime after settling at Herstmonceux, Mr Hare married a sister of his friend and former pupil, the Rev. F. D. Maurice. This union was a source of unfailing happiness to him, as well as in some respects of spiritual enlightenment and comfort. An internal disorder, to which he was subject, and under which his strength gradually sank, rendered invaluable the society and the tender care of such a partner. To her it was given to "cast a steady sunshine over his life" during its latest years. These years were years of unremitting toil, though also of frequent suffering and progressive decay. He delivered his last charge to his clergy in the autumn of 1854; he spoke with difficulty, and all could see that the hand of death was upon him; but he lingered on till the 23d of January 1855, when he peacefully expired in the arms of his wife. He was buried at Herstmonceux on the 30th of the same month.

[1] Dedication of *The Victory of Faith*.

[2] Whewell's Dedication of *Four Sermons on the Foundation of Morals*.

[3] Vol. i., p. 330, 2d edit.

[4] *Quarterly Review*, No. 193, p. 14.

The works of Archdeacon Hare are chiefly theological and controversial. His translation of Niebuhr, and his contributions to the *Philological Museum*, constitute the whole of what he did of a purely literary character, if we except some early and unacknowledged translations from the German, and a few portions of the *Guesses at Truth.* His theological writings consist almost exclusively of sermons preached either in the ordinary course of parish duty or on special occasions. The most important in every point of view is his *Mission of the Comforter*, a series of discourses on John xvi. 7–11, followed by an immense mass of notes. His published charges are numerous, and relate to almost all the more prominent topics of public interest affecting religion which have been before the mind of the public during the last fourteen years of his life. Besides these, most of which are of a controversial character, he was the author of several publications on controverted topics; and at the time of his death he was engaged on the revisal of the largest and perhaps the weightiest of these, his *Vindication of Luther*, which had first appeared as a note to the *Mission of the Comforter.* So many of these controversial publications were devoted to the vindication of others, that he used to say playfully that he should one day collect them all in one volume, under the title of "Vindiciæ Harianæ, or the Hare with many friends,"[1] a witticism which, though not original, was one to which he had a hereditary right, the title of the old fable having been jocularly applied by the famous Duchess of Gordon to his relative, James Hare. His *Life of Sterling* may be regarded as coming under the head of these friendly vindications.

As a writer, Archdeacon Hare is distinguished by breadth of view, copiousness and accuracy of learning, massiveness of conception, and an earnest but not very dexterous handling of his materials. His writings have been defrauded of their proper influence and reputation, partly by his orthographical peculiarities, principally by his rugged and operose style. Though thoroughly, almost fastidiously, English in respect of words and idioms, his style was German rather than English in respect of the construction of sentences. This was especially unfavourable to him as a controversialist. The great defect of his writings in this department is their want of point. An intelligent reader cannot but see that the true answer which the side espoused by the writer demands is there, but it is so involved in the mass of matter that it fails to tell as it otherwise might. In spite of such drawbacks, however, these writings contain such a vast amount of sound and wise thinking, are so pervaded by an almost boundless learning, and indicate such a truth-loving, just, and earnest spirit, that they cannot fail to secure for their author a permanent place among the theological writers of his age and country.

As a churchman, Archdeacon Hare belonged to what has been called the Broad Church, not so much from any latitudinarianism on the part of those composing it, as from the eclectic tendency of their theological studies. With the spirit of this party he was deeply imbued. He sought truth wherever it was to be found, and he embraced it when found with a simple and loving spirit. Standing aloof alike from Puseyite and Evangelical, he sought to admire what might be good in either party, or to learn from either whatever it had to teach that was true. On the cardinal truths of Christianity his opinions, as expounded in his writings, are very much those of the Evangelical Arminian school; though on some points, such as the nature of the atonement, his views seem vague and indefinite. See *Quarterly Review*, No. 193, and *British and Foreign and Evangelical Review*, No. V. (W. L. A.)

HAREM. See CONSTANTINOPLE, TURKEY.

HARFLEUR (*Harfloricum*), a small town of France, department of Seine-Inférieure, on the Lézarde, about a mile from its confluence with the Seine, and 4 miles E.N.E. of Havre, on the railway between that town and Paris. It has a fine Gothic church, surmounted by a beautiful tower and spire; and has some manufactures of earthenware, and a sugar refinery. In the middle ages it was an important fortress and harbour. It was taken in 1415 by the English, who expelled the inhabitants and re-peopled the town. In 1433 it was recovered by the French; in 1440 it was again stormed by the English, but was about ten years afterwards finally captured from them by Charles VII. of France. The fortifications have been demolished, and the harbour is now dried up. Pop. about 1700.

HARIHARA, a town and fortress of Southern Hindustan, at the N.E. quarter of the native kingdom of Mysore, on the S.E. bank of the Toombuddra River. In the fort there is a celebrated temple of Vishnu, and among the inhabitants there are many of low caste. The British cantonment here is situate on an extensive plain, 1500 yards from the river, towards which the ground gently slopes. The water of the river is good, but the distance renders it inconvenient to resort to it for a supply, so that it is generally obtained from wells, being usually found at a depth of about 40 feet. The elevation of the cantonment above the sea is about 1900 feet. The place being formerly situated on the confines of two countries, has often changed masters. After the defeat of Ram Rajah, and the destruction of the Bijanagur sovereignty, it became subject to the Adil Shahee dynasty of Bejapore. On the destruction of the dynasty by the Moguls, it fell into the hands of the nabob of Savanoor, from whom it was afterwards taken by the rajah of Ikery, who was expelled by the Mahrattas; and these, after a period of fifteen years, were driven out by Hyder. On the death of Tippoo, and the division of his country, it was one of the districts ceded to the British, and is now included in the state of Mysore. E. Long. 75. 51., N. Lat. 14. 31.

HARINGTON, SIR JOHN, an English poet, was born at Kelston, near Bath, in 1561, instructed in classical learning at Eton School, and thence removed to Cambridge, where he took his degree in arts. At the age of thirty, he published a translation of the *Orlando Furioso*, which, though executed without spirit or even accuracy, enriched our poetry with new stores of imagery and romance. Harington was knighted in the field by Essex, to the great displeasure of the queen, who wished all such honours to emanate from herself; and in the reign of King James he was created a knight of the Bath. He was a favourite of Prince Henry, to whom he presented a manuscript, directed chiefly against married bishops. This production was intended for the private use of the prince; but being afterwards published, it raised a great clamour against the author, who had otherwise incurred suspicion, if not odium, by supporting Raleigh in his suit for the manor of Banwell, belonging to the bishopric of Bath and Wells, on the presumption that the actual incumbent had incurred a *præmunire* by marrying a second wife. Sir John died in 1612. His epigrams, which were the most popular of his works, though possessing little poetical merit, appeared first in 1618, and afterwards in 1625. The *Nugæ Antiquæ*, a miscellaneous collection of his works, was published in 1792, and again in 1804, with illustrative notes and a memoir of the author.

HARLEQUIN, in the Italian comedy, a buffoon dressed in parti-coloured clothes, and answering to our merry-andrew or jack-pudding. Harlequin has also been introduced upon our stage, and is one of the standing characters in the modern pantomime. The term, according to Ménage, took its origin from a famous Italian comedian who appeared at Paris in the time of Henry III., and, from frequenting the house of M. de Harlay, was called by his companions *Harlequino*, little Harlay.

---

[1] *Quarterly Review*, No. 193, p. 24.

HARLEY, Robert, Earl of Oxford, was born in 1661. His father, Sir Edward Harley, was the head of a great Puritan family in Herefordshire, who had distinguished himself in the long parliament, and commanded a regiment under Essex, but who, when Cromwell and his party had crushed every thing that stood in their way, had gone into opposition, and when at length the Restoration was mooted, did his best to promote it. For his services he was made governor of Dunkerque. His son, Robert, entering parliament at the Revolution as member for Tregony in Cornwall, and afterwards for Radnor, distinguished himself at first as an intolerant and vindictive Whig. It was soon noticed, however, that his favourite companions were men whose political creed was exactly the opposite of his own. He called himself a Whig of the old stamp, and professed to hold kings generally in abhorrence. The cavaliers hated the reigning king, whom they called a usurper: and thus it was that Harley combined with them in thwarting William whenever occasion offered. He was thus cautiously paving the way for a change which he had long meditated. After the general election of 1690, he began gradually, though almost imperceptibly, to identify himself with the Tory party, with whom he now voted almost regularly. Though a man of mean capacity, and a poor speaker, he yet possessed many qualities which made him a valuable partizan,—indefatigable industry, a large extent of reading, especially of the antiquarian kind—and as, unlike most of the political celebrities of that day, he had no very scandalous vices, his moral weight was a great deal higher than it deserved to be. As was natural he soon rose; he was made speaker under the Tory administration of Godolphin in 1701; in the next parliament he was re-appointed, and held the office till he was made Secretary of State in April 1704. His elevation he is known to have owed in good part to the intrigues of Mrs Masham, whose marriage Harley had brought about, and who requited the favour by exerting on his behalf her interest with the Queen. That influence was now daily on the ascendant; and the once colossal power of the Marlboroughs was waning fast. An accident, however, once more changed the aspect of affairs. A clerk of Harley's was detected in a treasonable correspondence with the French Court, and was condemned to death. The popular outcry was strong against Harley, who may perhaps at this time have been innocent; and Marlborough and Godolphin, taking advantage of it, compelled the Queen to dismiss her favourite. His disgrace, however, was of short continuance, for, aided again by the favour of Mrs Masham, Harley was in 1710 made Chancellor of the Exchequer, in room of Godolphin, who resigned in that year with all his followers, and left the field open to an administration completely Tory. The influence of Mrs Masham was now supreme with Anne, and the whole Marlborough clique was discarded from court, as well as from office. Very opportunely for Harley's interests, an unsuccessful attempt made upon his life by a French agent, calling himself the Marquis de Guiscard, quieted the doubts of the Tories, who had again begun to doubt his loyalty. Two months after the outrage on his person, Harley was made Lord High Treasurer, and was rewarded with the earldom of Oxford and Mortimer, and invested with the Garter. But by far the most memorable act of his administration was the peace of Utrecht, concluded May 5, 1713. This had hardly been effected when Harley and Bolingbroke, who had hitherto acted in concert, and to whom the credit of the peace, such as it was, was chiefly due, turned into open rivalry the secret jealousy which had been fermenting between them for some time before, and began to plot each other's ruin. Harley, thinking himself independent of Mrs Masham, ceased to pay court to her as before. His rival took advantage of the mistake, and procured his dismissal July 27, 1714; but did not long enjoy his triumph, for the Queen's death a few days after terminated the public career of both. It was not known then, though the researches of Sir James Mackintosh have now put it beyond a doubt, that both Harley and Bolingbroke had been latterly in treasonable correspondence with the court of Versailles. It is not unlikely that that charge might have been made good had the trial been proceeded with when both were impeached in the August of 1715. But Bolingbroke escaped to France; and Harley, after pining for about two years in the Tower, was acquitted and set at liberty. After this he retired into private life to enjoy the society of his literary friends, and his books and MSS., to which he was deeply attached. He died May 21, 1724. The brilliant analysis of Harley's character given by Macaulay (*Hist. Eng.*, vol. iv., pp. 463-4-5), does not seem to account sufficiently for the power which Harley attained, and the influence he exercised among the men who surrounded him, who were nearly all alike unprincipled.

Harley, as has been already said, loved books and the society of men of genius and learning. He even aspired himself to shine as a wit and poet; but his works, both in prose and verse, have small chance of immortality. He was the author of a letter to Swift *On Correcting and Improving the English Tongue;* an *Essay on Public Credit*, which he seems to have little understood in practice;—for he organized government lotteries, granted monopolies, &c.;—and a *Vindication of the Rights of the Commons of England.* For an account of his splendid collection of books and MSS. see Museum, *British.*

HARLINGEN, or HAARLINGEN, a fortified seaport town of Holland, province of West Friesland, on the entrance to the Zuyder-Zee, 16 miles W. of Leeuwarden, with which it is connected by a canal. It is intersected by numerous canals, bordered with trees, and the streets are generally regular and clean. It has a neat town-hall, six churches, a synagogue, an orphan asylum, and numerous schools. There is a good harbour, but on account of sandbanks at its entrance it is not accessible to large vessels. Harlingen has manufactures of sail-cloth, gin, bricks, paper, salt, and an extensive foreign trade. Among its exports are cattle, butter, cheese, fruit, vegetables, flax, hemp, and wool. Pop. (1850) 8591.

HARMATTAN, the name of a dry hot wind which blows periodically from the interior of Africa towards the Atlantic Ocean. It prevails in December, January, and February, and is usually accompanied by a haze which often obscures the sun for several days together. It has a withering effect on vegetation, and even affects the human body so as to cause the skin to peel off. See Physical Geography.

HARMODIUS, whose name is always associated with that of his friend Aristogeiton, was regarded by the Athenians, after the expulsion of the Pisistratids, as one of their noblest patriots. The circumstances, however, which led them to the murder of Hipparchus were entirely of a personal, and not of a political nature; and when divested of all the romance attached to them by the song and ballad writers of Greece, prove that the friends are entitled to rank no higher than common assassins. The real relations subsisting between them are fully described by Thucydides, Book vi., chap. 54.

HARMONIA, in *Grecian Mythology*, the wife of Cadmus, was the daughter of Mars and Venus, or, as others say, of Jupiter and Electra. On the day of her marriage all the gods came from Olympus to witness the ceremony. The necklace and the *peplus*, or robe, which her husband presented to her on that occasion obtained a sad renown in the old mythology, from the evils they brought upon all who wore them. Polynices, into whose hands it passed, used it to bribe Eriphyle to disclose the retreat of her husband, Amphiaraus, who had hidden himself that he might escape from the Theban expedition, in which it had been foretold that he would perish. He did perish, and his son Alcmæon, hearing how his fate had been accomplished, slew his mother Eriphyle. The fatal necklace next passed to Arsinoë, then to Pronous, and Agenor, and was finally dedicated in the temple of Minerva at Delphi by Amphoterus and Acarnan, the sons of Alcmæon. Even then, however, it did not lose its powers of working mischief. The tyrant Phyllus stole it from the temple, and gave it to his mistress, who wore it for a time. Her son, however, was struck with madness, and in a frenzy set fire to the house in which his mother was. She was burnt to death, and all her treasures were consumed in the same fire which destroyed herself.

HARMONICA, a musical instrument, consisting of a number of glass cups fixed upon a revolving spindle, and made to vibrate by friction applied to their edges. Mr Puckeridge, an Irishman, is said to have been the first to use a set of drinking-glasses, fixed on a table, and tuned to form a scale by putting more or less water into each. They were made to sound by passing a wet finger round their edges. These were improved by Mr Delaval, and still further by Dr Franklin, and were called "the musical glasses." Their tone is sweet and melancholy, and of a peculiar *timbre*, which produces a painful effect on the nerves of some persons. It appears, however, that the use of musical drinking-glasses was described in a work (*Mathematische und Philosophische Erquickstunden*) published by G. P. Harsdorfer, at Nuremberg in 1677. What was called a harpsichord-harmonica, in which finger-keys like those of a pianoforte were used instead of direct contact of the fingers with the revolving glasses, was invented by Röllig at Vienna, and Klein at Presburg. Another harmonica was invented by the Abate Mazzucchi, who employed the friction of a hair-bow to produce the sounds of the glasses. A stringed harmonica was invented at Augusta, in 1788, by John Stein, an eminent organ-builder. It consisted of a double stringed (wired) pianoforte, combined with a sort of spinet, to be used together or separately. Its effects are said to have been remarkable. (G. F. G.)

HARMONICS. See Acoustics, vol. ii., p. 107.

Harmonics (acute), their production and ratios. See Music, §§ 1 and 2.

HARMONIUM, a musical instrument recently constructed by Alexandre of Paris. It has a key-board, like a pianoforte, and the sounds (which resemble those of organ-pipes) are produced by thin plates of metal, fixed at one end and free at the other, and which are caused to vibrate by means of a current of air from bellows. It is so constructed as to play either *legato* or *staccato* passages, and can swell or diminish the sounds at pleasure. Many years ago an instrument of the very same kind, called an *Eolodicon*, was invented by Eschenbach, and constructed by Voigt, a musical-instrument maker at Schweinfurt in Franconia. It was a handsome-looking instrument, and easily transportable, weighing only about 150 pounds. Its tones were beautiful, and it had the great advantage of never getting out of tune. The Eolophone is an instrument of a similar kind. (G. F. G.)

HARMONY, in *Music*. See Music, § *Harmony*.

HARMOSTÆ, in English Harmosts, were the magistrates sent by the Lacedæmonians after the Peloponnesian War to administer the government among the towns which at that time fell into their power. The limits of their power and the length of their tenure of office do not seem to have been very strictly defined. Though their commission, therefore, was to prepare the conquered cities for the re-enjoyment of their ancient liberties, they were never called to give any account of their government, which was generally more harsh and oppressive than that of the Spartans themselves.

HARO, anciently *Castrum Bilium*, a secular town of Spain, in the province of Burgos, and bishopric of Calahorra. It contains two parish churches, one Augustinian convent, one hospital, and one house of refuge; and is the centre of one of the most beautiful and fertile spots in Spain. Pop. 6235.

HAROLD I., surnamed Harefoot, was the second son of Canute the Great, by Alfgiva. On his father's death he usurped the English throne, which had been bequeathed to Hardicanute, and held it till his death in 1040. Nothing whatever is known with certainty about his character. The very reasons of his surname are disputed, some maintaining that he owed it to his swiftness of foot; others to the fact that his foot was covered with hair.

Harold II., the last Saxon king of England, was the second son of Godwin, Earl of Kent, and succeeded to the throne on the death of Edward the Confessor, January 5, 1066. His history is that of his country, and is given in minute detail in art. England. His life has afforded the materials for one of the best of Sir E. L. Bulwer's historical novels,—that of *Harold*.

HARP, a stringed instrument of music, traceable to a very remote antiquity, as is shown by the harps painted on the walls of tombs at Thebes, and described in Bruce's *Travels*, and in the splendid French work *Description de l'Egypte*. Jones and Parry have written upon the Welsh harp, Bunting upon the Irish harp, and Gunn upon the harp of the Scottish Highlanders. The modern double-action harp of Sebastian Erard has a compass of six octaves, from E to E, with all the semitones, and even quarter tones. For some observations on the harp, and especially the Irish harp and its scale, see G. F. Graham's Dissertation prefixed to Wood's *Songs of Ireland*, 1854.

HARPAGINES (ἁρπάγη), in *Antiquity*, grappling-irons which were flung with violence against the rigging of an enemy's ship, and, when entangled there, were used to drag the ship within reach, so that it might be boarded to more advantage, or destroyed.

HARPE, Jean François de la, a distinguished French littérateur of the eighteenth century, was born at Paris in 1739. Some Sisters of Charity found him abandoned by his parents in the Rue de la Harpe, whence he took his name. They took care of his early years, till he was admitted as a bursar into the Collége d'Harcourt, where he distinguished himself by his zeal and success in his studies. On leaving it he wrote a pasquinade against the masters, and was especially severe on his own old tutor, from whom he had experienced nothing but kindness. This ingratitude landed him in the house of correction at For l'Evêque, where he was detained for some months. Society was now closed against him, both by the accident of his birth and his own misconduct, and he betook himself to literature as the only career open to him. In 1763 he produced his tragedy of *Warwick*, which had great success on the stage. Grimm characterized it very truly when he said of it, "On dirait que c'est le coup d'essais d'un jeune homme de soixante ans. J' aimerais bien mieux y remarquer plus d'inégalité et de force et moins de sagesse." His other works in the same vein, *Timoléon*, *Pharamond*, and *Gustave Wasa*, were total failures. On the strength of his *Warwick*, La Harpe had married in 1764, and he now went to Ferney and lived there with Voltaire, who described him as "un four qui chauffe toujours, et ne cuit jamais." A quarrel with the patriarch of French literature, however, once more drove him to Paris, where he earned a precarious livelihood by writing éloges and essays on subjects open to competition, as well as a large number of dramas and translations from the Greek and English. In 1770 La Harpe became editor of the *Mercure de France*, and involved himself in quarrels with many fellow-littérateurs from the bitterness and personality of his criticisms. These qualities were especially manifest in his correspondence with the Grand Duke Paul of Russia, in which he dwells with acrid bitterness on all his rivals, while he expatiates with an amusing self-complacency on his own merits. But the work which above all the rest has preserved La Harpe's name, is his *Lycée, ou Cours de Littérature.* Till within a few years past, the dearth in French literature of what are called *ouvrages de haute critique*, maintained La Harpe's work in its high place; but it is now being gradually superseded. Even still, however, it is a useful guide to students of French literature, of which it traces the history from the earliest times to the beginning of the nineteenth century. The first part of the work is of little value, and the portion devoted to contemporary writers is worse that valueless. Malebranche professed to see all things in God; in the men of his time La Harpe could see nothing except through the distorting prism of his vain and intolerant jealousy. Grimm said of him in 1779,—"La Harpe has much more wit than knowledge, much less wit than talent, and much less imagination than taste." It is unfortunate that circumstances have always forced him to waste his time in speaking evil of his neighbours, and in defending himself from the enemies whom he thus raised up against himself every day. When the Revolution broke out, it had no more ardent supporter than La Harpe. But when on his refusal to countenance the extremes to which the republicans were going he was cast into prison, his views experienced a complete change, and he became a staunch supporter of church and crown. His new politics he soon found more dangerous than his old, and he was at length forced to fly for his life. After the 18th Brumaire, he resumed his lectures at the Lycée, which he continued till within a short time of his death. His boldness of speech displeased the First Consul, who appointed him his future residence at Orleans. La Harpe, however, soon after returned to Paris, where he died February 11, 1803.

HARPER'S FERRY, a village in the state of Virginia, North America, at the confluence of the Shenandoah with the Potomac, where the united stream breaks through the Blue Ridge, 53 miles N.W. of Washington. The scenery is highly picturesque, and the river is here spanned by a fine bridge about 800 feet in length. There is here a national arsenal containing from 80,000 to 90,000 stand of arms, and an armoury employing 250 person, and producing annually about 10,000 stand of arms. Pop. (1850) 1747.

HARPINGS, the fore-part of the wales which encompass the bow of a ship, and are fastened to the stem, being thicker than the after-part of the wales, in order to strengthen the ship in this place, where she sustains the greatest shock of resistance in plunging into the sea, or dividing it, under a great pressure of sail.

HARPOCRATES, in *Ancient Mythology*, the son of Osiris, who has been identified with Horus, the Egyptian god of the sun. He was the god of mystery and silence, and, on that account, used to be represented as having been born with his finger on his mouth. His worship was widely spread throughout Greece, and even in Rome itself, where at one time his worship was interdicted by the senate on account of the excesses which marked the mysterious festivals. He filled in the Egyptian mythology the place which Apollo occupied in that of Greece. His statue stood at the entrance of most of the Egyptian temples. The figure was that of a naked youth crowned with an Egyptian mitre, holding in one hand a cornucopia, and sometimes a lotus flower, sometimes a quiver.

HARPOCRATION, Valerius, a grammarian of Alexandria, in Egypt, respecting whose personal history nothing is known. Even the period during which he flourished is doubtful. Some have considered him to be the Greek instructor of the Emperor L. Verus, mentioned by Julius Capitolinus (*Life of Verus*, c. 2), while others have made him live so late as A.D. 360, because several passages are found in his work taken from Athenæus, who is supposed to have flourished about A.D. 300. Harpocration is the author of a very valuable lexicon on the ten orators, which contains a great deal of information on the law, history, antiquities, and general literature of Athens. The value of this work is much enhanced by the fact that all the authorities from which it has been compiled are lost. Suidas and the author of the *Etymologicum Magnum* have both borrowed from this work. Harpocration is also the author of a work entitled 'Ανθηρων Συναγωγη, a "Collection of Flowery Extracts" from various authors. The first edition of the lexicon was published along with Ulpian's *Scholia to the Philippics of Demosthenes*, by Aldus, Ven. 1503. Of subsequent editions, the best is that of Dindorf, Leipsic, 1824, 2 vols.; on which no improvements of much value will be found in the more recent one published by Bekker at Berlin in 1833.

HARPONULLY, a district in the S. of India, bounded on the N. by the Toombuddra River, and situated between the 14th and 16th degrees of N. Lat. It is a fertile country, and not so hilly as some of the adjacent districts; and it possesses the strong fortress of Ouchimadroog. The rajah of this district was tributary to the kings of Bejanagur and Bejapore, to the Moguls, and the Mahrattas; in 1774 he became tributary to Hyder, and in 1786 he was completely subdued by Tippoo, and sent prisoner to Seringapatam. On the capture of that city, Harponully was assigned to the nizam as a portion of his division of Tippoo's territory, and by him assigned to the British in 1800. It is now included in the Bellary collectorship, and is yearly improving in value. Harponully is 170 miles N.N.W. from Seringapatam. E. Long. 76. 2., N. Lat. 14. 47.

HARPOON, or Harping-Iron, a spear or javelin used for striking whales, &c. The *gun-harpoon* is a weapon used for the same purpose, but it is fired from a gun instead of being thrown by the hand. It is formed entirely of metal, and has a chain attached to it, to which the line is fastened. See Scoresby's *Arctic Regions.*

HARPSICHORD, a musical instrument in which the sounds are produced by stretched wires. The spinet and virginals, &c., preceded the harpsichord, which was an improvement on them; and all of these were derived from the harp. Each was really a horizontal harp inclosed in a sonorous case; the wires being struck by jacks moved by finger-keys. In the beginning of the eighteenth century the pianoforte was invented as an improvement upon the harpsichord. Instead of the jacks armed with crowquills which struck the harpsichord wires, hammers covered with prepared leather were used in the pianoforte. Mason, the English poet and amateur musician, introduced great improvements in the mechanism of the keys and hammers. Clementi, Broadwood, and other makers in London, have, since then, so greatly improved the pianoforte as to justify its being considered, in its latest form, almost an English instrument. See Pianoforte.

HARPYIÆ, or Harpies, in *Grecian Mythology*, fabulous monsters sometimes employed by the gods as the ministers of their vengeance. About their numbers and their parentage very various accounts are given. They are usually represented as two, or at most three in number; and as being the daughters of Neptune and Terra, or of Typhon. They are described as living in the islands called the Strophades, at the entrance of Orcus. They were originally represented as maidens, with wings and long flowing hair, and great swiftness of flight. They gradually became changed, however, into hideous monsters, of fierce and loathsome aspect, and living in an atmosphere that exhaled an intolerable stench. The most celebrated myth with which they are identified is that of the blind Phineus, who no sooner sat down to a meal than these foul creatures came swooping down and carried it off in their claws. In the midst of his distress the Argonauts came to his house, and he promised to aid them in their quest if they would rid him of his tormentors. The Boreades Calais and Zetes attacked them, and would have slain them had they not promised to molest Phineus no more.

HARQUEBUSS, an old species of gun, of the length of a musket, and cocked by means of a wheel. It carried a ball that weighed 1⅞th oz. A larger sort, called the great harquebuss, used in fortresses, carried a ball of about 3½ ounces. It is sometimes styled *arquebuse*, and *haquebut*.

HARRIER, a kind of hound, endowed with an acute sense of smell, and used in hunting hares. See Hound.

HARRINGTON, a small seaport town of Cumberlandshire, 5 miles N. of Whitehaven, of which it is a sub-port. It is of modern date and neatly built. The harbour has 8 feet water; and at the pier-head is a fixed light 44 feet high, seen 11 miles off. Its chief exports are coal and lime. It has a station on the Whitehaven Junction Railway. Pop. of parish (1851) 2169.

HARRINGTON, James, the author of the *Occana*, was sprung from an ancient family in Rutlandshire, and was born in 1611. In his eighteenth year he entered Trinity College, Oxford, as a gentleman commoner. His tutor was the famous Chillingworth. At the close of his university career (during which he lost his father) he set out to travel on the Continent. He visited France and Italy, but most of his time was spent at the Hague, where he enjoyed the friendship of the Prince of Orange, who, when Harrington returned to England, entrusted to him the care of his interests there. On reaching home Harrington retired into the seclusion of private life, chiefly for the purpose of working out his thoughts on the philosophy of politics; but in 1646 he was appointed groom of the bed-chamber to Charles I., then the prisoner of his own subjects. The king enjoyed greatly his society and conversation; but on his removal to the Isle of Wight was deprived of his pleasant companion, who was put into confinement for refusing to swear that he would not help the king to escape if he made the attempt. His devotion to his royal master was such, that on the day of his execution he went with him to the block. After Charles's death Harrington once more withdrew into private life, and devoted his time to his *Oceana*. He made no secret of the purport of this work, which was avowedly republican in its tendency; and the author soon became an object of marked suspicion both with the Royalists and the leading men of the Commonwealth. When the *Oceana* was passing through the press it was seized by order of Cromwell, but restored to its author at the instance of the Protector's favourite daughter Mrs Claypole, whose sympathies Harrington had enlisted by an ingenious ruse, of which a full account is given in his *Life* by Toland. The leading principles of the *Oceana* are, that the natural element of power in states is property, and that of all kinds of property that in land is the most important, as it possesses certain characteristics which distinguish it in its natural and political action from all other property. Carrying out this principle, he insists on what he calls an equal Agrarian law as the basis of his imaginary republic. Another feature of the *Oceana* not to be overlooked is the plan of the vote by ballot, which Harrington advocates with great power. Many answers to the *Oceana* soon appeared. The most memorable of these was Baxter's *Holy Commonwealth*, which, however, was publicly burned at Oxford in 1683, along with the political writings of Hobbes and Milton. Harrington defended himself against these attacks both by his pen and by propagating his doctrines through the medium of the "Rota," a club which he instituted, and where he nightly lectured and discoursed on the advantages of his republic. At the Restoration this club was dissolved, but its founder was seized and thrown into prison as a conspirator. He vehemently denied the truth of the charges brought against him, but it was in vain that he applied either for his freedom or a public trial. His mind at last gave way, and his liberty was then restored. By skilful treatment his health was re-established, but his faculties never recovered their tone. He now married, but survived his marriage for only a short time, dying September 11, 1677, at the age of sixty-six.

Hallam, in his *Literature of Europe* (iv. 367), remarks of Harrington, "In general it may be said of him that he is prolix, dull, pedantic, yet seldom profound; but sometimes redeems himself by just observations." This is true of the style of the *Oceana*; but it is extremely unjust to the ingenuity, truth, and depth of many of Harrington's views on political philosophy. It is not fair to deny him the praise, undoubtedly due, of having expounded and illustrated the views he adopts more clearly than any preceding writer. Harrington's complete works were published in 1700 by Toland; and a more complete edition in 1737 by Birch.

HARRIOT, Thomas, an eminent mathematician, was born at Oxford in 1560. After the usual preparatory training, he entered St Mary Hall as a commoner, and took his bachelor's degree in 1579. He then distinguished himself by his skill in the mathematics, and became preceptor in that science to Sir Walter Raleigh. In 1585 he accompanied the first colony sent out to Virginia; and having surveyed that country, ascertained its natural productions, and observed the manners and customs of the aboriginal population, he published an account of it, which was afterwards reprinted in Hakluyt's *Voyages*. On his return to England, after an absence of two years, he resumed his mathematical studies with such zeal and success, that Henry, Earl of Northumberland, the liberal and enlightened protector of the learned, assigned him a yearly pension of L.120. The same nobleman also pensioned Robert Hues, known by his Treatise on the Globes, and Walter Warner, who is supposed to have communicated to Harvey the first hint concerning the circulation of the blood. Both these persons were mathematicians; and, in 1608, when the earl was committed to the Tower for life, they, along with Harriot, were his constant companions, and usually styled his magicians. They had a table at the charge of the earl, who constantly conversed with them, to beguile the tedium of his confinement as did also Sir Walter Raleigh, who was then a prisoner in the Tower. Harriot lived for some time at Sion College, and died at London on the 2d of July 1621, at the age of sixty, after having suffered much from a cancer in the lip, occasioned by a habit he had contracted of holding in his mouth instruments of brass often charged with verdigris. He was universally esteemed on account of his learning. A manuscript of his entitled *Ephemeris Chrysometria* is preserved in Sion College; and his *Artis Analyticæ Praxis ad Æquationes Algebraicas resolvendas* was published at London in 1631, folio. Descartes has been charged with taking from this book many improvements in algebra, which he afterwards published to the world as his own; but notwithstanding all that has been said by Wallis in his account of the discoveries of Harriot, and by Zach in the *Astronomical Ephemeris* for 1788, there seems to be no good ground for the charge; and it would even appear that much that incontestibly belongs to Vieta or Descartes has been ascribed to Harriot. Montucla has reduced to their just value the services of the English mathematician, and shown that these, when truly estimated, are sufficiently important to entitle him to a place in the second rank, amongst those men who have contributed to the progress of the mathematical sciences. (See Dissertations Third and Fourth, prefixed to this work.) From some papers of Harriot, discovered in 1784, it appears that he had either procured a telescope from Holland, or divined the construction of that instrument; and that he coincided, in point of time, with Galileo in discovering the spots on the sun's disc.

HARRIS, James, a distinguished English writer on the subject of grammar, was born at Salisbury on the 20th of July 1709. He received his early education at Salisbury, whence he was removed to Oxford at the age of sixteen; and having passed the usual number of years as a gentleman commoner at Wadham College, he was entered at Lincoln's Inn as a student of law, though not intended for the bar. When he had attained his twenty-fourth year, his father died; and this event having at once freed him from all control, and placed him in the possession of an independent fortune, enabled him to exchange the study of law for other pursuits more congenial to his taste. The decided bent of his mind had always been towards the Greek and Latin classics, which he preferred to every other kind of reading; and to the study of these authors he now applied himself with unremitting assiduity during a period of fourteen or fifteen years. The first fruit of this lengthened course of application was a volume which he published in 1744, containing three treatises; one on Art, another on Music, Painting, and Poetry, and a third on Happiness. These treatises are illustrated with a variety of learned notes and observations; and one of them, that upon Art, has been commended by Lord Monboddo as containing "the best specimen of the dividing or diæretic manner, as the ancients called it, that is to be found in any modern book." But the work by which he is best known is his *Hermes*, a philosophical inquiry concerning universal grammar, which appeared in 1751, 8vo. "Those who would enter deeply into the subject" (of universal grammar), says Dr Lowth, "will find it fully and accurately handled, with the greatest acuteness of investigation, perspicuity of application, and elegance of method, in a treatise entitled *Hermes*, by James Harris, Esq.; the most beautiful example of analysis that has been exhibited since the days of Aristotle." To this eulogium, however, the philosophical grammarians of the present time are not by any means disposed to subscribe. Without questioning the learning displayed in the *Hermes*, we may venture to affirm, that the arrangement of the parts of speech into substantives, attributives, definitives, and connectives, is entirely arbitrary; that nothing whatever is gained by this departure from the ordinary classification, excepting perhaps to impart to the work an appearance of originality, which, upon examination, will be found to vanish; that, though professing to treat the subject of grammar in a philosophical manner, Mr Harris is in reality the slave of authority; and that there is no quality for which his work is less distinguished than that rigid analysis which Bishop Lowth has somewhat hastily given him credit for. This, we think, has been fully established in the article GRAMMAR of the present work, to which accordingly the reader is referred for more ample information. Mr Harris's attention seems to have been first directed to this subject by the *Minerva* of Sanctius, to which he has confessed himself indebted for much valuable information; but it is somewhat remarkable, that with the treatise of Apollonius (*De Constructione Orationis*) also before him, he should not have avoided the narrow and confined views which he has adopted on particular points, or should have missed principles which would have served to guide him through the intricacies in which he is frequently entangled. Mr Harris's other productions are, *Philosophical Arrangements*, published in 1775, being part of a larger work which he had meditated, but did not complete, on the peripatetic logic; and *Philological Inquiries*, printed in 1780, but not published till 1781, containing not so much a regular system, as a summary of the conclusions to which the philosophy of the ancients had conducted them in their critical inquiries. After severe suffering from illness, Mr Harris expired on the 22d of December 1780, in the seventy-second year of his age. In 1801, his son, Lord Malmesbury, published an edition of his works in two volumes quarto; prefixed to which is a biographical sketch of the author from the pen of the editor.

HARRIS, a district of the Outer Hebrides, comprehending the southern part of Lewis, and the small islands surrounding it, of which Bernera, Scalpey, Scarp, Anabich, Tarrinsey, Pabbey, Ensey, and Killigrey, are inhabited. The mainland of Harris is separated from the rest of Lewis by an isthmus about 6 miles across, formed by the harbours of Loch Resort on the W., and Loch Seaforth on the E. coast. It is about 20 miles in length, but of very unequal breadth, being deeply indented by arms of the sea; its general breadth, however, is from 6 to 8 miles. The surface is bleak, rocky, and unproductive; but on the shore are patches of cultivated land, and the valleys afford tolerable pasturage. Pop. of parish or district (1851) 4250.

HARRIS, Sound of, a navigable channel between Harris and North Uist. It is 9 miles in length by from 8 to 12 in breadth, and is studded with rocks, shoals, and islets.

HARRISBURG, a city in the United States of North America, capital of Pennsylvania, and the seat of justice of Dauphin county, is situated on the E. bank of the Susquehanna River, 100 miles W. by N. of Philadelphia. It stands on an elevated plain between the river and Paxton Creek. The state buildings occupy an eminence in the north part of the town. The capitol is an extensive brick building, 180 feet long by 80 feet wide, having a circular portico in front, supported by 6 Ionic columns, and surmounted by a dome. On each side of the capitol is a smaller building, uniform in design, and containing the executive chamber, the state treasury, &c. Harrisburg also contains a state arsenal, county-prison, bank, savings' bank, about twelve churches, Masonic hall, and a Lancasterian school. Among its manufactories are two extensive iron furnaces, a rolling mill, and several breweries and potteries. One daily and eight weekly newspapers are published here. The Pennsylvania railway is here connected with the Lancaster and Harrisburg railway. Harrisburg was founded in 1785, was incorporated in 1808, and in 1812 it became the capital of the state. Pop. (1853) about 8500.

HARRISON, John, the inventor of the gridiron pendulum, an ingenious recoil escapement, and the going fusee, was born in 1693 at Faulby, near Pontefract in Yorkshire. His father was a carpenter, and the son wrought for some time at the father's trade, eking out his gains by occasionally surveying land, and repairing clocks and watches. In 1700 he removed with his father to Barrow in Lincolnshire, and spent much of his time in devising improvements on the machinery of watches. In 1714 government had offered a reward of ten, fifteen, and twenty thousand pounds respectively for a method of determining the longitude at sea within 60, 40, or 30 miles. In 1735 Harrison presented himself before the Board of Longitude at London, with an instrument, which he submitted for inspection to Halley, Grahame, and others. At their instance Harrison was sent in a royal ship to Lisbon to test it, and by it he corrected the reckoning a degree and a half. The commissioners rewarded him with L.500 to enable him to carry on his experiments, which, after some failures, resulted in his producing an instrument so accurate that in the course of a voyage to Jamaica and back it was found to have gone wrong by less than two minutes. Harrison accordingly claimed the reward of L.20,000, which, after a second voyage to Jamaica, and other tests, was finally paid down to him in 1767. Harrison died in 1776 at the age of eighty-two. Till his death he never got over the defects of his early training. He could express himself with perfect clearness and precision on the subject of his art, but, like most uneducated men, he utterly failed when he tried to express his thoughts in writing. This is manifested in his

Description concerning such Mechanism as will afford a nice or true Mensuration of Times. (Hutton's *Math. Dict.; Biog. Brit.;* see also art. Clock and Watch Work.)

HARROGATE, or Harrowgate, a small town and watering-place in the West Riding of Yorkshire, 20 miles W. of York. It is indebted for its rise and importance to its medicinal springs, and is now one of the principal watering-places in the north of England. It consists of two scattered villages, called High and Low Harrogate, situated about a mile from each other, and possessing ample accommodation for visitors. The season commences in May, and continues till September. The springs of Harrogate are both chalybeate and sulphureous. Of the former the oldest is Tewit Well, which was discovered about 1576. The Old Spa, situated on the Stray, was discovered by Dr Stanhope previously to 1631. The Starbeck chalybeate is about midway between Harrogate and Knaresborough. The Saline chalybeate at Low Harrogate was discovered in 1819. The sulphureous springs are the Old Sulphur Wells at Low Harrogate; the Crown Sulphur Well, in the pleasure grounds of the Crown Hotel; and the Knaresborough or Starbeck Spa, nearly halfway between Harrogate and Knaresborough. Harrogate possesses public baths; assembly rooms; reading rooms and libraries; mechanics' institute; and a bath hospital for poor invalids, with accommodation for about 100 patients. Pop. (1851) 3678.

HARROW ON THE HILL, a village in the county of Middlesex, 10 miles N.W. of London. Harrow owes its celebrity to its free grammar school, founded in 1571 by John Lyon, a wealthy yeoman of this parish. The primary object of this school was the gratuitous instruction of boys belonging to the parish of Harrow, but it is now principally attended by sons of the nobility and gentry, and is in high repute as an educational institution. Among the celebrated men who have been educated here may be mentioned Sir William Jones, Dr Parr, Richard Brinsley Sheridan, Lord Byron, and Sir Robert Peel. The number of scholars in 1853 was about 390. It has four exhibitions of 50 guineas each to either university, and two of the same value, founded by the late Mr Sayer, to Caius College, Cambridge. On the summit of the hill on which the village stands is the parish church, surmounted by a tower and spire. Pop. (1851) 4951.

Harrow, an agricultural implement. See Agriculture, vol. ii., p. 272.

HARRY, Blind, or Harry the Minstrel, whose history is an exact modern parallel of the traditionary account of Homer, flourished in the fifteenth century. All that is known of him (and it is very little) is derived from Major the historian, who says of him—"Henry, who was blind from his birth, composed in the time of my youth the whole book of William Wallace, and embodied all the traditions about him in the ordinary measure, in which he was well skilled. By the recitation of these in presence of the great, he procured, as indeed he deserved, food and clothing." Blind Harry's work is in eleven books, and contains a great many animated and picturesque descriptions, especially of war and battle pieces. Sir Walter Scott turned his knowledge of Blind Harry to good account; though he does not seem to have attached the same importance to it as to Barbour's *Bruce*.

HART, a stag in its sixth year. See Mammalia.

HARTE, Walter, the historian of Gustavus Adolphus, was born about the beginning of the eighteenth century. He was educated at Marlborough School, and afterwards at Oxford, where he graduated in 1720. He early enjoyed the friendship of Pope, who is said to have contributed largely to his *Essay on Satire*, 8vo., 1730; and to his *Essay on Reason*, fol. 1735. He afterwards became vice-principal of St Mary Hall, and, through the influence of Lord Chesterfield, to whose natural son he had been tutor from 1746 to 1750, canon of Windsor. In 1759 he published his History of Gustavus Adolphus, in two vols. 4to. This work, though devoid of order, and harsh and pedantic in style, yet exhibits great research and great ability. Harte, who is said to have been a man of excessive vanity, left London on the day of the publication of his book, that he might be out of the way of the great praise it was to receive; and he was ashamed to return when he found how very ill it had succeeded. His only other productions are some Sermons, and the *Amaranth*, a poem which, as he informs us, was written for his private consolation under a lingering and dangerous state of health, and which is marked by a very serious cast of feeling. He died at Bath in 1774.

HARTFORD, a city in the United States of North America, capital of Hartford county, Connecticut. It stands on the right bank of the Connecticut River, at the head of the sloop navigation, and 112 miles N.E. of New York. It is connected with East Hartford on the opposite side of the river, by a covered bridge 1000 feet in length. The city is for the most part compactly built, principally of brick and freestone. The state house, erected in 1792, is a Doric edifice, with two porticos, and a dome from which a magnificent view of the city and surrounding country is obtained. Besides the legislative halls, it contains apartments for the several courts of the state and county, and numerous public offices. Hartford is the semi-capital of the state, the legislature meeting alternately here and at New Haven. The city hall fronting the market square is a handsome Grecian building. There were here in 1852 twenty-one churches of various denominations, many of them large and elegant edifices. The educational and literary institutions are numerous and important. Trinity College, an Episcopalian institution, founded in 1824, has about eighty students, and a library of 15,000 vols. The Wadsworth Athenæum is an elegant granite edifice in the Gothic style, having apartments for the Connecticut Historical Society, with its library of 5000 vols., ancient documents and MSS., and valuable collection of historical relics; the Young Men's Institute, with lecture room, and library of about 10,000 vols.; a picture gallery, &c. The American asylum for the deaf and dumb, the first institution of the kind in the United States, was organised in 1817 by the late Rev. T. H. Gallaudet, LL.D. The average number of pupils is about 200. The lunatic asylum, founded in 1822, had during the year ending April 1, 1853, 321 patients. Hartford is situated on the great line of railways connecting the New England with the Middle, Southern, and Western States, and also on the line of the Providence, Hartford, and Fishkill railway. The more important articles of manufacture are railway carriages, fire-arms, and hardware. The value of its manufactures for year ending June 1850 was about L.723,878. The city is divided into six wards, and is governed by a mayor, elected biennially, six aldermen, chosen annually, and a common council of twenty-four members, also chosen annually. Hartford was permanently settled in 1635; but previous to that time the Dutch had explored the Connecticut, and erected a fort on what is still called Dutch Point in the S.E. part of the city. It was created a city in 1784. Pop. (1850) 17,966, estimated in 1853 at about 22,000.

HARTLAND, a market-town of England, county of Devon, 46 miles W.N.W. of Exeter. It is about 2 miles from the Bristol Channel, where there is a landing quay lying under the cliffs, much frequented by fishing vessels. The parish church stands about a mile from the town, near the sea. The inhabitants are chiefly employed in fishing or in agriculture. Of Hartland Abbey (founded by Githa, wife of Earl Godwin) some portions of the cloisters still remain. Market-day, Saturday. Pop. of parish (1851), 2183.

HARTLEPOOL, a seaport and market-town of England, county of Durham, a few miles N. of the mouth of the River Tees, and 17 miles S.E. of Durham. It stands on a small peninsula, jutting out into the sea, and formed partly by a pool called the Slake, which is dry at low water. The Normans called the place Hart-le-pol (the pool or slake of Hart), whence the modern name. A monastery, which is mentioned by Bede, was founded here at a very early period. Hartlepool is mentioned as a harbour of some consequence as early as 1171. In the thirteenth century it belonged to the Bruces of Annandale, in Scotland, the progenitors of the royal family of that name. It was erected into a borough by John, A.D. 1200. When Bruce declared his pretensions to the Scottish crown his English possessions were forfeited, and Hartlepool was granted to the Cliffords, in whose possession it long remained. It suffered severely from the Scots in 1312, and again in 1315, a year after the battle of Bannockburn. It was seized by the insurgents in the northern rebellion under the Earls of Northumberland and Westmoreland, in the time of Elizabeth. During the civil war it was taken by the Scottish army in 1644, and retained by them till 1647. Hartlepool was, during the thirteenth century, fortified by walls, which inclosed it on every side except on the east, where it was sufficiently protected by high cliffs. Considerable portions of these walls still remain. The old haven is now disused. The present harbour—formed by a pier run out on the south side of the town—is easily accessible in rough weather to laden vessels under 100 tons. Extensive docks have recently been constructed here. One, opened in 1847, contains 8 acres; and another, opened in 1852, contains 14 acres. The harbour has also been enlarged from 13 to 44 acres; and plans have been made for two more large docks, should the trade require it. A graving dock has also been formed at the west end of the new dock, capable of containing a vessel of the largest class. Hartlepool thus enjoys great facilities for trade, which its extensive railway connection opens up to it. Its coal trade is very great; fishing is extensively carried on; and it is much frequented in summer for sea-bathing. The vessels registered as belonging to the port on 31st Dec. 1854 were:—Under 50 tons—sailing, 2, tonnage 30; steam 4, tonnage 88: above 50 tons—sailing 164, tonnage 35,210; steam 3, tonnage 1080. The vessels that entered and cleared at the port in 1854 were:—Coasting trade, inwards, sailing vessels 368, tonnage 29,264; steam 2, tonnage 42: outwards, sailing vessels 6256, tonnage 827,926; steam 51, tonnage 20,604. Colonial trade, inwards, sailing vessels, British 25, tonnage 4281; foreign 8, tonnage 1054: outwards, British 91, tonnage 17,088; foreign 24, tonnage 10,570. Foreign trade, inwards, sailing vessels, British 399, tonnage 72,056; foreign 696, tonnage 79,135: steam vessels, British 55, tonnage 17,119; foreign 1, tonnage 235: outwards, sailing vessels, British 540, tonnage 100,653; foreign 1543, tonnage 166,898: steam vessels, British 53, tonnage 16,521; foreign 1, tonnage 235. Pop. (1851) 9503.

HARTLEY, a township and small seaport of England, county of Northumberland, 4 miles S.S.E. of Blyth. The harbour, about half a mile from the town, is accessible to vessels of 300 tons. A colliery, and glass and bottle works, afford employment to most of the inhabitants. Pop. of township (1851), 1627.

HARTLEY, DAVID, the celebrated author of the *Observations on Man*, was born August 30, 1705, at Armley, in Yorkshire. His father was a clergyman, and he was himself destined for the church, but, after graduating at Cambridge, and becoming a fellow of Jesus College, he changed his views, and studied medicine. He practised as a physician successively at Newark, Bury St Edmunds, London, and Bath, where he died, Aug. 25, 1757, in the fifty-third year of his age. He was twice married, and had issue by both his wives. His character, as delineated by one of his own children, is so interesting, that we give the extract entire:—"From his earliest youth his mental ambition was pre-occupied by pursuits of science. His hours of amusement were likewise bestowed upon objects of taste and sentiment. Music, poetry, and history, were his favourite recreations. His imagination was fertile and correct, his language and expression fluent and forcible. His natural temper was gay, cheerful, and sociable. He was addicted to no vice in any part of his life, neither to pride, nor to sensuality, nor to intemperance, nor ostentation, nor envy, nor to any sordid self-interest; but his heart was replete with every contrary virtue. The virtuous principles which are instilled in his works were the invariable and decided principles of his life and conduct." All extant records of the great philosopher agree in the main with this account of one who had the best means of knowing and appreciating his private worth. It is no wonder that the society of such a man should have been courted by the leading thinkers and writers of that time, as we know it to have been by Law, Butler, Warburton, and Hoadley (all bishops), Jortin, Young, Hooke, and many others. Hartley began the composition of his great work when he was twenty-five years of age; and, after working on it for sixteen years, published it, after certain delays, in 1748, in 2 vols. 8vo. It was republished in 1791, with notes and additions translated from the German of H. A. Pistorius, and a sketch of his life by his son. The *Observations on Man* are very fully discussed in the SECOND PRELIMINARY DISSERTATION (pp. 378 to 386), by Sir James Macintosh, prefixed to this work.

HARTSHORN, SPIRIT OF, a volatile alkali of a very penetrating odour, and an efficacious remedy in nervous affections. It is an impure ammonia, and derives its name from the deer's horns from which it was formerly prepared, and to which very wonderful medicinal virtues were ascribed; but it is now obtained by the destructive distillation of bone of any kind. The *salt of hartshorn*—an impure solid carbonate of ammonia, formed at the same time—is sometimes used as a remedy in fever. Under the name of *hartshorn shavings*, the scrapings or raspings of deers' horns are variously employed in medical practice. Deers' horns, when boiled in water, yield a strong and very nutritive jelly, though inferior, perhaps, to that afforded by ivory.

HARUN AL RASCHID, the famous Caliph of Bagdad, holds in oriental history very much the same place that his contemporary, Charlemagne, holds in the history of Europe. His love of peace and justice, of literature and the arts, was only equalled by his skill and success in war. His reign is the golden age of the Mohammedan dominion, and furnished the materials for some of the best stories in the *Arabian Nights*. He died in 808, after a reign of twenty-two years. See BAGDAD.

HARUSPICES, an order of priests among the Romans. Their name is derived, according to Donatus (Ter. *Phorm.* iv. 5), from *haruga*, a victim, though others have referred its origin to the word *ara*, an altar. Dionysius (ii. 22) explains it as a corruption of the Greek word ἱεροσκοπος, *inspector of the victims*, and states that Romulus appointed three, one from each tribe. This number was gradually increased, till it became an important body in the state, was regarded as a collegium, and its president was called Summus Haruspex, or Magister Publicus. In the flourishing period of the republic it enjoyed great influence from the explanation it was called on to give of omens, which were taken at the commencement of any important undertaking; but in proportion as the doctrines of the Greek philosophers spread amongst the Romans, the Haruspices gradually lost their influence, at least amongst the higher ranks. Cato used frequently to say that he was surprised the Haruspices did not laugh when they met one another in the street. (Cic. *Nat. Div.* i. 26.) The Emperor Claudius made an attempt to revive their importance, and the Pontifices received an order to report as to the best way of accomplishing this object; but how far he succeeded we have no means of discovering. (Tacit. *Ann.* xi. 15.) Alexander Severus appointed fixed salaries to the members of this body, and teachers, who should instruct the young in the arts of soothsaying (Lamprid. 44); and they continued in this state till Constantine put an end to their functions, by forbidding, under the penalty of death, the continuation of their superstitious practices. (Codex Theodos. 9, tit. 16.) The duties of the Haruspices were to examine the entrails of victims sacrificed, and thence to derive omens of futurity. They also attended to the flame, the smoke, whether the victim came to the altar willingly, stood quietly, fell by one stroke, and many other circumstances of the same kind. Their knowledge of this art was derived from the Etruscans; and in early times the young nobility used to be sent to Etruria to be instructed in this art. (Cic. *Div.* i. 2, 41.)

HARVEST (probably from a Saxon word signifying *herb feast*), that season of the year when the corn is reaped and gathered into barns.

HARVEY, WILLIAM, the discoverer of the functions of the heart, and of the mode of circulation of the blood, was born at Folkstone, in Kent, on the 1st April 1578. He was the eldest of seven sons and two daughters. His father, a Kentish "yeoman," must have been in some degree wealthy, as his sons were brought up to pursuits for the successful practice of which capital is necessary. Five of the younger brothers were Levant merchants of wealth and standing in the city of London. John, the second son, was attached to the court as king's footman, was one of the king's receivers for Lincolnshire, and sat in Parliament as member for Hythe; and William, the eldest, went to Cambridge to be educated for the practice of physic.

At the age of ten years Harvey went to the grammar-school at Canterbury, where he was doubtless initiated into a knowledge of the Greek and Latin languages. He remained there five or six years; and at the age of sixteen was entered a pensioner of Caius' College, Cambridge, the 31st May 1593. At nineteen he took his B.A. degree, and left Cambridge to study medicine at the University of Padua, then of wide celebrity as a medical school. Here he had the advantage of cultivating the medical sciences under the ablest masters of the day, inasmuch as amongst the eminent men there congregated were the celebrated Fabricius of Aquapendente, Julius Casserius, and J. T. Minadorus. To the first-mentioned Harvey doubtless owed his philosophic spirit of inquiry, and that inductive method of research which led him to the greatest discovery in physiology.

Having passed five years at Padua, Harvey, then aged twenty-four (1602), graduated as doctor of medicine, and received his academic authority to practise and to teach his science and art. In the same year he returned to England, and graduated again in his own University of Cambridge. His next step was to commence practice, and settle for life. To these ends he took up his residence in London, and married the daughter of Dr Lancelot Brown, a physician of the day. In both these steps he was probably guided by a wise discretion, feeling assured that a professional father-in-law, and five brothers, influential and esteemed city merchants, would be valuable aids to him in getting into practice. He was now in his twenty-sixth year.

Harvey's connection with the Royal College of Physicians of London seems to date from the earliest period of his professional career, for his name is on the roll of candidates for the fellowship of the college in 1604; and three years afterwards (1607) he was duly admitted a fellow of the college.

In the beginning of 1609, the health of Dr Wilkinson, physician to St Bartholomew's Hospital, beginning to fail, Harvey, being in his thirty-second year, sought the reversion of the office, as was then customary, and in support of his application brought forward testimonials of fitness from the president of the College of Physicians, Dr Adkinson, and "diverse others doctors of the auncientest" of the college, together with the king's letters commendatory. His application was granted, and Dr Wilkinson having died in the course of the year, he was formally elected to the vacant office (which he filled for thirty-four years), on the 14th October 1609. At the time of his election, the steward of the hospital was bound under an obligation to Harvey for a debt of L.52, 10s., due to his brother John, at that time attached to the court, and had law proceedings taken against him for the recovery of the money.

From this time may be dated Harvey's rise to distinction. In 1615 he was appointed to deliver the course of lectures on anatomy and surgery at the College of Physicians founded by Dr Richard Caldwal, and in the month of April of the following year fulfilled the duties of his office. It is generally thought that in this first course he presented an exposition of his views of the circulation of the blood, and which continued to be one of the subjects of the lectures on anatomy which he delivered for several successive years at the college. It was not, however, until the year 1628 that he published, at Frankfort, in 4to, his *Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus*, dedicating it to the king.

About this time he must have become connected with the court more closely as physician-extraordinary to James I., an office he filled during the remainder of that monarch's reign. Five or six years after his death (1632) he was appointed physician to his successor, Charles I. Previously to this, 1630, he had been sent by the king to travel with the Duke of Lennox, at which time he resigned the office of treasurer to the Royal College of Physicians.

Charles I. gave his royal patronage to Harvey's scientific researches, as well as to his practical skill. He seems to have taken great interest in the former, for he had several demonstrations made before him by Harvey of the *punctum saliens* in the embryo chick and deer, and to have shared Harvey's anatomical researches on the does he placed at the disposal of the latter.

From this time Harvey's movements were closely connected with those of the court. In 1633 he accompanied Charles on his journey into Scotland, and in 1636 he went with Thomas Howard, Earl of Arundel, whose physician he was, on his embassy extraordinary to the Emperor of Germany. It was on this occasion that, in May of this year, he gave a public demonstration of the circulation at Nuremberg, to satisfy the doubts of the distinguished Professor of Nuremberg, Casper Hoffmann, but who, however, remained incredulous. In 1639 he accompanied Charles on his first hostile expedition into Scotland, and again in the following year. He was also present with his king at the battle of Edgehill. During the fight he had the prince and the Duke of York entrusted to his care, and he told Aubrey that he withdrew with them under a hedge, and took a book out of his pocket to read; but he had not read very long before a bullet of a great gun grazed on the ground near him, and made him remove his station.

After the battle of Edge-hill, Harvey went with the king to Oxford. Here he busied himself with his researches into generation; for Dr George Bathurst of Trinity College had a hen to hatch eggs in his chamber, which he and Harvey opened daily. He was received and entertained at Oxford with great distinction, and honoured with the degree of M.D. In 1645 he was made warden of Merton College, in place of Sir Nathaniel Brent, who had left his college to join the popular party. In the following year Oxford surrendered to the parliamentary forces, and Brent was reinstated. While Harvey was at Oxford a motion was made in the House of Commons, February 12, 1644, for the appointment of Dr Micklethwayte as his successor in the office of physician to St Bartholomew's Hospital, on the ground that Harvey had "withdrawn himself from his charge, and is retired to the party in arms against the Parliament."

Harvey.

Harvey returned to London in 1646, after the surrender of Oxford, and seems to have followed the fortunes of his king no longer. He was now sixty-eight years old, and had little taste, doubtless, for the varied fortunes of civil broil. His wife was probably still alive, and to her repose would be grateful; and having no children he seems to have avoided the responsibilities of house-keeping by having his own apartments furnished with his own furniture at the houses of two of his surviving brothers, Eliab and Daniel. In 1649 (if Aubrey's statement is to be believed) he visited the Continent, travelling as far as Italy, accompanied by his friend, Dr Ent, an accomplished physician and scholar. In the beginning of 1651 he published his second great work—namely his *Exercitationes de Generatione Animalium*, 4to, London. The year after, when Harvey was looked upon by common consent as the most distinguished anatomist and physician of the age, the College of Physicians placed a statue of him in their hall, with the following inscription:—

GULIELMO HARVEIO
VIRO MONUMENTIS SUIS IMMORTALI
HOC INSUPER COLLEGIUM MEDICORUM LONDINENSE
POSUIT.
QUI ENIM SANGUINI MOTUM
UT ET
ANIMALIBUS ORTUM DEDIT.
MERUIT ESSE
STATOR PERPETUUS.

About this time Harvey commenced a handsome addition to the college buildings, comprising a common hall and library, the latter of which he furnished with books. In 1654 he was elected to the chair of president of the College of Physicians, but declined to serve on the ground of his age and infirmities. He continued, however, to deliver his lectures till within a year or two of his death. He died on the 3d June 1657, of paralysis, having completed the eightieth year of his age.

Harvey was a ripe and finished scholar, and an inductive philosopher of a class as high as his illustrious contemporary and patient, the Lord Chancellor Bacon. He was acquainted with all the men of letters and of science of his day—Hobbes, Boyle, Dryden, Cowley, &c.; and although the treatment he experienced by his contemporaries has often been quoted by empirics as an instance of the martyrdom which men of genius and of original views have to encounter, it does not appear that his views were met with any unusual hostility from the great body of the learned. It is true one or two foreign anatomists indulged in some foolish abuse; and, if we may believe Aubrey's tattle, he "knew several practitioners in this town that would not have given threepence for one of his bills [prescriptions]; and that a man could hardly tell by his bills what he did aim at." But, in opposition to this gossip, we have it on record that Harvey was not only physician to the Court, but also had the confidence of many of the most distinguished among the nobles and men of eminence of the time. He lived to see his discoveries universally acknowledged, and to be deeply revered by his brethren.

His moral character was of the highest, and may be judged of by what he has himself enjoined on the College of Physicians. Having endowed it handsomely with his paternal estate, he left funds for a meeting and collation once a month, and for a general annual feast of all the fellows, at which should be delivered an oration in commemoration of the benefactors to the college, and "an exhortation to the members to study and search out the secrets of nature by way of experiment, and for the honour of the profession to continue mutually in love." The College of Physicians of London would have enjoyed a fairer fame, and British medicine a higher reputation, if that body had more faithfully followed the example and written precepts of their immortal benefactor. Harvey had refined feelings and a strong sense of duty. He returned not railing for railing when he encountered his depreciators in controversy. He was faithful to his sovereign, devoted to science, sedulous for the advancement of his profession, munificent to his college, kind and considerate to his relatives. The public voice of his day fully acknowledged his merits, and its verdict has never been questioned. (T. L.)

Harwich
||
Haslingden.

HARWICH, a municipal and parliamentary burgh and seaport town of England, county of Essex, on the extremity of a tongue of land projecting into the estuary of the Stour and Orwell, 15 miles N.E. of Colchester. It consists of three principal streets, well paved and lighted with gas. The church of St Nicholas is a large brick edifice, in the perpendicular style, with stone buttresses and steeple, erected in 1821. There are also chapels for Independents, Wesleyan-Methodists, and Baptists; a grammar school; town-hall; gaol; theatre; assembly-rooms; baths; and custom-house. Shipbuilding and the fisheries are extensively carried on; and Roman cement is largely manufactured from a stone dredged at the mouth of the harbour. In summer it is much frequented for sea-bathing. The harbour is one of the best on the E. coast of England, being at once safe and capacious, and having water sufficient to float the largest ships of war. The entrance is, however, encumbered with rocks, and dangerous without a pilot. It is marked by two lighthouses, and is defended by a strongly-garrisoned fort and battery. It has been made a harbour of refuge. On 31st December 1854, the vessels registered as belonging to the port were—under 50 tons, 66, tonnage 1974; above 50 tons, 53, tonnage 5068. During that year 519 vessels of 37,069 tons entered, and 425 of 19,896 tons cleared, in the coasting trade; 1 vessel of 28 tons entered, and 11 of 535 tons cleared, in the colonial trade; and 70 vessels of 5869 tons entered, and 169 of 9494 tons cleared, in the foreign trade. Harwich is governed by a mayor, 4 aldermen, and 12 councillors, and returns 2 members to parliament. Pop. (1851) 4451.

HARZ, or Hartz Mountains, the most northerly range in Germany, run E.S.E. and W.N.W., between N. Lat. 51. 30. and 52., and E. Long. 10. and 11. 30. They are 55 miles long by 19 broad, and cover an area of above 1000 square miles. The water-shed between the basins of the Weser and the Elbe divides the whole range into two parts; the eastern is called the Lower Harz, and the western the Upper Harz. The range exhibits a collection of irregular heights, chiefly covered with pine; on the Lower Harz are also found ash, elm, oak, and beech. The chief summit is the Brocken or Blocksberg, 3740 feet above the level of the sea. Snow lies upon the higher parts of the range during eight months of the year. The chief mineral district is the Upper Harz; it contains lead, silver, and copper mines, affording work for between 15,000 and 20,000 labourers annually. Geologically, the Harz mountains consist of granite and mica slate, which underlies graüwacke, clay-slate, limestone, gypsum, &c.

HARZGERODE, a town of Central Germany, duchy of Anhalt-Bernburg, 7 miles S.W. of Ballenstedt. It has an old castle, built in 1552, and a forest school. In the vicinity are silver, copper, vitriol, and iron-works, including the Victor Frederick silver-works, and the Magdesprung iron-works. Pop. 2500.

HASLEMERE, a small town of England, county of Surrey, 8 miles S.S.W. of Godalming. It is an ancient borough, and, previous to the passing of the Reform Act, by which it was disfranchised, it returned two members to parliament. The parish church is an ancient edifice with a low square tower. Pop. of parish (1851) 955.

HASLINGDEN, a market-town of England, Lancashire, 7 miles S.E. of Blackburn. Part of it stands on the slope, and part at the foot of a hill; the latter being the newer portion. The houses are mostly of stone. The parish church is a large and handsome edifice of modern date, with the exception of the tower, which belonged to a previous building. It contains a fort of the time of Henry VII., as well as several monuments. There are chapels connected with Independents, Methodists, and other dissenting bodies; national and other schools; and a mechanics' institute with library. The woollen manufacture was till lately the staple of the town, but it has now in a great measure been superseded by that of cotton. The silk manufacture is also carried on here. In the vicinity are quarries of building stone and slate, and several coal mines. Market-days, Wednesday and Saturday. Pop. (1851) 6154.

HASSELQUIST, Frederic, a Swedish naturalist, and one of the most distinguished of all Linnæus' pupils, was born in 1722, at Taern-Valla, in E. Gothland. His father, who was vicar of the parish, died, leaving his family quite unprovided for; but a kind uncle had the young Hasselquist educated with his own children. After the death of this good friend, he was sent in 1741 to the university of Upsal, where his taste for the study of nature was fostered and developed by Linnæus. In 1747 he published an essay, *De Viribus Plantarum*, in which with equal boldness and ability he exposed the popular ideas of the medical virtues of many plants, and defended the old but then discarded doctrine of "like forms, like virtues." It is to this defence of Hasselquist's that the doctrine in question mainly owes the steady foot-hold it has ever since his day maintained. His scientific abilities, backed by the influence of Linnæus, now procured for him one of the scholarships for enabling students to travel, and Hasselquist set out for the Holy Land, the natural history of which was at that time very imperfectly known. After visiting part of Asia Minor, Egypt, and Palestine, he turned his face in the direction of home; but his constitution, naturally weak, gave way under the fatigues and anxieties of travel, and he died at Smyrna, Feb. 9, 1752, at the early age of thirty. His collections reached home in safety, and, five years after his death, the results of his wanderings in the east were published by Linnæus under the title of *Iter Palestrinum*, a work which contains a world of information on almost every department of the natural history of the countries visited by Hasselquist, and which has not even yet been superseded as a book of reference. The work is divided into two parts, the first consisting of the traveller's journal and letters, and the second of his remarks on the botany, zoology, and mineralogy of the countries he passed through, with observations on the prevalent diseases and their cure, and the state of industry, commerce, and the arts. The amount of genuine and solid labour and ability displayed in this work will prevent it from ever being totally superseded. Its author's name is consecrated in his favourite science by having been given to the *Hasselquistia cordata*, an oriental umbelliferous plant of the order of Apiaceæ. His travels were translated into English in 1766.

HASSELT, a town of Belgium, capital of the province of Limburg, on the Demer, 15 miles W.N.W. of Maestricht. It is the seat of the principal provincial courts, and is tolerably well built. It has several churches and chapels; a court-house, 2 hospitals; almshouse; college; and several primary schools. The chief manufactures are linen, leather, tobacco, gin, beer, and salt. It is likewise a place of considerable trade. Pop. of commune (1851) 9784.

HASTA, or *Hasta Pura*, among medallists, a headless spear, or rather a long kind of sceptre, occasionally given to all the heathen deities. The *hasta pura* is supposed to be a symbol of the goodness of the gods, and of the conduct of providence, which is equally mild and forcible.

HASTATI. See Army; § *Roman Army*, vol. iii.

HASTINGS, a parliamentary and municipal borough and market-town of England, county of Sussex, 64 miles from London by the road, and 74 by the Hastings branch of the South-Eastern railway; in official proceedings ranks as the first of the Cinque Ports. Hastings lies on the sea-coast at the mouth of the Bourne, a small stream which intersects the town. An amphitheatre of hills and cliffs shelters it on every side except the S., where it lies open to the sea. Its climate is thus both mild and equable, and annually attracts a large number of invalids. During the bathing season great crowds of visitors flock to the town, for whose comfort every provision has been made in the shape of hotels, libraries, baths, and promenades. The town originally consisted of two main streets, separated by the Bourne, but since it became a favourite summer resort many handsome streets and squares have been added to it. It has also been lighted with gas and paved, and the sewerage, at one time notoriously bad, has of late been much improved. The principal public buildings are the ancient parish churches of All Saints and St Clements, the town-hall, custom-house, and gaol. There are also chapels belonging to the Roman Catholics, Baptists, Independents, Methodists, and other sects. Besides two endowed schools, there are British, national, and infant schools. The permanent residents in the town are chiefly engaged in fishing and boat-building, in both of which they are reputed to have much skill; but much of the prosperity of Hastings now depends on the influx of summer visitors. Of late years these have so much increased in number that for their accommodation houses have been built over the whole ground extending between Hastings and the little town of St Leonards. A few years ago, St Leonards was only a small village about a mile distant from Hastings, but it is annually increasing with great rapidity, and as its population is included in that of its larger neighbour, it is now considered as forming a part of it. The most striking part of the town is the Marina, a handsome street with a covered colonnade looking towards the sea. The united parades of Hastings and St Leonards are not surpassed, if indeed they are equalled, by any other sea-walks in England. The scenery in the neighbourhood of the town is charmingly picturesque. Among the places of interest in the vicinity may be mentioned Bulverhithe, where William the Conqueror landed from France; the ruins of the old fortress on the high cliffs overhanging the town on the W.; and Battle Abbey, which, though it takes its name from the fight of Hastings, is 7 miles distant from the town. (See Battle.) The corporation consists of a mayor, 6 aldermen, and 18 councillors. The borough returns two members to parliament. Pop. of parliamentary borough (1851), 17,011; of municipal, 16,966; number of registered electors, 976.

HASTINGS, Warren, the real founder of the English empire in Hindustan, was a scion of an old and noble but impoverished family of Worcestershire, and was born Dec. 6, 1732. The best part of his education he got at Westminster School, where he had Vincent Bourne for his teacher, and Churchill, Colman, Lloyd, Cumberland, and Cowper among his school-fellows. Though he was the cleverest lad of his standing, and would infallibly have distinguished himself at the university, it was determined that he should begin life for himself without delay; and interest having been made on his behalf he obtained a writership in the service of the East India Company, then beginning to struggle into existence. His first residence in India lasted for fourteen years. He went out in 1750, and he returned home in 1764. During that period he was sometimes engaged on diplomatic missions into the interior, but most of his time was spent in commercial enterprises. His opportunities of displaying his abilities were consequently few; and though he did not then attain any high rank in the service, he was silently educating himself for the great destiny that awaited him. He made himself a thorough master of the Persian and Hindustani languages, and probed to their subtlest depths the characters of the people that spoke these tongues. To this knowledge of their languages and themselves Hastings owed in great measure his power over the natives, and the final triumph of his administration. At the close of the fourteenth year of his service, Hastings returned home with a fortune so very small and so unlike those that were then made in India, that nothing more is required to prove that he must have been strictly just in his dealings with the natives. His desire was to spend the remainder of his days in the calm retirement of home, but partly by over-liberality to his relatives, and partly by mismanagement of his own, his little fortune melted away altogether; and at the end of four years he was glad to return to India, with the appointment of member of council of Madras. Three years later he exchanged this subordinate office for the chief-magistracy of Bengal, from which in 1774 he was promoted to the governor-generalship of British India. It was not long before he was called upon to show what was in him. The struggle upon which he now entered, and from which in the end he came forth a victor, was begun, not for conquest but for existence; and this, though it is far from excusing, at least palliates the extreme measures to which he had recourse. The conquests of Clive, though they had greatly extended the territorial limits of the Company's possessions, were a source of weakness rather than strength, for they had not yet been consolidated, and from their position served as a tempting bait to the cupidity of the famous Hyder Ali, the able and daring rajah of Mysore. To baffle this dangerous antagonist, and the alliances which he formed in the East; to out-manœuvre the tactics of his colleagues at the council-board, who hated and did their best to thwart him; to carry on the internal administration; and, above all, to remit regular dividends to England—to do all this, and at the same time maintain even the semblance of fair and scrupulous dealing, was plainly beyond mere human powers. It was no wonder, then, that rumours grew rife in England of cruelty, tyranny, and extortion carried on to an extent that made the blood run cold to hear of; and as little wonder that the directors of the Company were afraid to stem the tide of public opinion that ran so strong against the man to whom they owed the most part of their wealth and power. But all their anxiety to procure his removal was unable to move the proprietors, on whose support Hastings calculated in all his subsequent career. His conduct was now marked by an obstinate spirit of independence. He did not scruple to disobey the orders sent from England; reduced his refractory colleagues to silence or assent; and, with the title of a servant, swayed really a more despotic and irresponsible power over a greater population and a wider extent of country than any sultan or rajah in the Indian peninsula. In 1785 he resigned his high office and returned home. He was well aware that he would be called upon to give an account of his stewardship, and he did not shrink from the result. His trial is the most memorable in the annals of modern jurisprudence. Proceedings began in the session of 1786, and were not brought to an end before the spring of 1795. The serious business of the impeachment was entrusted to Burke, who was supported in the conduct of the case by the most eminent Whig notabilities of the day, Fox, Grey, Sheridan, and others. The counts of the indictment were finally reduced to four,—the oppression and final expulsion of the rajah of Benares; the maltreatment and robbery of the Begums of Oude; the acceptance of presents of immense value; and connivance at unfair contracts and reckless expenditure of the public revenues. The prosecution was opened by Burke in a speech of extraordinary eloquence and power, which extended over three days. He was succeeded by Fox, who in his turn gave place to Sheridan. The speech of that brilliant wit was said by the ablest among those who heard it to have been the best that was ever delivered in the English House of Commons. It certainly was one of the most telling, for it caused so much excitement that no other speaker could obtain a hearing, and the debate was adjourned. Other speakers took up the cue, and the prosecution extended over the entire sessions of 1788, 1789, and 1790, engrossing no fewer than 72 days. The defence was longer still, and was skilfully protracted till April 17, 1795, on which day the accused was acquitted by an overwhelming majority. An acquittal had been expected, and the voice of the nation approved it. The defendant had come before his judges, well aware that the feeling against him was strong. He now left the bar of the Lords with an equally unreasonable feeling in his favour. It was believed that his accusers had, of set purpose, retarded the course of justice, though by far the larger share of the blame or merit of the delay was due to Hastings himself, who foresaw the reaction in the public mind which eventually took place. He was now regarded as an oppressed and persecuted man, and therefore an object of sympathy and compassion. The bitter invective of which the prosecutors made so liberal a use was adduced to prove that their hostility was that of personal and malignant rancour. The expenses of the case were enormous. This defence cost Hastings upwards of L.76,000, and he had sworn in his trial that at no period had he ever been worth more than L.100,000. His friends of the India House felt that his claims upon them were strong, and proposed to settle on him an annuity of L.5000. Some delay occurred in passing this proposal, and Hastings was reduced to such straits that he could hardly pay his weekly bills. His allowance was at length fixed at L.4000 a-year, and the company lent him L.50,000 more for 18 years free of interest. This ought to have sufficed for the ex-governor to live in luxury, but he was a bad manager, and he had frequently to apply to his old supporters for aid, which was always liberally granted. The last 24 years of Hastings' life were spent at Daylesford, in Worcestershire—an estate which had been lost to the family by the unthrift of his ancestors, and which, from his earliest years he had determined to regain. He amused himself with embellishing his grounds, and endeavouring to naturalize in England some of the animals and vegetables of India. The peerage, which he not unnaturally looked for as the reward of his services, and of which it was said that the patent had even been made out, was from some unexplained cause or other withheld, and Hastings never rose beyond the rank of privy-councillor, to which he was raised shortly before his death, which happened Aug. 22, 1818, when he was in his eighty-sixth year. It was proposed that he should be buried in the abbey of Westminster, but permission was refused; and his dust was consigned to its last resting-place in the chancel of the parish church of Daylesford, in earth which already held the bones of many chiefs of the house of Hastings. "On that very spot, probably," writes the most eloquent chronicler of his strange career, "four-score years before, the little Warren, meanly clad and scantily fed, had played with the children of ploughmen. Even then his young mind had revolved plans which might be called romantic. Yet, however romantic, it is not likely that they had been so strange as the truth. Not only had the poor orphan retrieved the fallen fortunes of his line; not only had he repurchased the old lands, and rebuilt the old dwelling;—he had preserved and extended an empire; he had founded a polity; he had administered government and war with more than the capacity of Richelieu; and had patronized learning with the judicious liberality of Cosmo. He had been attacked by the most formidable combinations of enemies that ever sought the destruction of a single victim; and over that combination, after a struggle of ten years, he had triumphed. He had at length gone down to his grave in the fulness of age—in peace, after so many troubles; in honour, after so much obloquy."

Those who look on his character without favour or malevolence will pronounce that in the two great elements of all social virtue—in respect for the rights of others, and in sympathy for the sufferings of others—he was deficient. His principles were somewhat lax. His heart was somewhat hard. But while we cannot with truth describe him as either a righteous or a merciful ruler, we cannot regard without admiration the amplitude and fertility of his intellect; his rare talents for command, for administration, and for controversy; his dauntless courage; his honourable poverty; his fervent zeal for the interests of the state; his noble equanimity, tried by both extremes of fortune, and never disturbed by either.

(*Essay on Warren Hastings*, by T. B. Macaulay; *Memoirs of the Life of Warren Hastings*, by G. R. Gleig, M.A.; Mill's *History of British India*, which last contains a very full and impartial statement of Hastings' case, and able summing up of the evidence of both sides, and a sentence qualified, yet, on the whole, favourable to him, who, as he was the first, was also the ablest of all the men to whom the destinies of our great empire in the East have ever been entrusted.)

HAT is a term of Saxon derivation, from *haet*, a cover for the head. It is sometimes called *castor*, from its being made of the fur of the castor or beaver. As a piece of dress, the period of its introduction is not certain, although it may with great probability be referred to the early distinctions of Roman Catholic dignitaries. Froissart chronicles, that it was "saide to the cardynals, Sirs, advyse you if ye delyvere us a Pope Romayne, we be content, or els we woll maike your heddes reeder than your hattes be;" from which, and from many other documents, it appears that at this period, as well as for some centuries after, hats were generally of a scarlet or red colour, and made of "a fine kinde of haire matted thegither." A "hatte of biever," about the middle of the twelfth century, was worn by some one of the "nobels of the lande, mett at Clarendom;" and Froissart describes hats and plumes which were worn at Edward's Court in 1340, when the Garter order was instituted. In the Diary of Henry's secretary, there is "ane scarlet beever hatte" presented on new year's day 1443. Even at this early period hats were of various shapes, both in the crowns and the brims; the latter being chiefly broad, sometimes narrowing towards the back, and a little bent up and scooped in front. In Henry's privy purse expenses, during his congress with Francis I. in 1520 or 1521, there is "peid for a hatte and plume for the king, in Boleyn, xv^{s}.;" and in Wolsey's inventory, taken on his resigning the great seal to Sir Thomas More, there are no fewer than five mentioned. The fashion of this article was then much more diversely capricious than even now, as will appear from an extract from Stubbs' *Anatomie of Abuses*, published about 1585: "Sometimes they use them sharpe on the crowne, pearking up like the spire or shaft of a steeple, standing a quarter of a yard above the crowne of theire heads; some more, some lesse, as please the fantasies of their inconstant mindes. Othersome be flat, and broade on the crowne, like the battlements of a house. Another sorte have rounde crownes, sometimes with one kind of bande, sometimes with another; now black, now white, now russed, now redde, now grene, now yellow; now this, now that; never content with one colour or fashion two daies to an end. And as the fashions be rare and strange, so is the stuffe whereof their hattes be made divers also; for some are silk, some of velvet, some of taffetie, some of sarsnet, some of wool, and, which is more curious, some of a certaine kinde of fine haire; these they call bever hattes, of xx. xxx. or xl. shillings price, fetched from beyonde the seas, from whence a great sorte of other vanities doe come besides; and so common a thing it is, that every servyng man, countreiman, and other, even all indifferently, doe weare of these hattes." About the beginning of 1700, the crowns of hats were mostly round, much lower than before, and had very broad brims, resembling what are now occasionally called Quakers' hats, the protrusive encumbrance of which soon suggested the convenience of their being turned up in front; fashion dictated the upbending of another side or flap, and ultimately a third, so that by this progress, in 1704, the regular three-cocked hat became the order of the day, when feathers ceased to be usually worn. Near the middle of the eighteenth century, a round-edged but flat-topped and full-brimmed hat got into very general use, and the flat and other cocked hats now dwindled almost into a mere distinction of real or assumed rank. Twenty-five years after this, a very near approach to that of the present times became fashionable, and, within ten years, altogether superseded the ordinary use of the cumbrous and antique cock.

Plumes, jewels, silk loops, rosettes, badges, gold and silver bands and loops, have at various periods ornamented this article of dress; metal bands and loops being now esteemed proper only to naval and military "men of honour," and the humble liveried attendants on state, rank, and official dignity. The *opera* or soft-folding hat is the only relic at present in general use of the hats worn by our grandfathers, although it is not improbable that the mutations of fashion may re-introduce the elegant Spanish hat as the precursor perhaps of various other styles, as well as the cocked hat, which are not yet entirely discarded.

In the Great Exhibition of 1851 several very novel styles of hat were introduced by British exhibitors. It is remarked in the Jury Report respecting them that "in an article of fashion and of such constant use as hats, it does not appear to be easy to change the habits and tastes of the wearers, or to induce them to adopt a new costume."

Until recent times hats were chiefly produced by the art of felting, an art which some persons suppose to have been practised by the nations of antiquity. It is thought that *lana coacta*, used for soldiers' cloaks and for Lacedemonian hats, was felted wool, but others state that it was only knitted wool. In Roman Catholic countries St Clement is the reputed inventor of felt. This personage is said to have put carded wool into his sandals to protect his feet during a pilgrimage, and that the effect of the moisture, warmth, and friction converted the wool into a felted cloth. The hatters' annual festival is on the 23d November, St Clement's Day.

HAT-MAKING embraces two distinct kinds of manufacture, viz., of *felted*, and *covered* hats; the covering of the latter being generally plush. *Felted* hats comprehend two classes, differing chiefly in the materials used in making, the processes being nearly identical. The lower class is marked by inferior ingredients, unmixed with beaver, and embraces *wool*, *plated*, and *short nap* hats. *Wool* hats are made entirely of coarse native wool and hair stiffened with glue. Before the emancipation act these hats were largely exported for negroes' wear; but the manufacture is now almost extinct. *Plates* have a *nap* or pile rather finer than their body, and are sometimes *waterproof* stiffened. *Short naps* are distinguished from *plates* by additional kinds of wool, viz., hare's back, seal, neuter or nutria, musquash (Muscovy cat), and are all waterproof stiffened.

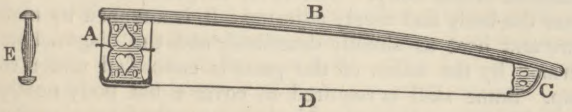
The second class may be said to comprehend two orders, called *stuff* and *beaver* hats. The first includes mottled and stuff bodies. The latter term is not used generally, as all *stuffs* are understood to be of this sort when *mottled* is not expressed. *Mottled bodies* are made chiefly of fine Spanish wool, and inferior rabbit down or coney wool. *Stuff bodies* consist of the best hare, Saxony, and red wools, mixed with Cashmere hair and silks. *Stuff* hats are *napped*, that is, covered with pile of mixed seal, neuter, hare-back, inferior beaver, and musquash. *Beaver* hats are, or ought to be, napped with beaver only; the lower priced qualities with *brown wooms* taken from the back; the more valuable kinds with *cheek* and *white wooms*, such being the finest parts of the fur found on the belly and cheeks of the beaver.

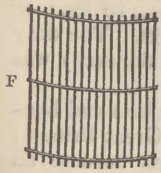
The manufacture of a beaver hat involves a number of curious and interesting processes, the most important of which is *felting*, or the art of combining animal fibres in such a way as to form, without weaving, a thick compact cloth. The felting property of animal fibres depends on their peculiar structure, which, as revealed by the microscope, appears to be notched or jagged at the edges with teeth directed from the root towards the extremity. Wool in the yolk, or with the natural grease adhering to it, does not readily felt, the jagged portions being smoothed over or filled up with the oil; but when the fibres of clean wool or hair are made to undergo a gentle friction under the influence of moisture and heat they readily felt together.

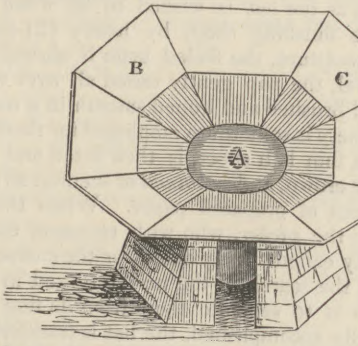
Several of the furs mentioned above (see also Fur Trade) are used for hats. The beaver has been so assiduously hunted during many years that it is now becoming a rarity, and the fur of other animals is substituted for it. The coypu furnishes nutria skin; the musquash or musk-rat, the hare, and the rabbit, yield fur for the nap of the hat, while the body is made of lamb's wool, or of the woolly hair of the llama or vicuna.

A beaver hat, properly so called, has a body or foundation of rabbits' fur, with a beaver nap, although the beaver, for the reason above stated, is often mixed with a more common fur. Such a hat has a pleasant softness and plasticity, and readily moulds itself to the shape of the head, presenting a marked contrast to the hard, horny, silk hat, which has nearly superseded it. Still, however, there must always be certain persons who, not objecting to the price, will continue to keep alive this the most interesting branch of the hat manufacture, and it is our duty to describe its processes.

The beaver hat, with the body of rabbits' fur and a beaver nap, may be regarded as the highest achievement of the hatter. A cheaper kind has the body of lambs' wool, and the nap of some fur cheaper than beaver. Such is the *plate* hat, so called from an analogy with plated metal goods, the exposed surface being of the more valuable material upon an inferior base or foundation. A notice of the mode of preparing a plate hat will sufficiently show the nature of the processes concerned in the manufacture of a beaver hat. In preparing this fur plate, the hatter weighs out an ounce of beaver down, a quarter of an ounce of musquash, and a quarter of an ounce of cotton wool, which last ingredient serves the temporary purpose of preventing the surfaces of the beaver from felting together instead of adhering to the body. These three substances are spread out and combined by the operation of bowing. The bow or stang, ABC, is about seven feet long, and is usually of ash: A is called the *breech*, and C the *cock*. The stang is suspended by a string over the bench where the operation is performed. It stretches a single cord of cat-gut, D, which the workman vibrates by means of a wooden pin, E, furnished with a half knob at each end. Holding the bow in his left hand, and the pin in his right, he causes the vibrating string to come in contact with the heap of tangled fur, which does not cover a space greater than that of the hand. At each vibration some of the filaments start up to the height of a few inches, and fall away from the mass, a little to the right of the bow, their excursions being restrained by a concave frame of wicker-work F, called the *basket*. In the course of a few minutes the fibres are completely separated, and spread over a considerable space. They are then divided as nearly as possible, and one half laid aside, whilst the other is again bowed. In this second operation, partly by the bowing, but chiefly by the *gathering*, or patting use of the basket, the stuff is loosely matted into a conical figure, about fifty by thirty-six inches, called a *bat*. In this formation care is taken to work about two-thirds of the wools down towards what is intended for the brim, which being effected greater density is induced by gentle pressure with the basket. It is then covered with a wettish linen cloth, upon which is laid the *hardening skin*, a piece of dry half-tanned horse hide. On this the workman presses or *bakes* for seven or eight minutes, until the stuff adheres closely to the damp cloth, in which it is then doubled up, freely pressed with the hand, and laid aside. By this process, called *basoning* (from a metal plate or bason, used for like purposes in making *wool* hats), the bat has become compactly felted and thinned toward the sides and point. The other half of the flocked stuff is next subjected to precisely the same processes; after which, a cone-shaped slip of stiff paper is laid on its surface, and the sides of the bat are folded over its edges to its form and size. It is then laid paper-side downward upon the first bat, which is now replaced on the hurdle, and its edges are transversely doubled over the introverted side-lays of the second bat, thus giving equal thickness to the whole *body*. In this condition it is re-introduced between folds of damp linen cloth, and again hardened, so as to unite both halves, the knitting together of which is quickly effected. The paper is now withdrawn; and the body, being folded into three plies, is removed to the plank or battery room.







The battery consists of an open iron boiler or kettle A, with shelves B, C, partly of mahogany and partly of lead, sloping down to it. The liquor in the battery is of a scalding heat, and consists of pure soft water, about half a gill of oil of vitriol as an astringent, and a full handful of oatmeal to correct its corrosive tendencies. Herein the body is imbued, and then withdrawn to the plank to partly cool and drain, when it is unfolded, rolled gently with a pin tapering towards the ends, turned, and worked in every direction, to toughen, shrink, and at the same time prevent adhesion of its sides. *Stopping* or thickening the thin spots which now appear on looking through the body, is carefully performed by dabbing on additional stuff in successive supplies from the hot liquor, with a brush frequently dipped into the kettle, until the body be shrunk sufficiently (about one half), and thoroughly equalized. When quite dried, *stiffening* is performed with a brush dipped into a glutinous pulpy composition, and rubbed into the body; the surface intended for the inside having much more laid on it than the outer, while the brim is made to absorb many times the quantity applied to any other part. This viscous matter contains *proofing*, or those ingredients which render the hat waterproof.

On being again dried, the body is ready to be *covered*, and is once more taken to the battery. The first cover of beaver or napping, which has been previously *bowed*, is strewed equally over the body, and patted with the brush charged with the hot liquor, until incorporated; the *cut* ends only inserting themselves. The body is now put into a coarse hair-cloth dipped and rolled in the hot liquor, until the beaver is quite worked in. This is called *rolling off*, or *ruffing*. A stripe for the brim, round the edge of the inside, is treated in like manner, and is thus prepared for the second cover, which is applied and worked in similarly; the rolling, &c., being continued until the whole has become incorporated, and a clean, regular, close, and well-felted *hood* is the result. The dry hood, after having the nap beat up and freed, is clipped to the desired length by means of shears, or by the clipping machine, which is preferable on account of its performing the work with greater speed and regularity. When the nap is thus disposed of, the hood is soaked in the battery kettle, then *drawn down* on a block to the size and shape wanted, and firmly tied at the bottom with a cord, around which the brim is left in a frilled condition.

Dyeing is the next step. A *suit*, or six dozen, all mounted on the crown-blocks and hung round a circular frame, are put into the dye kettle, and allowed to remain three-quarters of an hour in the liquor, which is kept as near as possible one degree below the boiling point. These being taken out and set in the yard to cool, another suit is introduced for a like period; and the various suits are so treated at least twelve times in successive order. Each of the first four steepings of every suit is accompanied by about 7 lbs. of copperas, and 2 lbs. of verdigris. The body is then washed and brushed out in changes of hot water, until it ceases to give off colour. When thus thoroughly cleansed, it is steamed on a block, shaped as the hat is wished to be when complete; and in the finishing shop, by heavy (21-pound) heated irons and moisture, the frilled brim is shrunk until rendered quite level, the nap gently raised all over with a fine wire card, and brushed and ironed smooth in a uniform direction. Machinery is sometimes employed for these purposes. The tip, a thin lath sheet, is then fitted and stuck to the inside of the crown, and *robbined* or secured all round the edges by stripes of prepared paper. When thus *got down*, it is sent to the *picker*, who with tweezers extracts the *kemps*, vulgarly called "grey hairs," or the coarse hairs that have escaped the search of the machine used in blowing the beaver, so as to separate them from its fine parts. This being carefully accomplished, the hat is transferred to the finisher, who, with a plush cushion or *velure*, a brush, and hot iron, imparts to it a bright sleeky lustre. The *shaper* then rounds the brim with a knife and notched segment to the breadth wanted; and shapes it in varied styles by means of a hot iron and damp, with about a foot length of rope, over which the *curl* is laid. The *trimming* is next done, when the *tipper off* corrects the twists, smooths the ruffled nap caused by trimming, and *papers* it up with tissue and cartridge, which completes it for the retailer.

Dye-stuffs for a gross of beaver hats.—About 180 gallons of pure soft water, 1½ cwt. of best Campeachy logwood, 8 lbs. of oxide of copper, and 30 lbs. of copperas. It is to be observed, however, that some put the chips, others only the juice, of the logwood into the dye-kettle. Galls are now disused. *Stiffening stuffs.*—Makers differ in the proportions, but the ingredients are shell-lac, rosin, mastic, sandarach, and elemi, all churned until dissolved. A quantity of this is then melted over steam, sieved, put in hot, and well mixed. *Cleaning stuffs.*—These are now seldom considered necessary. Half a pound of borax, diluted in five gallons of water, into which the stiffened nap is dipped, and then well brushed.

The trade is now almost exclusively occupied in the manufacture of silk hats, which forms a distinct branch; and scarcely in any respect in its earlier stages, resembles the beaver hat manufacture. The hat body may consist of wool, stuff, willow, straw, cambric, woollen cloth, or calico: linen or calico are very common. For the latter material the body is moulded on an oval block generally made up of five segments; a piece of calico is first folded round the block and the edges secured with a solution of shell-lac or some adhesive compound. The surface of the calico is next coated with the shell-lac solution, and another layer of calico is wound round and coated as before, the edges of the top being turned down to form a portion of the crown; other layers of calico are similarly put on, until the desired thickness is attained. The crown consists of disks of calico, and the brim is formed by attaching an oval piece of calico to a piece of twilt; the centre of the oval is now cut away to the size of the hat, and the brim thus formed is secured to the hat body by cementing one of its loose edges to the inside, and the other to the outside of the body, the brim being further secured by a strap of calico, called a *band-robbin*, saturated with cement, and passed round near the juncture. The tip being fitted and robbined, the whole of the exterior is covered with cement, and when quite dry, the proper width of the brim is adjusted by means of a gauge and a knife, the gauge consisting of the segment of an oval attached to a straight rod at right angles with the longer axis, and furnished with notches for the reception of the back of the knife at the proper distance. The body is now ready for covering with silk plush, which is woven like velvet and has a nap or shag on one side; it is partly supplied to this country from Lyons, whence this kind of hat is called a *French hat*, but it is also manufactured at Banbury, Coventry, and in Spitalfields. It is cut into threes, namely, a circular piece for the crown of the hat, a rhomboidal piece for the side, and a long slip for the brim. The latter is cut of greater width than is sufficient to cover both sides of the brim, and the two ends are sewn together; the crown and the side piece are also sewn together, the sloping opening at the side being left unsewn. The hat body being smoothed with sand-paper, the strip for the brim is put on, wetted with a sponge, and the adhesion completed by means of a hot iron, the moisture and heat temporarily dissolving a portion of the shell-lac. In fitting on the brim-strip the workman is furnished with a brass wire attached to a rope stirrup; this wire serves him as a third hand, for he can gather up under it, and hold fast the various puckers that are formed, while both hands are at liberty to make the required adjustment, and when once he is satisfied, the wet sponge and the hot iron fix his work. The superfluous portions above the wire are either cut off, or, for the under part of the brim, are turned inside the hat and attached to the body. The cover of plush is next drawn over the body and nicely adjusted; it is attached by moisture and heat as already described, and the diagonal line formed by the union of the parts is concealed under the nap. Some skill is required to cover a hat body neatly; but this being done, the plush is smoothed by a carding comb, a box-wood dummy, and a velvet cushion. After the hat has been trimmed and lined by women, the brim receives its shape, and the body itself may also be considerably modified by the aid of a stove-heat. Loose or imperfect filaments are now removed by means of a steel picker, the hat is once more polished up, and being packed in paper is ready for the market.

The exports in 1854 of hats manufactured in the United Kingdom amounted to 138,060 dozen; the declared real value of these being L.252,102. In the same year the quantity imported of silk plush for hats was 144,116 lbs.; of which the computed real value was L.86,469. The duty on imported hats (at one time as high as 10s. 6d. each), was reduced in 1853 to 1s.

HATS, *Straw*. The manufacture of straw hats and bonnets has only existed for about a century in Great Britain; yet it has attained great perfection, and has become an important branch of industry. In no other part of the world, except North America, is the custom of wearing bonnets so universal as among the women of this country. A constant demand is thus created for the article; and to this may partly be attributed the progress of the home manufacture. Large importations were formerly made of the beautiful straw hats of Leghorn and Tuscany, which were celebrated two centuries ago; but this commerce, being disturbed by political troubles, gradually declined, while our own manufacture from indigenous grasses received encouragement. Still the fine rich colour of the Tuscan straw, its smoothness, and beauty, caused it to be much valued, and imported hither to be worked up by our own people after the Italian method. By this method a broad flat plait is produced in the following manner:—A certain number of straws, frequently thirteen, equal in colour and fineness, are tied together at one end. They are then divided into two bundles, six turned to the left and seven to the right. The seventh, or outer straw, on the right, is then turned down, and brought under two straws, over two, and under two. There are now seven straws to the left, where the outer straw is again taken and turned down under two, over two, and under two. Thus, backwards and forwards, the plaiting proceeds, until a straw is used up. Another straw is then put in under the short end in the middle of the plait, and is fastened by the crossing of the other straws over and under it. This kind of plait is formed in pieces of great length, which are adjusted, according to the Italian method, in large coils, so as to form *flats*, as they are called, the edges being cleverly knitted together by a thread, which is run strait along in the interior, and entirely concealed. The demand for this kind of plait is now very limited, the fashion having been superseded by fancy straw-plaits like those of Switzerland, which are now produced in such great variety in this country. The chief seats of manufacture of British straw-plait are the counties of Bedford, Hertford, and Buckingham, and in these and some other counties a population of about 70,000 persons is said to be employed in this trade, producing a yearly return which has been reckoned at from L.800,000 to L.900,000. In the end of the last century, *straw-plaiting* was successfully introduced into the Orkneys and other parts of the N. of Scotland. In the case of British-grown straw, the process is as follows:—The best and whitest straws are selected, cut into equal lengths, bleached by exposure to fumes of burning sulphur, and split lengthways into several segments. The splitting is performed by means of a wire, having four, six, or eight sharp, cutting edges, which is passed up the middle of the straw. The slips of straw are then softened in water, and are in a convenient state for plaiting. As the plait is formed it is passed between wooden rollers to make it flat and hard. The hat or bonnet is formed by winding this plait on a wooden shape in a spiral direction, leaving a little overlap, which is sewed to the part beneath, and then pressed with a hot iron. At the present time, however, the taste for fancy bonnets has lessened the demand for simple straw bonnets of this kind. Various new materials—Brazilian grass, whalebone, shavings, &c.—are introduced into the manufacture; and mixtures of straws, British and foreign, are invented to gratify the love of novelty. This manufacture is healthy and domestic, and is of great value as an employment for women and children.

The description of straw used, which is cultivated solely for the purposes of the manufacture, and not for the grain, is the *Triticum turgidum*, a variety of bearded wheat, which seems to differ in no respect from the spring wheat grown in the vale of Evesham and other parts of England. (*Trans. of Soc. of Arts.*) After undergoing a certain preparatory process, the upper parts of the stems (being first sorted as to colour and thickness) are formed into a plait of generally thirteen straws, which is afterwards knitted together at the edges into a circular shape called a "flat," or hat. The fineness of the flats is determined by the number of rows of plait which compose them, counting from the bottom of the crown to the edge of the brim, and their relative fineness ranges from about No. 20 to 60, being the rows contained in the breadth of the brim, which is generally eight inches. They are afterwards assorted into first, second, and third qualities, which are determined by the *colour* and *texture*; the most faultless being denominated the first, whilst the most defective is described as the third quality. These qualities are much influenced by the season of the year in which the straw is plaited. Spring is the most favourable, not only for plaiting, but for bleaching and finishing. The dust and perspiration in summer, and the benumbed fingers of the workwomen in winter, when they are compelled to keep within their smoky huts, plaiting the cold and wet straw, are equally injurious to the colour of the hats, which no bleaching can improve. The flats are afterwards made up in cases of ten or twenty dozen, assorted in progressive numbers or qualities, and the price of the middle or average number governs the whole. The *Brozzi* make bears the highest repute, and the *Signa* is considered secondary; which names are given to the flats, from the districts where they are plaited. Florence is the principal market, and the demand is chiefly from England, France, Germany, and America; but the kinds mostly required are the lower numbers; the very finest hats, particularly of late, being considered too expensive by the buyers. (C. T.)

HATCH, in *Mining*, an opening into a mine, or in search of one. The term *hatches* is also applied to the earthen dams used in Cornwall to prevent the water that issues from the stream-works and tin-washes from running into the fresh rivers.

HATCH, or *Hatches*, properly the grate or frame of cross-bars laid over a ship's deck, now denominated "hatch-bars." The lid or cover of a hatchway is also called hatches. Hatch is sometimes applied to the opening in the ship's deck; but this is properly called the hatchway.

HATCHEL, a tool (of various degrees of fineness) used for dressing and combing flax and hemp. It resembles a card, consisting of sharp-pointed iron pins or teeth set regularly in a board.

HATCHMENT, a corruption of *atchievement*, in *Heraldry*, the coat-of-arms of a person dead, usually placed on the front of a house, by which the rank of the deceased may be known; the whole being distinguished in such a manner as to enable the beholder to know whether he was a bachelor, a married man, or a widower. There are similar distinctions for women.

HATCHWAY, a square or oblong opening in the deck of a ship, affording a passage into the hold, or from one deck to another. Hatchway is also applied to the passage through a falling door in the top of a house. In ships, the main-hatchway is placed before the mainmast, and is the largest in the ship; the fore-hatchway is a little abaft the foremast, or at the break of the forecastle; and the after-hatchway between the mainmast and the mizzen.

HATFIELD, or BISHOP'S HATFIELD, a market-town of England, county of Hertford, on the side of a hill, 19 miles N.N.W. of London. The parish church is a handsome edifice, with an embattled tower and spire; but the most remarkable edifice here is Hatfield House, the magnificent seat of the Marquis of Salisbury, erected in the beginning of the seventeenth century. The old house was the residence of Prince Edward, afterwards Edward VI., immediately before his accession. Princess (afterwards Queen) Elizabeth lived here, under the charge of Sir T. Pope, during the latter part of the reign of her sister Mary. Hatfield was, soon after the accession of James I., made over, in exchange for Theobalds, to Sir R. Cecil, afterwards Earl of Salisbury, in whose family it has since remained. The gateway and end of the old palace are still standing. The present building was erected by Sir R. Cecil. In November 1835 the left wing was destroyed by fire, on which occasion the Dowager Marchioness of Salisbury perished in the flames. The grounds are beautifully laid out. Market-day, Wednesday. Pop. of parish (1851) 3862.

HATHERLEIGH, a market-town of England, county of Devon, on a branch of the Torridge, 28 miles W.N.W. of Exeter. It is mean and irregularly built, and the inhabitants are chiefly engaged in agriculture. Some are still engaged in the woollen manufacture, though this branch of industry has of late years declined. Market-day, Friday. Pop. of parish (1851) 1710.

HATRAS, a town of Hindustan, in the district of Allyghur, under the jurisdiction of the lieutenant-governor of the N.W. provinces. At the commencement of the Mahratta war, in 1817, the hostile demeanour of the petty chief of this place was fraught with danger, and it became necessary to dislodge him. Dya Ram, who held the place at that time was accordingly summoned to surrender the fort. Trusting in the defences, which had been strengthened in imitation of those of the neighbouring fort of Allyghur, by preparing a covered way and raising a glacis, the occupant refused compliance; whereupon, on the 23d February 1817 the town was breached and evacuated, and on the 1st March fire was opened on the fort from forty-five mortars and three breaching-batteries of heavy guns. At the close of the same day a magazine in the fort exploded, and caused such destruction that Dya Ram, terror-struck, abandoned the place in the course of the night. The population of this town, which is the chief mart for the cotton produced in the province, is returned at 20,504. N. Lat. 27. 36., E. Long. 78. 9.

HATTEMISTS, a modern Dutch sect, who adopted the principles of Pontian Van Hattem. They believed in uncontrollable necessity, denied human depravity and the distinction between good and evil, as well as that Christ made expiation for sin. They made religion to consist in suffering cheerfully whatever happens by the will of God, who punished men not for, but by their sins. Their founder seems to have broached his system principally under the influence of Spinoza.

HAUBERK, a coat of chain or of ringed mail, with wide sleeves reaching a little below the elbow, and having a hood. In France this species of armour was a mark of dignity, and appropriated to knights, esquires being restricted to a simple coat of mail, without the hood and the hose of mail.

HAUKSBEE, or HAWKSBEE, FRANCIS, an ingenious natural philosopher of the eighteenth century. His contributions to science are noticed particularly in the historical part of the article ELECTRICITY, and in the Fifth Dissertation prefixed to this work.

HAUNCH, the hip, or that part of the body between the ribs and thigh.

HAURIANT, in *Heraldry*, a term applied to fishes when placed upright, as if sucking in the air.

HAUTBOY (Ital. *Oboe*), a wind instrument of the reed kind; of a pleasing and rather melancholy *timbre*. Anciently there were hautboys of different sizes. For the compass and use of the modern hautboy, see MUSIC. In some organs there is a stop called the hautboy-stop, consisting of reed-pipes.

HAUY, RÉNÉ JUST, an eminent French mineralogist, was born at St Just, in the department of Oise, Feb. 28th, 1743. His parents were in an humble rank of life, and were only enabled by the kindness of friends to educate their son. He was sent to Paris to the College of Navarre, and afterwards to that of Lemoine, where he finished his course amid incredible privations and difficulties. He escaped from these, when, in 1764, he was himself appointed one of the teachers in the first of the above-named colleges. He began to devote his leisure hours to the study of botany, but an accident directed his attention to another field in natural history. Happening to let fall a beautiful specimen of calcareous spar belonging to a friend, he discovered, by examining the fragments, the geometrical law of crystallization. (See CRYSTALLIZATION.) Daubenton and Laplace immediately recognized the scientific value of the discovery, which, when communicated to the Royal Academy, secured for its author a place in that society. When the Revolution broke out, Haüy was thrown into prison, and his life was even in danger, when he was saved by the intercession of Geoffroy St Hilaire. Under Napoleon, he became professor of mineralogy at the Museum of Natural History. He also obtained other scientific preferment, of which he was deprived by the feeble and fanatical government of the Restoration, though his royalism had been a serious bar to his promotion under the Empire. His latter days were consequently clouded by the poverty which had threatened to blight his early career. But the courage and high moral qualities which had helped him forward in his youth did not desert him in his old age; and, as France is a country where poverty does not necessarily entail neglect or contempt, Haüy lived cheerful and respected till his death, June 3, 1823. The following are his principal works:—

Essai d'une Théorie sur la Structure des Cristaux, 1784, in 8vo; *Exposition raisonnée de la Théorie de l'Electricité et du Magnétisme, d'après les Principes d'Æpinus*, 1787, in 8vo; *De la Structure considérée comme Caractère Distinctif des Minéraux*, 1793, in 8vo; *Exposition abrégée de la Théorie de la Structure des Cristaux*, 1793, in 8vo; *Extrait d'un Traité Elémentaire de Minéralogie*, 1797, in 8vo; *Traité de Minéralogie*, 1802, 4 vols. in 8vo, et planches in 4to; *Traité Elémentaire de Physique*, 1803, in 12mo, deuxième edition, in 1806, 2 vols. 8vo; *Tableau Comparatif des Résultats de la Cristallographie, et de l'Analyse Chimique relativement à la Classification des Minéraux; Traité des Pierres Précieuses*, 1817, in 8vo; *Traité de Cristalographie*, 1822, 2 vols. with engravings. M. Haüy also contributed papers to various scientific journals, particularly the *Journal d'Histoire Naturelle*, *Annales de Chimie*, the *Journal de Physique*, the *Magasin Encyclopédique*, the *Annales du Muséum d'Histoire Naturelle*, and the *Journal des Mines*. He also communicated several memoirs to various other scientific journals.

HAVANA (HABANA), the capital of Cuba, and the most important commercial city in the West Indies, is situated on the northern side of the island, in N. Lat. 23. 8. 15., W. Long. 82. 22. 5. It stands on the W. side of the entrance of a magnificent land-locked harbour, capable of accommodating with safety 1000 vessels. The entrance, between the Moro and Punta castles, which protect it, is 1500 yards long, by, and at its narrowest point, 350 wide; and has a depth of 8 fathoms water. A continuous series of batteries run along both shores; and the town is defended by walls, a strong citadel, and fortifications on the neighbouring heights. The streets of the city are narrow and dirty, but straight, and cross each other at right angles. In the matter of cleanliness, however, a great improvement has lately taken place. The houses are constructed of stout masonry, generally of one storey, and many of the private residences are costly and magnificent structures. The suburbs are considerably larger than the town itself, and are better laid out; that of Regla is on the opposite side of the harbour. Among its most conspicuous buildings are—the cathedral (in which the remains of Columbus now lie), the government palace, admiralty, post-office, royal tobacco factory, and the *casa de beneficiencia*. There are numerous churches, convents, and schools in the city, a university, ecclesiastical seminary, theatre, and other places of public amusement. Havaña is connected by railway with Batabana, Matanzas, &c. Pop. (1850) 150,561. See CUBA.

HAVANT, a small market-town in Hampshire, at the head of Langston harbour, 21 miles E. by S. from Southampton. The principal building is the church, a cruciform edifice, surmounted by a tower; some portions of it are very old. There is also a district church, dedicated to St John; a Baptist, and an Independent meeting-house. Havant possesses no trade, and no manufacture beyond that of a little parchment. Market-day, Saturday. Pop. of parish (1851), 2416.

HAVEL, a navigable affluent of the Elbe, rising in several lakes in the S.E. part of Mecklenburg-Schwerin, flows through several lakes in its course, and joins the Elbe below Havelberg. The chief towns on its banks are, Oranienburg, Spandau, Potsdam, Brandenburg, Plane, Rathenow, and

Havelberg. Its chief affluents are—on the left, the Spree, Nuthe, Plane, and Stremme; on the right, the Rhin and the Dosse. It is about 180 miles in length, is navigable for boats through its entire extent, and for ships from Fürstenberg.

HAVERCAMP, Sigibert, a distinguished Dutch scholar, was born at Utrecht in 1683. He succeeded Gronovius as professor of Greek at Leyden, and held at the same time the chairs of rhetoric and history. He was undoubtedly a learned man and a laborious scholar, but his works, which were written for the most part hastily and carelessly, are now forgotten. The most important of them are his—

Editions of the *Apologetica* of Tertullian, 1718, in 8vo; of Lucretius, 1725, in 2 vols. 4to; of the History of Josephus, 1726, in 2 vols. folio; of Eutropius, 1729, in 8vo; of Orosius, 1738, in 4to; of Sallust, 1742, in 2 vols. 4to; and, lastly, of Censorinus, 1743, in 8vo; *Dissertationes de Alexandri Magni numismate quo quatuor summa orbis terrarum imperia continentur, et de nummis contorniatis*, Leyden, 1722, in 4to; *Thesaurus Morellianus*, Amsterdam, in 2 vols. folio; *Universal History explained by Medals*, in Dutch, Leyden, 1736, in 5 vols. folio, incomplete; *Sylloge Scriptorum qui de Linguæ Græcæ vera et recta pronunciatione Commentaria reliquerunt*, Leyden, 1736–1740, in 2 vols. 8vo; *Introductio in historiam patriæ a primis Hollandiæ comitibus usque ad pacem Ultraject. et Radstad* (1714), Leyden, 1739, in 8vo; *Introductio in Antiquitates Romanas*, ibid. 1740, in 8vo; *Museum Wildianum in duas partes divisum*, Amsterdam, 1740, in 8vo; *Museum Vilebrochianum*, ibid. 1741, in 8vo; *Bronze Medals*, large and small, in the Cabinet of Queen Christina, Hague, 1742, in folio.

HAVERFORDWEST, in Welsh Hwlffordd, a market-town, seaport, and parliamentary and municipal borough of Wales, in Pembrokeshire, and the capital of that county. It stands on a declivity descending to the banks of the West Cleddan. Some of the streets are wide and handsome; but in the older parts of the town they are narrow, and generally very steep. Viewed from a little distance, the aspect of the town is very picturesque. The majority of the shops and houses have an air of wealth and comfort, arising from the fact that many persons of independent means have been attracted to the town by its character for cheapness. The principal public buildings are the Guildhall market-house; the three parish churches; the various dissenting chapels; a Free school; an almshouse; and a large union poorhouse. A literary and scientific institution was established in 1847; and one newspaper, the *Pembrokeshire Herald*, is published weekly.

Haverfordwest was at one time strongly fortified, but all traces of its walls and towers have long since disappeared. On a rock overhanging the river was a strong castle, built in the reign of Stephen by Gilbert de Clare, first Earl of Pembroke. In the insurrection of Owen Glyndwr, it was successfully defended against the French troops in the Welsh service. In the civil war of the 17th century it was held by the royalists. The only remaining vestige of the castle is the keep, which has been largely added to, and converted into the county gaol. In the neighbourhood of the town are the ruins of a priory, dating from the 12th century, and dedicated to St Mary and St Thomas.

On the N. side of the river is the suburb of Prendergast, where are the remains of a very ancient mansion, formerly occupied by a family of that name. The river itself is navigable at spring tides as far as the quay, where there is a custom-house, subordinate to that of Milford. The town exports in some quantity coal, oats, butter, and cattle. The only manufactory of importance is a large paper-mill. The market held on Tuesday and Saturday is one of the largest in Wales; the supply of fish in particular is very abundant. The assizes and quarter-sessions for Pembrokeshire are held in Haverfordwest, which, with the contributory boroughs of Fishguard and Harberth, returns one member to parliament. Registered electors (1851) 686; pop. 6580.

HAVERHILL, a small market-town of England, county of Suffolk, 25 miles N. of Chelmsford, and 59 miles from London. It was formerly a place of greater importance than at present, and had considerable manufactures of checks and fustians, which have now dwindled away. The weaving of silk, cotton, &c., is still to some extent carried on. The parish church is a large and ancient edifice. Pop. of parish (1851) 2535.

Haverhill, a flourishing village in the United States of North America, Massachusetts, on the N. bank of the Merrimac River, at the head of its navigation, and about 15 miles from the ocean. It stands on the Boston and Maine railways; and has manufactures of boots and shoes, woollen goods, bricks, silver-ware, hats, &c. Pop. (1853) about 3500.

HAVRE, LE, or Havre de Grace, the principal commercial seaport on the west coast of France, and a sub-prefecture and chief town of the department of Seine-Inférieure. It stands on the N. bank of the estuary of the Seine, in N. Lat. 49. 29. 14., and W. Long. 0. 6. 38.; by railway 143 miles from Paris, 127 from Poissy, 108 from Mantes, 55½ from Rouen, and 32 from Yvetot. It is the port of the Seine and of Paris, and one of the most thriving maritime towns of France. It is quite modern in its construction, chiefly built on a low alluvial tract of ground, and divided into two parts by its outer port and basins. It has no fine buildings or historical monuments; its streets run chiefly in straight lines and at right angles with one another; and they are grouped round the basins or docks which communicate by lock-gates, and are placed so as to form a triangle entered from the outer port.

Havre is a fortified town of the third rank; a maritime prefecture, with a tribunal of the first instance and of commerce; an exchange and a chamber of commerce; a hydrographic school of the first class; a maritime arsenal, &c. The mouth of the harbour, formed in the flat alluvium of the Seine, is kept open by the aid of a reservoir of water, regulated by sluices. During only four hours each tide can vessels enter the port, which is left dry at low water. The three old docks are capable of containing from 200 to 300 vessels; the third, the Bassin de Vauban, the largest of all, situated outside the walls, and finished in 1842, is a magnificent work with a fine masting machine, and warehouses of the best construction. At the extremity of the reservoir has been constructed a fifth dock for steamers.

Napoleon said that "Paris, Rouen, and Havre, formed only one city, of which the Seine was the highway." This briefly accounts for the prosperity of Havre. It is the place of import of all foreign articles required for the supply of the French capital, as well as of cotton for the manufacturers of Rouen, Lille, St Quentin, and Alsace, which cities again export through Havre their manufactured goods. Like Liverpool, it is the point of communication between the continent of Europe and America; and a great trade has been here carried on with the United States since the declaration of their independence. Though Havre is much inferior in size to Marseilles, Bordeaux, or Nantes, the other great mercantile ports of France, yet it yields to none of them in activity. Its imports, though only half the weight of those of Marseilles, nearly equal them in value. The chief imports from America by Havre are coffee, indigo, hides, peltry; but above all, cotton for the Rouen and Mulhausen factories. From Spain are imported wine, oil, barilla, and timber; from Sweden and Norway, deals, planks, masts, pitch, and tar.

The manufactures of Havre are not numerous or extensive. They consist mostly of chemicals, starch, oil, tobacco, tar, cordage, sailcloth, cables, earthenware, furniture, and lace. The Havre station of the Paris, Rouen, and Havre railway covers an area of 36 acres. Pop. (1851) 26,410.

In 1509 Louis VII. founded Havre; and Francis I. took it under his special protection, bestowing upon it the name of Franciscopolis; but a chapel dedicated to Notre-Dame de Grace ultimately conferred on it its present name. The French East India Company and the Companies of Senegal and Guinea made it their entrepôt and the chief seat of their commercial operations. In 1759 (during the Seven Years' War) preparations were made here for an invasion of England, which led to the bombardment of the place by Admiral Rodney. In 1794 and 1795 it was again bombarded by the British.

In 1485 Henry of Richmond embarked at this place for Milford Haven and Bosworth Field with 4000 men, furnished by Charles VIII., to aid his enterprise. The town was delivered over to the keeping of Queen Elizabeth by the Prince de Condé, leader of the Huguenots, in 1562, and the command of it was entrusted to Ambrose Dudley, Earl of Warwick; but the English were expelled within a year, after a most obstinate siege, the progress of which was pressed forward by Charles IX. and his mother, Catherine de Medici, in person.

Havre is the birthplace of Bernardin de St Pierre, author of *Paul and Virginia;* and of Mademoiselle Scudery, and of Casimir Delavigne.

HAW, in farriery, an excrescence resembling a gristle, growing under the nether eyelid and eye of a horse, which, if not timely removed, destroys it.

HAW, a small parcel of land, as a *Hemphaw*, or *Beanhaw*, lying near the dwelling-house, and enclosed for these uses. But Sir Edward Coke, in an ancient plea concerning Feversham in Kent, says *hawes* are houses.

HAWAII. See POLYNESIA.

HAWARDEN, a small market-town of North Wales, Flintshire, 12 miles W.N.W. of Chester. It consists of little more than one street, about half a mile in length. The collieries, potteries, and iron-works in the vicinity afford employment to the inhabitants. Hawarden Castle is a handsome modern edifice, with an extensive park, in which are the ruins of the ancient castle, supposed to have been built by the Britons. Pop. of parish, which is extensive (1851), 6203.

HAWASH, a river of Abyssinia. See ABYSSINIA.

HAWES, STEPHEN, the author of the *Pastime of Pleasure*, flourished in the reign of Henry VII. Little is known of his personal history, except that he was a native of Suffolk, and that he styled himself "gentleman and grome of the chamber to the famous prynce and seconde Solomon, Kynge Henrye the Seventh." He is known to have been a great favourite with the king, who took much pleasure in his recitations from the old English poets. A common admiration of the literature of France, in which both were proficients, cemented their feelings of mutual esteem. The dates of Hawes' birth and death are alike unknown. The *Pastime of Pleasure*, for which he is chiefly remembered, is a long and somewhat tedious allegory; exhibiting, however, more invention than any similar work of that day. The poem describes the life and adventures of the Prince Graunde Amour, who is enamoured of La Bel Pucell, and who, to make himself worthy of her, studies, in the Tower of Doctrine under the Ladies Grammar, Logic, Rhetoric, Arithmetic, and Music. He then visits the Tower of Geometry, and finally that of Chivalry; and, after proving his valour by various exploits, he at length gains the hand of La Bel Pucell, with whom he spends the rest of his life. The details of the allegory are wrought out with very considerable skill, and the poem is useful as showing the advancement of the language towards that perfection which it reached under the master-minds of the Elizabethan era.

HAWICK, a town in the county of Roxburgh, Scotland, 10 miles S.W. from Jedburgh, the county town, and 53 miles S.S.E. from Edinburgh by the Hawick branch of the North British railway. It stands on the S. bank of the Teviot, and is divided into nearly equal parts by a wild and irregular stream, the Slitrig, which has been known to rise more than 20 feet above its ordinary level, sweeping away houses, and leaving the foundation rock without a vestige of building-material or soil. Hawick is of undoubted antiquity, being mentioned in the *Chronicles of Melrose* as early as 1214; and the name itself is of Saxon derivation. But the strongest testimony to the early settlement of the spot is afforded by an artificial mound at the upper end of the town, called the Moat, having 312 feet circumference at the base, an elevation of 30 feet, and a nearly level top of 117 feet in circumference. Its origin is entirely lost; but Mr Jeffrey, whose acquaintance with the historical memorials of the Scottish border is perhaps unparalleled, throws out the conjectures, in his *History and Antiquities of Roxburghshire*, that "the children of the Gadeni may have used it as a burying-place for their dead, and their descendants afterwards have converted it into a moathill; or it may have been used from a very early period as a place for enacting as well as administering laws. . . There can be no doubt (he adds) that in later times the flat top of the Hawick Moat was used by the judge of the day for hearing the rude suitors of the district." Another illustration of past modes of life in the district is afforded by the building now used as the Tower Inn, which was at one time a fortress of the barons of Drumlanrig, from one of whom the town charter (circa 1537) was derived. Eight years after this baronial grant, the corporate privileges were confirmed by Queen Mary, who was gratified with the hospitality she received here. The government of the town is vested in two bailies and a council; the former being elected annually by the burgesses, the latter consisting of fifteen life members and fourteen representatives of incorporated trades. The bold and enterprising spirit which characterized the borderers prior to the union of the Scottish and English crowns is now specially distinctive of the inhabitants of Hawick; and having, about the middle of last century, embarked in the manufacture of wool beyond the wants of the district, they have steadily developed a trade that at the present time gives employment in the town to a capital of L.180,000 and to 3689 hands. The carpet manufacture was the first attempted (1752), and was soon followed by the manufacture of inkle and cloth; but these have given way to the hosiery manufacture, which was first set on foot by Bailie Hardie in 1771. The bailie employed 5 men and 6 women, who produced annually, from 4 looms, about 2400 pairs of coarse stockings. Twenty years later (1791), 14 men, 51 women, and 8 looms, turned out 3500 pairs lambs' wool and 600 pairs cotton stockings—the population of the town being 2320. About the commencement of this century machinery was introduced; and in 1816 there were 7 mills, 44 engines, 100 hand jennies, and 510 stocking frames, from which 1044 operatives worked up 288,000 lbs. wool into 328,000 pairs of stockings. The subsequent progress of the trade may be seen in the following table; the statistics for 1838 and 1850 being taken from the *Annals of Hawick*, by James Wilson, town-clerk; those for 1856 being made up from returns obtained from the several manufacturing houses:—

	1838.	1850.	1856.
1. Carding Mills...	11 (1 partly by steam)	11 (6 water and steam)	12
2. Engines or Scribbling Machines	...	106 engines or 53 sets	60 sets.
3. Spinning Jennies...	...	...	74 pairs.
4. Annual consumption of Wool...	2,595,888 lbs. value £65,000	2,016,000 lbs. value £142,100	2,116,357 lbs. value £264,544
5. Quantity of Yarn Manufactured...	854,462 lbs.	1,209,600 lbs.	1,617,768 lbs.
6. Number of Stocking Frames......	1209	1200	1611
7. Number of Stockings made.........	1,049,676 pairs	...	1,670,168
8. Articles of Under-Clothing	12,552	120,000	563,104
9. Number of Weaving Looms......	226	268	332

	1838.	1850.	1856.
10. Number of Operatives	1788 (besides females)	3465	3689
11. Quantity of Soap consumed	102,899 lbs.	207,378 lbs.	191,397 lbs.
12. Annual Amount of Wages.........	£48,726	£81,650	£81,689
13. Value of Property employed in Manufactures.........	£101,861	£185,616	£178,604
14. Value of Manufactures	£140,000	£280,904	£333,217
15. Quantity of Coal consumed	...	10,000 tons	4261 tons.

As the policy of the Duke of Buccleuch, to whom nine-tenths of the soil of the parish belongs, is adverse to manufactures, this steady growth of the staple trade of the town has only been accomplished in the face of great difficulties in regard to mill sites. Though the chief manufacture is in articles of hosiery, there are also produced tweeds, shawls, blankets and flannels; and the preparation of leather, and the manufacture of gloves and candles, are carried on extensively. On Thursday there is a weekly market, principally for grain; and several fairs and hiring markets are held during the year. The trade of the town is assisted by branches of the British Linen, Commercial, and National banks, besides which there is a savings' bank. A newspaper, a literary institution, two reading-rooms, a trades' library, and some minor libraries, are evidences of the mental activity of the people; and their religious character may be judged of by the fact that there are 10 places of worship, with accommodation for the entire population of the town. These places of worship are,—2 Established, 1 Free, 3 United Presbyterian, 1 Episcopal, 2 Congregational, 1 Baptist, 1 Roman Catholic, and 1 Quaker. The ancient buildings of the town are fast disappearing, and in their stead are rising handsome modern buildings. The principal street is broad, well paved, and clean; and two bridges crossing the Slitrig render intercommunication easy, whilst an excellent bridge across the Teviot gives access from the country. Pop. of parish (1801), 2798; (1841), 6573; (1851), 7801; of town (1851), 6683. (W. E—S.)

HAWK. See index to ORNITHOLOGY.

HAWKER (German *höker*), an itinerant retailer of wares of any kind. Hawkers and pedlars are classed together, and are subject to the same regulations; but the former are supposed to carry on business on a larger scale than the latter. The legislature has always regarded this class of dealers with some degree of suspicion; and accordingly stringent enactments have been made from time to time with a view to prevent the dishonest practices so common in itinerant trading. All hawkers and pedlars must take out an annual license, the duty on which amounts to L.4; and for each horse, ass, or other beast employed by them in the transport of goods, there is an additional duty of L.4.

HAWKESBURY, a river of New South Wales, formed by the junction of the Nepean and Grose, and falling into Broken Bay 20 miles N. of Sydney. It has a course of about 130 miles, and is navigable for vessels of 150 tons to Windsor, 40 miles from the sea in a direct line, but upwards of a 100 by the windings of the river.

HAWKESWORTH, JOHN, LL.D., a distinguished *littérateur* of the eighteenth century, was born in London in 1715, or, as some say, in 1719. He was apprenticed first of all to a clockmaker, and afterwards to an attorney, but ended by adopting the profession of letters. In 1744 he succeeded Dr Johnson as redacter of the parliamentary debates for the *Gentleman's Magazine.* Eight years later he started, in company with Johnson, Bathurst, and Warton, a periodical which he called the *Adventurer.* This journal had a great success, and ran to 140 numbers, of which 70 were from the pen of Hawkesworth himself. It aimed at a high standard of moral teaching; and as it was believed to exercise a wholesome influence, its editor was rewarded by the Archbishop of Canterbury with the degree of LL.D. This distinction turned his head for a time, and his overbearing conduct alienated some of his best friends, Johnson in the number. The doctor was not unwilling to renounce his old ally, who had been honoured, as he believed, at his expense; and in truth Hawkesworth was nothing more than an imitator of Johnson, though he certainly was a good imitator. After producing some fairy tales and minor pieces, which had great success at Drury Lane, Hawkesworth published in 1761 an edition of Swift, with a life prefixed, to which Johnson bore most honourable testimony in his *Lives of the Poets.* This and other pieces of literary work which he executed gained him so much credit that he was selected to redact Captain Cook's papers relative to his first voyage. This work appeared in 1773, in 3 vols. 4to, and comprised a good narrative of the previous voyages of Byron, Wallis, and Carteret, with maps, charts, &c. The compiler received from government L.6000 as the reward of his labours, and the work was at first warmly received by the critics. It was soon discovered, however, that in his preface the editor had expressed some ideas apparently at variance with the established religion, especially on the subject of a special providence. Hawkesworth was now suspected of having aimed a secret blow at Christianity, and his simple and naïve descriptions of savage life were represented as dangerous and immoral. The real truth, however, was, that his success had made him many enemies among the critics who were jealous of his rise; and the epigrams and pasquinades of which he became the subject were in reality a tribute to his genuine merits. It is said, though with no great show of reason, that the severity with which his work came at length to be treated shortened his days. He died in November 17, 1773, and was buried at Bromley in Kent, where a monument has been erected to his memory.

HAWKING, the practice of taking wild-fowl by means of hawks. The method of reclaiming, manning, and bringing up a hawk to this exercise is called *falconry.*

Falconry is of high antiquity; but at what period hawks were first trained to this sport does not appear. The Asiatics seem to have been acquainted with it from beyond the date of history. In the time of Ctesias foxes and hares were hunted in India by means of rapacious birds; and we are told by Aristotle that "in Thrace they go out to catch birds with hawks." Also in another work, ascribed to Aristotle, the same account is to be found, with two remarkable additions—namely, that the hawks appear when called, and that they brought whatever they had seized to the fowlers, who rewarded them with part of the spoil. (*De Mirabilibus Auscultat.*, c. 128.) Whether or not the sport of hawking was practised by the Greeks has been much controverted; but it seems probable that they employed the rapacity of some of the feathered tribe in hunting and fowling.

The original Britons, with a fondness for the exercise of hunting, had also a taste for that of hawking, and every chief maintained a considerable number of birds for that sport. To the Romans this diversion was scarcely known in the days of Vespasian, but it was introduced immediately afterwards. Most probably they adopted it from the Britons; but we know certainly that they greatly improved it. In this state it appears among the Roman Britons in the sixth century. Gildas, in a remarkable passage in his first epistle, speaks of Maglocunus, on his relinquishing the sphere of ambition, and taking refuge in a monastery, and proverbially compares him to a dove, which hastens away at the noisy approach of the dogs, and with various turns and windings takes her flight from the talons of the hawk.

In after times hawking was the principal amusement of the English. A person of rank scarcely stirred out without his hawk on his hand; and in old paintings this is the criterion of nobility. Harold, afterwards king of England, when he went out on a most important embassy into Normandy, is painted embarking with a bird on his hand, and a dog under his arm; and in an ancient picture of the nuptials of Henry VI. a nobleman is represented in much the same manner. In those days, "it was thought sufficient for noblemen to winde their horn, and to carry their hawk fair, and leave study and learning to the children of mean people." The former were the accomplishments of the times. Spenser makes his gallant Sir Tristram boast,

> "Ne is there hawk which mantleth her on pearch,
> Whether high tow'ring, or accoasting low,
> But I the measure of her flight doe search,
> And all her prey, and all her diet know."

In short, this diversion was, in the good old times, the pride of the rich, and the privilege of the poor. No rank of men seems to have been excluded from the amusement. We learn from the book of St Alban's that every degree had its peculiar hawk, from the emperor down to the holy-water clerk. Vast was the expense which sometimes attended this sport. In the reign of James I. Sir Thomas Monson is said to have given L.1000 for a cast of hawks. We need not wonder, then, at the rigour of the laws tending to preserve a pleasure which was carried to such an extravagant pitch. In the 34th of Edward III. it was made felony to steal a hawk; and to take its eggs, even in a person's own ground, was punishable with imprisonment for a year and a day, besides a fine at the king's pleasure. In Queen Elizabeth's reign the imprisonment was reduced to three months; but the offender was to find security for his good behaviour for seven years, or lie in prison till he did so. Such, then, was the enviable state of the times of old England. During the whole day the gentry gave their attention to the fowls of the air and the beasts of the field; in the evening they celebrated their exploits with the most brutish sottishness; and the inferior classes, by the most unjust and arbitrary laws, were made liable to capital punishments, to fines, and loss of liberty, for destroying the most destructive of the feathered tribe.

According to Olearius, the diversion of hawking is more followed by the Tartars and Persians than ever it was in any part of Europe. "Il n'y avoit point de hutte," says he, "qui n'eust son aigle ou son faucon."

The larger falcons are used to pursue antelopes, bustards, cranes, &c.; the smaller and less powerful birds are employed to fly at pigeons, partridges, quails, and the like. The gyrfalcon, which is one-third larger than the peregrine, is imported from Tartary, and sold at Constantinople, Aleppo, and Damascus.

The falcons or hawks which were in use in this kingdom are still found in Wales, and in Scotland and its isles. The peregrine falcon (a species very generally diffused over the world) inhabits the rocks of Caernarvonshire. The same species, with the gyrfalcon, the gentil, and the goshawk, are found in Scotland, and the lanner in Ireland. But we may here notice that the Norwegian breed were, in old times, in high esteem in England, and were thought bribes befitting a king. Jeoffrey Fitzpierre gave two good Norway hawks to King John, to obtain for his friend the liberty of exporting a hundredweight of cheese; and Nicholas the Dane stipulated to give the king a hawk every time he came into England, that he might have liberty to traffic throughout the king's dominions. Hawks were also made the tenures by which some of the nobility held their estates from the crown. Thus Sir John Stanley had a grant of the Isle of Man from Henry IV. to be held of the king, his heirs, and successors, by homage and the service of two falcons, payable on the day of his or their coronation. And Philip de Hastang held his manor of Combertoun, in Cambridgeshire, by the service of keeping the king's falcons.

Hawking, though an exercise now much disused, furnishes a great variety of significant terms which still obtain in our language. Thus, the parts of a hawk have their proper names, the legs, from the thigh to the foot, are called *arms;* the toes, the *petty singles;* the claws, the *pounces;* the wings, the *sails;* the long feathers of the wings, the *beams;* the two longest, the *principal feathers;* and those next thereto, the *flags;* the tail, the *train;* the breast feathers, the *mails;* and those behind the thigh, the *pendant feathers.* When the feathers are not yet full grown, the falcon is said to be *unsummed;* when they are complete, it is *summed.* The craw or crop, is called the *gorge;* the pipe next the fundament, where the fæces are drawn down, the *pannel;* the slimy substance lying in the pannel, the *glut;* the upper and crooked part of the bill, the *beak;* the nether part, the *clap;* the yellow part between the beak and the eyes, the *sear* or *cere;* the two small holes therein, the *nares.*

As to the furniture, the leathers, with bells buttoned on the legs, are called *bewits;* the leathern thong by which the falconer holds the hawk, is called the *lease* or *leash;* the little straps, by which the leash is fastened to the legs, *jesses;* and a line or packthread fastened to the leash, in disciplining the bird, a *creance.* A cover for the head, to keep the falcon in the dark, is called a *hood;* and a large wide hood, open behind, to be worn at first, is called a *rufter hood.* To draw the strings, that the hood may be in readiness to be pulled off, is called *unstriking the hood;* the blinding a hawk just taken, by running a thread through her eyelids, and thus drawing them over the eyes, to prepare her for being hooded, is called *seeling;* a figure or resemblance of a fowl, made of leather and feathers, is called a *lure;* the resting-place, when off the falconer's fist, is called the *perch;* the place where the meat is laid is called the *hack;* and that in which the bird is set, whilst the feathers fall and come again, the *mew.*

Anything given to a hawk, to cleanse and purge the gorge, is called *casting;* small feathers given to make the bird cast, are called *plumage;* gravel given to help to bring down the stomach, is called *rangle;* the throwing up of filth from the gorge after casting, is called *gleaming;* the purging of grease, or other matter, *enseaming;* being stuffed is called *gurgiting;* inserting a feather in the wing in lieu of a broken one, is called *imping;* giving a leg, wing, or pinion of a fowl to pull at, is called *tiring.* The neck of a bird the hawk preys on is called the *inke;* and what the hawk leaves of its prey is called the *pill* or *pelf.*

There are also proper terms for the several actions of the bird. When a hawk flutters, as if striving to get away, either from the perch or hand, it is said to *bate;* when, standing too near, they fight with each other, it is called *crabbing;* when the young ones quiver and shake their wings in obedience to the elder, it is called *cowring;* when the bird wipes its beak after feeding, it is said to *feak;* when it sleeps, it is said to *jouk;* from the time of exchanging the coat, till the bird turn white again, is called *intermewing:* treading is called *cawking;* when the hawk stretches one wing after the legs, and then the other, it is called *mantling;* the dung is called *muting;* when the hawk mutes a good way behind, it is said to *slice;* when it does so directly down, instead of jerking backwards, it is said to *slime,* and if it be in drops, it is called *dropping;* when the bird as it were sneezes, it is called *sniting;* when it raises and shakes itself, it is said to *rouze;* and when, after mantling, it crosses its wings together over its back, it is said to *warble.*

When a hawk seizes, it is said to *bind;* when, after seizing, it pulls off the feathers, it is said to *plume;* when it raises a fowl aloft, and at length descends with it to the ground, it is called *trussing;* when, being aloft, it descends to strike the prey, it is called *stooping;* when it flies out too far from the game, it is said to *rake;* when, forsaking the proper game, it flies at pyes, crows, and the like, it is called *check;* when, missing the fowl, the bird betakes itself to the next check, it is said to *fly on head.* The fowl or game it flies at is called the *quarry;* the dead body of a fowl killed by the hawk is called a *pelt.* When the bird flies away with the quarry, it is said to *carry;* when, in stooping, it turns two or three times on the wing, to recover itself ere it seizes, it is called *canceliering;* when it hits the prey, yet does not truss it, it is called *ruff.* The making a hawk tame and gentle, is called *reclaiming;* the bringing one to endure company, *manning;* an old stanch hawk, used to fly and set example to a young one, is called a *make-hawk.*

The reclaiming, manning, and bringing up a hawk to the sport, cannot easily be brought under any precise set of rules. It consists in a number of little practices and observances, calculated to familiarize the falconer to his bird, and the latter to the falconer.

When the hawk comes readily to the lure, a large pair of luring bells are to be put on; and the more giddy-headed and apt to rake out the hawk is, the larger must the bells be. Having done this, and the bird being sharp-set, ride out in a fair morning, into some large field unencumbered with trees or wood, with the hawk on your hand; then having loosened the hood, whistle softly, to provoke her to fly; unhood, and let the bird fly with its head into the wind; for by that means it will be the better able to get upon the wing, and will naturally climb upwards, flying in a circle. After the hawk has flown three or four turns, then lure her with your voice, casting the lure about your head, having first tied a pullet to it; and if your falcon come in and approach near you, cast out the lure into the wind, and if she stoop to it, reward her.

You will often find, that when she flies from the hand, she will take stand on the ground. This is a fault which is very common with soar-falcons. To remedy it, fright her up with your wand; and when you have forced her to take a turn or two, take her down to the lure, and feed her. But if this does not succeed, then you must have in readiness a duck seeled, so that she may see no way but backwards, and that will make her mount the higher. Hold this duck in your hand, by one of the wings, near the body; then lure with the voice to make the falcon turn her head; and when she is at a reasonable pitch, cast your duck up just under her; when, if she strike, stoop, or truss the duck, permit her to kill it, and reward her by giving her a reasonable gorge. After you have practised this two or three times, your hawk will leave the stand, and, delighted to be on the wing, will be very obedient.

It is not well, for the first or second time, to show your hawk a large fowl; for it frequently happens that a large bird escapes from the hawk, which gives the falconer trouble, if it do not also involve the loss of the hawk. But if she happens to pursue a fowl, and, being unable to recover it, gives it over, and comes in again directly, then cast out a seeled duck; and if the bird stoop and truss it across the wings, permit her to take her pleasure, rewarding her also with the heart, brains, tongue, and liver. But if you have not a quick duck, take her down with a dry lure, and let her plume a pullet and feed upon it. By this means a hawk will learn to give over a fowl that rakes out, and on hearing the falconer's lure, will make back again, and know the better how to hold in the head.

If your hawk be a stately high-flying one, it ought not to take more than one flight in a morning. When she is at the highest, take her down with your lure: and when she has plumed and broken the fowl a little, feed her, by which means you will keep her a high-flyer, and fond of the lure.

So much for the technicalities of hawking, which, from change of times and manners, has now in a great measure fallen into disuse, though frequent attempts have been made in England during the last few years to revive it. The reader will find some admirable descriptions of this national sport in the novels of Scott, who, on this as on many other subjects, has brought the past as it were before us, rendering us familiar with its habits, customs, and amusements, and engaging our sympathy in favour of the feelings, notions, and even prejudices, with which these were associated. Among the most celebrated treatises on this subject, once so universally interesting, may be mentioned *The Book of St Albans* by Juliana Berners, 1486; *La Fauconnerie*, by Charles d'Esperon, Paris, 1605; Latham *On Falconry*, 1658.

HAWKINS, Sir John, a celebrated English seaman, was born at Plymouth about 1520. From his father, who, like himself, was a sailor, he learned the advantages of the trade with Africa. After spending his youth in trafficking with Spain and Portugal he visited the coast of Guinea, embarked a cargo of negroes (obtained partly by force and partly by purchase), and made a large fortune by selling them to the Spaniards of Hayti. He made a second voyage to the same place on the same errand in 1564, and with equal success. His third and last voyage (1567), however, was very unfortunate. He was attacked by the Spaniards in the port of St John de Ulloa, and only saved two ships of all his squadron. How different the sentiment was regarding the slave-trade in those days and in our own, may be learned from the fact that Queen Elizabeth approved all that Hawkins had done, allowed him to assume as his crest a demy-Moor in his proper colour, bound with a cord, and made him treasurer of the navy. In 1588 he was made vice-admiral of the *Victory*, and fought with such distinction against the Spanish Armada, that he was knighted by the queen. In 1595 he accompanied Drake on an expedition against the Spanish colonies in the West Indies, but he quarrelled with his colleague, and died Nov. 21st, without again distinguishing himself. There are some very interesting notices of Hawkins in Hakluyt, and also in Purchas.

Hawkins, *Sir John*, the historian of music, was born in London in 1719. His father was a builder and surveyor, and it was intended that the young Hawkins should adopt the same profession; ultimately, however, he was apprenticed to an attorney. At the expiry of his apprenticeship he began business for himself, and by industry and integrity, soon raised himself to wealth and station. In his earlier days he had been a hard student, and now in virtue of his acquirements he was admitted into the best literary society in London. Dr Johnson himself (in whose life by Boswell there are numerous and not always very respectful notices of Hawkins) admitted him into his favour, and helped forward his literary views. Hawkins was at this time a frequent contributor to the *Gentleman's Magazine* and other periodicals. His well-known taste for music gained him admittance into the Madrigal Society. In 1753 he married a lady who brought him a considerable fortune, which subsequent events so much increased, that in 1759 he retired from business and settled at Twickenham. He distinguished himself greatly as a county magistrate, and was so valuable a public servant, that in 1772 he was rewarded with knighthood by the king, to whom he had been presented as "the best magistrate in his dominions." Four years after this event appeared his *General History of the Science and Practice of Music.* The literary merit of this work is unquestionably very small, but its value as a storehouse of useful learning on the subject of music is very considerable. But Dr Burney, the rival historian of music, believing that Hawkins was trenching on a province which he considered peculiarly his, had put all the machinery of the press in operation before Hawkins' work appeared. When at last it was published it met with nothing but abuse from the entire press, and its sale was completely stopped. The next age did Hawkins the justice denied him by his own, and his work now fetches a higher price than when it was first published. The valuable musical library which he had amassed in the composition of this history, he made over to the British Museum. In 1760 Hawkins undertook an edition of Walton's *Complete Angler*, which has been frequently reprinted; but his only other work of any value, besides his *History* is his *Life of Dr Johnson*, which is rather a tribute to that great man's memory than a requisite to his fame. Hawkins himself died, May 21, 1789, and was buried in Westminster Abbey. (See the *Memoirs* and *Anecdotes* of Lætitia M. Hawkins; *Boswell's Life of Johnson*, &c.)

HAWLBOWLINE, a small island in Cork harbour. See CORK COUNTY.

HAWSE, the situation of the cables before a ship's stem, when she is moored with two anchors out forward, viz., one on the starboard, and the other on the larboard bow. This term also denotes any small distance a-head of a ship, or between her head and the anchors employed to ride her; as, a vessel sails athwart the hawse, or anchors in the hawse of another vessel.

HAWSE-HOLES, the holes in the bows of a ship on each side of the stem, through which the cables pass.

HAWSER, a large rope, intermediate between the *cable* and *tow-line* of the ship to which it belongs. It is used for various purposes, as warping, for a spring, &c.

HAY, or as it is often called, WELSH HAY, or THE HAY, a small market-town of Wales, in the parish of Hay, hundred of Talgarth, and county of Brecknock. It stands on the River Wye, near the point where the counties of Radnor, Brecknock, and Hereford converge. The town is well lighted and paved, and contains, besides various dissenting meeting-houses, a handsome parish church, rebuilt in 1838 in the early English style. It has also British and national schools, and a savings bank. The vestiges of a Roman camp near the church point to an ancient origin. The castle of Hay, a very old building, was destroyed by Henry II.; afterwards restored, and finally dismantled by Owen Glyndwr. Between two and three miles from the town is Clifford Castle, the birth-place of the celebrated Jane Clifford, better known as the "fair Rosamond," the favourite of Henry II., who built for her the maze at Woodstock, where she perished by the cruel jealousy of Queen Eleanor. There are six annual fairs at Hay, besides a weekly market on Thursday. Pop. (1851) 1238.

HAYDN, FRANCIS JOSEPH, a celebrated musical composer, born at Rohrau, a small town fifteen leagues from Vienna, in 1732. His father was a cartwright, and his mother before her marriage had been cook in the family of Count Harrach, the lord of the village. Haydn's father had a fine tenor voice, and played a little on the harp. On holidays, after church, he used to accompany his wife whilst she sung; and, when only five years old, Haydn was wont to stand by his parents and join the concert in his own way, with two pieces of wood, one of which served for a violin and the other for a bow. When loaded with years and honours, the great symphonist would often recall the music of this domestic performance; so deep an impression had its simple strains made on his soul. A cousin of the cartwright, whose name was Frank, a schoolmaster at Haimburg, came to Rohrau one Sunday, and assisted at the *trio*. He remarked that the child, then scarcely six years old, beat the time with astonishing exactness and precision. Frank was well acquainted with music, and proposed to his relations to take little Joseph to his house and teach him. They accepted the offer with joy, hoping to succeed more easily in getting Joseph into holy orders if he should understand music. Chance brought to Frank's house Reuter, *maestro di capella* of St Stephen's, the cathedral church of Vienna. He was in quest of children to recruit his choir. The schoolmaster soon proposed his little relation to him; and when he came, Reuter gave him a *canon* to sing at sight. The precision, purity of time, and spirit with which the child executed it, surprised him; but he was more especially charmed with his voice, which was naturally sonorous and delicate. He only remarked that he did not shake, and asked him the reason with a smile. The boy smartly replied, "How should you expect me to shake, when my cousin does not know how to do it himself?" "Come here," said Reuter, "and I will teach you." He then took the young Hadyn between his knees, showed him how he should rapidly bring together two notes, hold his breath, and agitate the palate. The child immediately made a good shake. Reuter, enchanted with the success of his scholar, took a plate of fine cherries, which Frank had ordered for his illustrious brother professor, and emptied them all into the child's pocket. The delight of the young musician may be readily conceived. Haydn often mentioned this anecdote, adding with a smile, that he fancied he had these beautiful cherries in his mouth whenever he happened to shake.

Young Haydn was now placed in the hands of Reuter, and accompanied him to Vienna. Haydn, in afterwards speaking of his studies under this master, said he did not remember to have passed a single day without practising sixteen or eighteen hours daily, and this he did of his own accord, for the children of the choir were not compelled to practise more than two hours. It was by this unwearied assiduity, aided by the inspirations of his genius, that Haydn, almost in the dawn of life, laid the foundation of his future eminence.

Mozart at twelve years of age composed a successful opera; but, less fortunate, Haydn at thirteen produced a mass, which his worthy master ridiculed. Convinced, after comparing his work with the compositions of others, that Reuter was right, and that nature without art was like an eagle unfledged, Haydn resolved to apply himself to the study of counterpoint. But Reuter did not teach composition; and none of the masters in Vienna were so generous as to instruct an unknown and unpatronized boy. But to this misfortune Haydn perhaps is indebted for his originality. Under a master he might have avoided some of the errors he has fallen into when he subsequently wrote for the church and for the theatre; but, upon the whole, he would certainly have been less original. He purchased the theoretical works of Mattheson, Fuchs, Emanual Bach, and Kirberg, which he studied most assiduously, labouring alone, and exercising every scientific intricacy; and so great was the pleasure he experienced in his pursuits, that, poor as he was, shivering with cold, and oppressed with sleep, seated by the side of an old worn-out harpsichord, he declared himself never to have been happier at any period of his life.

At eighteen Haydn's voice broke, and he left the class of *soprani* at St Stephen's. Obliged to seek for a lodging, chance threw him in the way of a poor peruke-maker named Keller, who received him as a son. Haydn, in the quiet obscurity of his new dwelling, was enabled to pursue his studies without interruption. His residence here had, however, a fatal influence on his future fortune. Keller had two daughters, and his wife and he arranged that one of them should marry Haydn, who, absorbed in his studies, and thinking little about love, made no objection to the proposal. He adhered to his engagement honourably in after life, but the union was an unhappy one.

Haydn now began to compose short sonatas for the pianoforte, which he sold at low prices to his few female pupils. He also wrote *minuets*, *allemands*, and *waltzes* for the *Ridotto*. By performing in concert with two of his friends a serenata in the streets, he attracted the attention of Curtz, the director of the theatre of Carinthia, who employed him to write music, which was performed with the happiest success. But Haydn's talent was not for the stage; he chose his own proper ground when in his twentieth year, and produced six trios, which, from their striking originality, at once brought him into notice. Shortly after this he published his first quartett, which every musical amateur soon had by heart. Leaving the house of Keller, Haydn went to lodge with Martinez, and became acquainted with Metastasio the poet, who taught him Italian, and instructed him in the fine arts.

Haydn struggled long against want, but at last his genius brought him into notice, and he received employment from Prince Antony Esterhazy, and his successor Nicholas, for whom he composed a number of pieces for the baryton, an instrument now scarcely ever used. Haydn did not forget his promise to his benefactor Keller; and being now in better circumstances, he married his daughter Ann, from whom he afterwards separated on account of her bad temper and conduct.

Placed now at the head of a full and excellent orchestra, and attached to the service of a rich patron, Haydn found himself in that happy union of circumstances which gives opportunity to genius to display all its powers. From this moment his life was uniform and fully employed. He rose early in the morning, dressed himself very neatly, and placed himself at a small table by the side of his pianoforte, where the hour of dinner usually found him still seated. In the evening he went to rehearsals, or to the opera which was performed in the prince's palace four times every week. Sometimes, but not often, he devoted a morning to hunting. The little time he had to spare on common days was divided between his friends and Mademoiselle Boselli, a singer of eminence. Such was the course of his life for more than thirty years; and this can alone account for the prodigious number of his productions in instrumental music, church music, and operas. In fifty years he produced no less than 527 instrumental compositions, and in the whole of these pieces he has never copied or imitated himself, but when it was his intention to do so.

Haydn wrote his best music with some labour, not from any want of ideas, but from the extreme delicacy of his taste, which he could with difficulty satisfy. A symphony would sometimes cost him a month, and a mass perhaps two. His manuscripts of one piece sometimes contain passages enough for three or four pieces. But although it seemed labour, it was not so; for he was wont to say that he never felt so happy as when at work. Nothing troubled him till the death of his patron, Prince Nicholas, in the year 1789, and the subsequent demise of his favourite Boselli; circumstances which induced him to come to England, upon the solicitations of Salomon. This musician was about to give concerts in London, and offered Haydn L.50 for each performance, which terms he accepted. Haydn was then fifty-nine years old, and he resided in England upwards of a year, and brought out there some of his finest instrumental pieces.

From England Haydn went to Germany, but he returned for a short time in 1794, and was complimented with the diploma of Doctor of Music from Oxford. He afterwards went to Austria, and did not return again to England. He was in his sixtieth year when he commenced his *Creation*, to which he devoted two years. When urged to hasten its completion he calmly said, he had been a long time about it because he intended it to last a long time. It was finished in 1798, and performed in Vienna with enthusiastic approbation. All Germany rang with its praises; in a few weeks it was printed, and spread over Europe with a rapidity before unheard of. Two years later he composed his oratorio of the *Four Seasons;* of which he used to say "It is not another *Creation*, and the reason is this: in that oratorio the actors are angels, in the *Four Seasons* they are peasants." This work terminated his musical career; the labour of it exhausted him, and he complained that he was forced to seek ideas which used to come to him formerly unsought. He wrote, however, subsequently a few quartetts, and arranged nearly 300 Scotch songs, a work which produced him about 600 guineas. At last he grew so weak, that a vertigo seized him the moment he sat down to the piano. He now seldom quitted his house and garden at Gumpelsdorf, and he became feeble in mind and body. On the morning of the 31st of May 1809 he died, aged seventy-eight years and two months. He was privately interred at Gumpelsdorf, for Vienna was at that time in the occupation of the French. Haydn's heir was a blacksmith, to whom he left the bulk of his fortune. His manuscripts were purchased by Prince Esterhazy. He left no posterity. Cherubini, Pleyel, Neukomm, and Weigl, may be considered as his disciples.

Haydn, in his symphonies, stands first in the list of the greatest instrumental authors. In sacred music he opened a new path, by which he placed himself on a level with the most celebrated composers for the church. In theatrical music he was least successful. In that department he was only an imitator. His instrumental music consists of chamber symphonies for a greater or less number of instruments, and of symphonies for a full orchestra. The first of these divisions comprehends duets, trios, quartetts, sestetts, octetts, and divertimentos; sonatas, *fantasie*, variations, and *capricci*. In the second are contained the symphonies for the grand orchestra, concertos for different instruments, serenades, and marches.

The *allegros* of his symphonies are in general full of life and spirit. They generally begin with a short, easy, and intelligible theme. Gradually, and by a procedure full of genius, this theme, repeated by the different instruments, acquires a character of mingled heroism and gaiety. There is more variety in the slow movements; in these the lofty style is majestically displayed. The phrases or musical ideas in his *andantes* and *adagios* are finely and nobly developed. Sometimes the composer is carried away by his copiousness and power; but this excess of vigour does not exclude passion and sentiment. His *minuets* are admirable, being rich in harmony and accumulated beauties. The general character of Haydn's instrumental music is that of romantic imagination. "Haydn," says Carpani, "è l' Ariosto della musica. Passeggia il suo genio per tutte le regioni dell' arte. La sua immaginazione apre i tesori d'ogni bellezza, e ne dispone a sua voglia." As a composer of symphonies and quartetts, he may be considered as the first who moulded them into that form which Mozart, Beethoven, and others, have adopted. The famous seven instrumental pieces called *Die Sieben Worte des Heylandes am Kreuze* were esteemed by the composer as his best works.

The oratorio of the *Creation* is replete with grandeur, sublimity, and beauty. The *Seasons*, with less sentiment and learning than the *Creation*, is equally admirable as an expressive and delightful composition. The ideal part of Haydn's masses is brilliant and dignified; the style is noble and full of fire. His *Agnus Dei* is full of tenderness; the *Amens* and *Hallelujahs* breathe all the reality of joy; the fugues display all the exultation of an enraptured mind. (*Le Haydine* de Carpani.) (A. H.)

HAYDN, *John Michael*, a younger brother of Francis Joseph Haydn, was born at Rohrau in September 1737. After learning the elements of music, and how to play on the harp and harpsichord, in his father's house, he entered the imperial chapel at Vienna as a chorister. His voice had the remarkable compass of three octaves, from the lowest contralto F up to highest soprano F in alt. The emperor and empress were so much pleased with his singing, that they took him under their protection. He next studied organ-playing and composition; and, by a constant examination of classical compositions, without lessons from any master, he soon acquired skill as an organist and composer.

In 1763 he was appointed music director in the chapel of the Bishop of Grosswardein, in Hungary; and in 1768 chapel-master to the Bishop of Salzburg, with the small salary of 300 florins, together with board and lodging. Afterwards this salary was raised to 600 florins. In the first year of his residence at Salzburg he married the daughter of Lipp, the organist. She bore him a daughter, who died in her third year; and the loss of this child deeply affected him for the rest of his life. At Salzburg he opened a school of composition, in which several distinguished artists were taught. In 1801 Prince Esterhazy gave him the title of his chapel-master, with a pension; but he still continued to reside at Salzburg. He died there, on 10th August 1806. He was considered by his brother Joseph as the best composer of church music of his time in Germany. He refused to allow any of his works to be published in his lifetime. Since his death, a number of his church compositions, and several of his symphonies, &c., have been published in Germany. Some pleasing specimens of his music are contained in Latrobe's *Selections*. (G. F. G.)

HAYDON, Benjamin Robert, historical painter and writer, was descended from an old Devon family, the Haydons of Boughwood, Cadby, and Woodbury. He was an only son and was born January 26, 1786. His mother was the daughter of the Rev. Benjamin Cobley, rector of Dodbrook, Devon, whose son, General Sir Thomas Cobley, signalized himself at the siege of Ismail. His father was a man of great literary taste, and was well known and esteemed amongst all classes in Plymouth. Haydon, at an early age, gave evidence of his taste for study, which was carefully fostered and promoted by his mother. At the age of ten he was placed at Plymouth grammar school where his love of study and painting was still further developed by the principal, himself a man of refined taste and great artistic acquirements. At the age of fourteen he was sent to Plympton St Mary school. He completed his education in this school where Sir Joshua Reynolds also had acquired all the scholastic knowledge he ever received. On the ceiling of the school-room was a sketch by Reynolds in burnt cork, which it used to be Haydon's delight to sit and contemplate. Whilst at school he had some thought of adopting the medical profession, but he was so shocked at the sight of an operation that he gave up the idea. A perusal of Albinus, however, inspired him with a love for anatomy; and Reynolds' discourses aroused within him his smouldering taste for painting, which, from his earliest childhood, had been the absorbing idea of his mind. Sanguine of success, full of energy and vigour, he started from his parental roof May 14, 1804, for London, and entered his name as a student of the Royal Academy. He began and prosecuted his studies with such unwearied ardour that Fuseli wondered when he ever found time to eat. At the age of twenty-one (1807) Haydon exhibited, for the first time, at the Royal Academy, "Repose in Egypt," which was bought by Mr Thomas Hope the year after. This was a good introduction to the young artist, who shortly after received a commission from Lord Mulgrave and an introduction to Sir George Beaumont. In this year also he finished his well-known picture of "Dentatus," which, though it brought him a great increase of fame, involved him in a violent and life-long quarrel with the Royal Academy, whose committee had hung the picture in a small side-room instead of in the great hall. Haydon saw in this act an attempt to crush him by depriving him of his due; and his subsequent conduct was disastrous chiefly to himself. In 1810 his difficulties began, though he was still receiving from his father an allowance of L.200 a-year. Bad luck also attended his struggles for professional advancement; for, though he put his name down for admission into the academy, he did not obtain a single vote. His disappointment was embittered by the controversies in which he now became involved with Leigh Hunt, with Sir George Beaumont, for whom he had painted his famous picture of "Macbeth," and Mr Payne Knight, the last of whom had denied the beauties as well as the value of the Elgin Marbles. The "Judgment of Solomon," his next production, gained him L.700, besides L.100 voted to him by the directors of the British Institution, and the freedom of the borough of Plymouth. Success rewarded his efforts. West wept on beholding the "Pale Fainting Mother;" and Miss Mitford addressed to him one of her best sonnets. To recruit his health and escape for a time from the cares of London life, Haydon joined Wilkie in a trip to Paris; he studied at the Louvre; and on his return to England produced his "Christ's Entry into Jerusalem," which afterwards formed the nucleus for the American Gallery of Painting, which was erected by his cousin John Haulland of Philadelphia. With such professional renown as he had now acquired, Haydon again aspired for admittance into the Royal Academy, and was again unsuccessful. Amid the trials and difficulties of this period of his life, he found time to write a long and elaborate essay on Painting for the *Encyclopædia Britannica*. This essay has been twice reprinted. (See article Painting.) Whilst painting "Lazarus," his pecuniary difficulties increased, and for the first time, he was arrested but not imprisoned, the sheriff-officer taking his word for his appearance. Amidst all these harassing cares he married. In 1823, Haydon was lodged in the King's Bench, where he received the most consoling letters from the first men of the day. Whilst a prisoner he drew up a petition to Parliament in favour of the Elgin Marbles, which was presented by Mr Brougham. He also produced the picture of the "Mock Election," the idea of which had been suggested by an incident that happened in the prison. The king (George IV.) gave him L.500 for this picture, and Haydon was enabled to purchase his release. Haydon's other pictures were—1830, "Eucles," and "Punch;" 1831, "Napoleon at St Helena," for Sir Robert Peel; 1832, "Xenophon, on his Retreat with the 'Ten Thousand,' first seeing the Sea at Thebes;" "Waiting for the *Times*," purchased by the Marquis of Stafford; "The First Child;" "Reading the Scriptures;" "Falstaff;" and "Achilles playing the Lyre." In 1834 he completed the "Reform Banquet," for Lord Grey—this painting contained 197 portraits; 1843, "Curtius Leaping into the Gulf;" and "Uriel and Satan." When the competition took place at Westminster Hall, Haydon sent two Cartoons, "The Curse" and "Edward the Black Prince," but had not the good fortune to succeed with either. He then painted "The Banishment of Aristides," which was exhibited with other unfinished productions under the same roof where Tom Thumb was then making his debût in London. The exhibition was unsuccesful; and the artist's difficulties increased to such an extent that whilst employed on his last grand effort, "Alfred and the Trial by Jury," overcome by debt, disappointment, and ingratitude, he wrote, "Stretch me no longer on this rough world," and put an end to his existence, June 22, 1846, in the 61st year of his age. He left a widow and three children, who, by the generosity of their father's friends, were rescued from their pecuniary difficulties, and comfortably provided for; amongst the foremost of these friends were the late Sir Robert Peel, Le Comte A. D'Orsay, Mr Justice Talfourd, and Lord Carlisle. Haydon began his first lecture on painting and design in 1835, at the Mechanics' Institution, and afterwards visited all the principal towns in England and Scotland. His delivery was energetic and imposing, his language powerful, flowing, and apt, and abounded with wit and humour; and to look at the lecturer, excited by his subject, one could scarcely fancy him a man overwhelmed with difficulties and anxieties. It has been said that the height of Haydon's ambition was to behold the first buildings of his country adorned with historical representations of her former glory. He lived to see the acknowledgement of his principles by government in the establishment of schools of design, and the embellishment of the new houses of parliament, but in the competition of artists for the carrying out of this object. The Commissioners (amongst whom was one of his former pupils) considered he had failed; and whilst employed in a series of gigantic paintings, which were executed to show to the world the falseness of their judgment, he ended his life, as we have before mentioned. Haydon was well versed in all points of his profession; and his *Lectures* which were published shortly after their delivery, showed that he was as bold a writer as he was a painter. Although many of his early productions in portrait-painting were truthful and striking (even at the early age of eighteen, he had given evidence of great talent), Haydon never pursued this branch of his art, except as a means for enabling him to carry out his ideas of high art. To form a correct estimate of Haydon, it is only necessary to read his autobiography. He there solves the mystery of his own life as unconsciously and as fully as Montaigne and Rousseau. It is one of the most natural books ever written. The author seems to have daguerreotyped his feelings and sentiments without restraint as they rose in his mind, and his portrait stands in these volumes limned to the life by his own hand. His mind was a peculiarly ill-regulated one. It was not governed by any ruling principle; his love for his art was rather a passion than a principle. He went to London to seek his fortune, believing, as young men will, in patrons. He found patrons difficult to manage; and not having the tact to lead them gently, he tried to drive them fiercely. He failed of course; abused patrons and patronage, and intermingled talk of the noblest independence with acts of the grossest servility. It was to himself, and to himself only, that he owed his frequent disappointments and his wretched life. He was self-willed to perversity, but his perseverance was such as is seldom associated with so much vehemence and passion as belonged to him. With a large fund of genuine self-reliance, he combined a vanity so boundless that it would have been ludicrous if it had not been pitiable. To the very last he believed in his own powers, and in the ultimate triumph of art, though he seems to have hoped for art only through himself as its successful champion. In taste and judgment he was alike deficient, in everything at least that concerned himself. Hence the boisterous and exaggerated tone of self-assertion which he assumed in his advertisements, catalogues, and other appeals to the public. He proclaimed himself the apostle and martyr of high art, and believed himself to have on that account, a claim on the sympathy and support of the nation. It must be confessed that he often tested severely those whom he called his friends; and few men's friends ever stood the test so well. All the money that he borrowed and begged, he, no doubt, intended to repay; and there is no reason why he should not have fulfilled his intention, as his contemporary and fellow-sufferer, Etty, did. Had he possessed even ordinary prudence, he might have reached the haven sooner and more quietly even than the other. Every reader of his autobiography will be struck at the frequency and fervour of the short prayers interspersed throughout the work—"the begging letters despatched to the Almighty," as they have been called. Haydon had an overwhelming sense of a personal, overruling and merciful providence, which influenced his relations with his family, and to some extent with the world. Whatever he may have been as an artist and a citizen, his conduct as a husband and as a father is beyond all praise.

HAYE, La, a small town of France, department of Indre-et-Loire, on the Creuse, 30 miles S. of Tours. It is only remarkable as being the birth-place of Descartes: the house in which he first saw light is still carefully preserved. Pop. about 1500.

HAYLE, a small seaport of Cornwall, on the inner basin of St Ives' Bay, 5 miles S.E. of St Ives. It has two large iron foundries and steam-engine factories. It carries on an active trade, and the harbour is accessible to vessels of 200 tons.

HAYLEY, William, the friend and biographer of Cowper, was born at Chichester in 1745. After graduating at Cambridge he embraced the profession of the law; but finding it little congenial to his tastes he abandoned it, and retired to his patrimonial estate of Earthem in Sussex. His intention was to spend the remainder of his days in rural quiet, with such a seasoning only of literary activity as might defy ennui, and give a zest to his life. In his retirement he made the acquaintance of Cowper, and this acquaintance soon ripened into a friendship that remained close and unbroken till the great poet's death. Hayley himself survived till November 20, 1820. During his lifetime Hayley was held in high estimation, partly for his literary qualities, which were not wholly contemptible, but more for his position in society, his taste and acquirements, which were both considerable, and his fortune which was large. In his prime, too, there was no one to dispute the poetic laurel with him; the great of the eighteenth century had died out, and those of the nineteenth had not yet been acknowledged; and thus the French proverb became true in his case, which says,—"Au royaume des aveugles les borgnes sont rois." His best piece is his *Triumph of Temper*, which still enjoys a share of popularity; but he also wrote with ease and elegance the *Vers de Société*, so much in vogue in his day. His prose essays on *Painting*, *History*, *Epic Poetry*, and *Sculpture*, are quite above mediocrity, and he did a real service to literature by his *Life of Cowper*. His life of himself, from which the foregoing details are chiefly taken, is a sufficiently readable work.

HAY-MAKING. See Agriculture, chap. viii., *Herbage and Forage.*

HAYNAU, or Hainau, a town in the Prussian province of Silesia, government of Liegnitz, and 9 miles W.N.W. of the town of that name. The inhabitants are chiefly employed in woollen and linen weaving. In the vicinity are some good veins of fuller's earth. Pop. (1849) 4187.

HAYTI, Haiti, San Domingo, or Hispaniola, one of the largest and most fertile of the West India islands, extending in length from E. to W. about 390 miles, and in breadth from 60 to 150 miles, is situated between N. Lat. 17. 37. and 20. 0., and between W. Long. 68. 20. and 74. 28. It is called Hayti, or the Highland country, by the natives, from the mountains with which it abounds, especially in the northern part. The country was formerly divided between the Spaniards, who were the earliest European colonists, and the French. The line of demarcation which separated these two divisions commenced on the S. side from the Pedernales or Flint River, and extended in a waving direction to the River Massacre on the N. side. The country to the W. of this line belonged to the French, while that on the E. side formed the Spanish part of the island. By far the greatest portion of the country was in the possession of the Spaniards; their division being reckoned 220 miles in length by 120 in breadth, of which, though a considerable part consists of mountains, these are said to be little inferior in fertility to the champaign country, and to be equally capable of cultivation. The French division is of an extremely irregular figure. The land is deeply penetrated by the Gulf of Gonaive, and is in some parts 170 miles in length, whilst in others it is not 30. It is nearly of the same breadth as the Spanish division.

General description of the coast.

Great part of the coast of this island is rocky and dangerous, affording but an imperfect shelter to vessels overtaken by storms. Many of the shipping-places on the southern shore are nothing more than open bays, which lie exposed to the storms and hurricanes of the autumnal months. The harbour of San Domingo, formerly thought so commodious and secure, has become too shallow to admit vessels of large burden. There are, however, besides roadsteads and several small harbours, the Bays of Neyba and Ocoa on this coast. Into the former flows the River Neyba, which receives vessels of 30 tons burden; its stream, before entering the ocean, divides itself into various channels, which, annually changing, confound the pilot, and render the navigation difficult. Ocoa Bay is a large and convenient watering-place, with several small rivers falling into it. The entrance is two leagues across, and it gradually widens to nearly six. On the E. side of this bay is the safe and capacious port of Caldera. On the S.E. coast is the great Bay of Samana, which, in point of size and situation, is one of the most important on the island. From Cape Raffael, which forms the southern point of entrance into the Bay of Samana, to the opposite side of the island or peninsula of Samana, the distance is 18 miles, which is closed in by a bulwark of rocks and sands, the entrance only being left clear, with a safe and deep channel between the shore of Samana and several detached islands. This bay is about 60 miles long, and is surrounded on every side by a fertile country, suited to all the purposes of trade. Within the compass of this bay whole fleets might ride at anchor in perfect security. The River Yuna, after being joined by the Cambu, and meandering through the rich plains of La Vega Real, falls into the Bay of Samana after a course of nearly 100 miles. Bahia Ecossaise (or Scotch Bay), which is situated on the N. side of the peninsula of Samana, is a dangerous rocky place. Thence to Puerto Plata the coast extends about 60 miles in a N.W. direction, and in this space stands Balsama Bay, which has only 14 feet depth of water, and is of difficult navigation. The harbour of Puerto Plata was first discovered by Columbus; the entrance is narrow but safe, and the neighbourhood is rich in every species of timber trees. There are several other small harbours and bays on this side of the island; but the coast is in general rocky and dangerous.

Soil and surface. A country of such magnitude as Hayti, containing mountains of great height, with valleys of corresponding extent, necessarily comprises great variety of soil. In general, however, it is fertile in the highest degree, being everywhere drained by copious streams, and yielding in abundance every species of vegetable produce which can minister either to the luxury or comfort of man. The soil consists principally of a rich clay, sometimes mixed with gravel, lying on a substratum of rock. That part of the island formerly occupied by the French is mountainous, but fertile and well wooded, and containing mines both of silver and iron. The Spanish part of the island is mountainous in many parts; whilst in other parts the country is spread out into extensive plains. These are generally in a state of nature, covered with herbage, or with woods of immense growth and the most luxuriant foliage. The mountains intersect the island in two principal chains from E. to W. From these secondary and partial ridges diverge irregularly in different directions, forming beautiful and fertile valleys, with numerous streams. The highest mountains of the interior, particularly those of Cibao, rise to the height of 7200 feet above the level of the sea. To the N. of the capital is the valley called Vega Real or Royal Plain, which is by far the largest and finest in the island. Westward it extends to the old French line of demarcation, and in this part it is drained by the River Yacki; to the E., where the River Yuna flows for the space of 50 miles, it projects to the head of the Bay of Samana, and is drained by numerous smaller streams, which cross it in various directions. This valley may be said to extend in length about 140 miles, and in breadth from 20 to 30. Other plains also, of less extent, but of equal fertility and of easy access, are everywhere found interspersed among the mountainous tracts. Westward from San Domingo, along the southern coast, is the valley of the River Banis, extending from Nisao to Ocoa. Here the pasture is good; but the country is not so well watered as in the other parts of the island; an inconvenience which is sensibly felt by the cattle during the dry months. Further to the westward and to the N. other valleys are found; but where the land, as in this island, is everywhere intersected by ranges of mountains, it is impossible, in any general sketch, to describe particularly that continual succession of hill and dale which diversifies the face of the country. Eastward from the capital are those immense plains called *Los Llanos*, which stretch out to a vast extent on a dead level. They are covered with herbage, and the eye wanders unobstructed over the wide expanse of waving grass, which is occasionally diversified by natural clumps of shrubs. These plains occupy almost one-sixth part of the island, extending nearly to its eastern coast, being a distance of more than 90 miles, by about 30 wide. They form an immense natural meadow, covered with pasture for vast herds of cattle, which belong to more than a hundred different owners.

Climate. San Domingo has a hot moist climate; but the heat is mitigated by the regularity of the sea-breeze, and by the contiguity of the mountains. In the plains the thermometer rises to 96°, sometimes to 99°; but in the mountainous tracts it seldom rises above 78°. In the most elevated parts a fire is frequently necessary. In those situations meat may be kept for several days, and in the morning hoar frost is frequent. The seasons, as in tropical countries, are divided into the wet and the dry. The rains are periodical, and are heaviest in May and June, when the rivers, which at other times scarcely supply water for a continued stream, overflow their banks, and, with an impetuous torrent, sweep over the neighbouring plains. The climate of San Domingo is unhealthy to Europeans, owing to these violent heats and heavy rains; and hence all metals, however bright their original polish, soon contract a tarnished appearance. This is more observable on the sea-coast, which is also more unhealthy than the interior of the island. Hurricanes are not frequent, but in the southern parts of the island violent gales of wind, generally preceded by a closeness and sultriness in the atmosphere, frequently occur. These, however, are not attended with such fatal effects as the hurricanes in the Windward Islands.

Rivers. The island of Hayti abounds in rivers and smaller streams, which flow from the mountains in the interior, in different directions, to the sea. Of these, the principal are the Haina, the Nigua, the Nizao, the Ozama, the Neyba, the Ocoa, the Yane, and the Santiago or river of Monte Christi. Near the S. part of the French line of demarcation is the beautiful lake of Henriquillo, which is about 60 miles in circumference; and though it is about 25 miles from the sea, its water is perfectly salt, and of the same specific gravity as that of the ocean. The same fishes are also found in it, such as the shark, seal, porpoise, &c.

Vegetable productions. The fertile soil of Hayti is distinguished by the variety of its vegetable productions, many of which are rare and valuable. The mahogany tree grows to a great size, and is of very fine quality. The manchineel tree affords a beautiful species of wood, richly veined like marble, and susceptible of the finest polish. Several species of dye-woods are produced in the forests. There is a tree called the jagua, the fruit of which is accounted a delicacy by the natives; and of which the juice, as clear as water, makes a stain on linen which is indelible. Different kinds of guaiacum are found, as also of several other woods with the same properties, which grow unnoticed and nameless in those unexplored forests. The sideroxylon or iron-wood, remarkable for hardness, as its name implies, is abundant; and the oak also, which differs in appearance from the European oak, frequently furnishes beams of from 60 to 70 feet in length. On the N. side of the island are extensive forests of pine, which is much used for the purposes of shipbuilding; and Brazil-wood is found on many parts of the coast. The satin-wood of this island is heavier than that of the East Indies, and it takes so fine a polish that it does not require to be varnished. The cotton tree is the largest of all the vegetable productions, and is formed into the lightest and most capacious canoes. Every variety of the palm tree is found in the woods, of which they form a principal ornament. The palmetto or mountain cabbage is an erect and noble tree, which grows to the height of 70 feet, with esculent leaves at the top. In the congenial soil of this fertile island the sugar-cane, cotton and coffee plants, grow in the greatest luxuriance. There is also the calabash, the fruit of which serves as a substitute for earthenware; the plantain, the staff of life in the West Indies; vanilla, which is found indigenous in the unfrequented woods; quassia or simarouba, which is a tall and stately plant, waving gracefully in the wind; sarsaparilla, indigo, tobacco, turmeric, ginger and rice plants. The fruits and nutritive roots of San Domingo are nearly the same as those of Jamaica; but they are more abundant, and extremely fine. Of these may be enumerated the choux caraib, or Indian kale, with a variety of other vegetables that come under the same denomination; the avocato or vegetable marrow, the melon, sapadillo, guava, pine-apple, bread and jack fruit, mango, nuts, rose-apple, plums, &c., of many different species. Flowers in endless variety and splendour adorn the wild scenery of the woods, and exhale their fragrance in the desert air.

Geology. Little is known of the geological structure of the island, but a limestone containing vestiges of marine shells is the prevailing formation. Mineral springs exist in several parts. The most noted in the eastern part of the island are those of Banica, Yaya, and Pargatal; and in the west the chalybeate of St Rose, the saline of Jean Rabel, and the alkaline sulphur waters of Dalmarie. The mineral products are various and rich, and include gold, platina, silver, quicksilver, copper, iron, tin, sulphur, manganese, antimony, rock-salt, bitumen, jasper, marble, opal, lazulite, chalcedony, &c. The gold mines of the Chibao Mountains, which, in the sixteenth century, were very productive, have been abandoned, and at the present day gold is obtained only from the washings in the northern rivers. None of the mines, indeed, are successfully worked, and hence these sources of wealth are reserved for the industry of future generations.

Animals. The indigenous quadrupeds of this island were confined to four species, which the Indians called Hutia, Quemi, Mohuy, and Cory. Of these, all are believed to be extinct except the first. Horned cattle, hogs, sheep, goats, horses, mules, and asses, have been introduced from Europe, and have multiplied prodigiously in the wild and extensive pastures of the interior. Wild fowl are abundant, consisting of various species of ducks, pigeons, the flamingo, the wild peacock, the mimic thrush or mocking bird, the banana bird, the Guinea fowl, the ortolan, and parrots of various species. The rivers abound with fish, some of which are very delicate. Turtle of all kinds are taken, and the land-crab is much esteemed. The serpents are not dreaded; but the centipedes, which are frequent in old buildings, are large and dangerous. The scorpion is rarely seen; but the venomous crab-spider, which is equally dangerous, is sometimes met with.
